A promising and fairly recent concept of virtual touch has been developed by Demirci (2007). Virtual touch refers to the online sense of touch that consumers perceive in a virtual product experience when they are exposed to a 3-D format of a product through a computer screen. Findings from the same author suggest that there is a positive causal relationship between the interactivity of an object and virtual touch, and in creating such increases purchase intentions and product knowledge.

In spite of the multiple studies that find a positive effect of touch on consumer's perceptions, there are other researchers who have found that even though consumers like to touch products, they do not like the idea that a product has been touched by other consumers, and they may even respond in a negative way to such products (Argo, Dahl & Morales, 2006). Nevertheless, there is also evidence that positive contagion exists in certain situations, for example when the person who touches the product is attractive and from the opposite sex (Argo, Dahl, & Morales, 2008).

Touch and Consumer's Response/Behavior

Early studies of touch in the marketing area were interested in the effects of interpersonal touch on consumer's behavior. Previous findings from these studies suggest that interpersonal touch can ensure sampling, purchase of a product and increase the amount of shopping (Smith, Gier & Willis, 1982; Guéguen & Jacob, 2006). Also, interpersonal touch has been found to positively influence evaluations of the store, compliance with a request, shopping time, satisfaction, and tipping (Hornik, 1992a; Hornik, 1992b; Lynn, Le, and Sherwyn, 1998).

The influence of touch on affective response and persuasion has also been studied. Interestingly, the incorporation of touch into marketing messages has been found to create an affective response, which leads to a positive effect on persuasion, in particular for people who have high autotelic need for touch

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Peck & Wiggins, 2006). Concordantly, Peck and Wiggins (2011) found that individuals with high autotelic need for touch are more persuaded when a haptic element is present, regardless of their involvement with the message. However, a haptic element increases persuasion for low autotelics under conditions of low versus high involvement with the message. Also, Peck and Childers (2006) found that people with a higher autotelic need for touch were more likely to purchase impulsively than lower autotelic individuals. Furthermore, consumers high in instrumental need for touch evaluate products in a more positive way and show stronger brand-self connection when a force feedback (haptic) stimulus is present than when no stimulus is present (Jin, 2011).

Consumers inability to touch products has been an ongoing challenge for those who use the Internet to commercialize products. Consumers often express unfavorable or frustrating feelings related to such inability to product touch (Peck & Childers, 2003a; Balaji, Raghavan, & Jha, 2011), in particular are those with high levels of NFT, which makes them reluctant to adapt or use online shopping channels (Citrin, Stem, Spangenberg & Clark, 2003). Although there is evidence that suggests touch can be perceived even if consumers cannot actually touch the product (Balaji, Raghavan, & Jha, 2011; Demirci, 2007), there is a lack of studies addressing this issue. Hence, the primary contribution of this research is establishing that touch could be compensated in a certain manner by non-touch commercial channels allowing for certain verbal and non-verbal stimuli.

E-Commerce

Inability to Touch Products as a Barrier for Online Shopping

Electronic commerce (e-commerce) can be defined as the purchase of products, services, or information through Internet platforms. Similar to traditional commerce, e-commerce consists of selling and buying from business-to-business, business-to-consumer, and consumer-to-consumer. One of the main differences between making a purchase through traditional commerce or through e-commerce is the opportunity that the buyer has to physically experience the product (Ashwini & Vincent, 2017). As previously mentioned, consumers evaluate products through touch and the lack of touch in e-commerce is a barrier for those consumers who are not confident to buy products when they cannot touch them making some consumers to avoid online shopping channels (Citrin, Stem, Spangenberg & Clark, 2003). However, despite consumer's inability to touch products in an online context, the use of e-commerce channels has increased steadily in the past years.

Use of Written Descriptions and 2D Images to Convey Information Online

Although consumers are not able to experience the product physically, online stores can provide visual information about products through written descriptions, and more importantly, through 2D images such as pictures and videos. In fact, until now most online stores employed these presentation formats to present and provide product information; specifically, written descriptions provide information such as product size, weight, warranty policies and 2D images are used to depict visual appeal of the product (Jiang & Benbasat, 2007). However, these product presentation formats lack of richness to provide information such as feel, try and touch of a product (Rose, Khoo, & Straub, 1999). But while research has recognized touch as an important aspect, there has been relatively few efforts to understand whether and how to compensate touch in an online context.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Integration of Intelligent Techniques for E-Commerce

The purpose of the artificial intelligence discipline is to understand human intelligence and construct computer programs that can imitate intelligent behavior. Intelligence techniques have been applied in several areas of science such as engineering, education, and business, among other areas. Particularly of interest for the present research, intelligent techniques have been applied for e-commerce platforms to correlate products and forecasting of sales, for user profiling in order to provide users appropriate recommendations, website ranking, etc. (Das, 2016; Prasad, 2003; Singh & Mehrota, 2016; Verma & Singh, 2017). There has been research on the use of artificial intelligence and machine learning techniques to predict consumer repurchase intentions, to analyze reviews in online retailing, and to model the relationships between sensory attributes and fabric properties (Chen et. al, 2014; Jeguirim et.al, 2012; Kumar, Kabra, Mussada, Dash, & Rana, 2017; Lin, Liaw, Chen, Pai & Chen, 2017). However, the present research identifies an opportunity to contribute to previous works on the area of intelligent techniques by adopting a consumer's perspective of the tactile attributes that consumers consider relevant for different types of products and how they cope to obtain this type of information online. Therefore, the following research questions are established.

Research Questions

This research focuses on the following question as its main guide through this study: How do consumers obtain tactile information in an online shopping context? Additionally, this research also addresses the following questions: Which product characteristics are evaluated through touch? Which products are considered important to touch before purchase? Which of the online product presentation formats are more effective in providing tactile information?

METHODOLOGY

As suggested by previous literature, qualitative methodology helps to understand a phenomenon in a specific context; generally, this type of research uses interviews, focus groups, case studies, and observation among other research methods (Bryman, 1984; Creswell, 2007; Eisenhardt, 1989; Smith, 1983; Spiggle, 1994). For the present research a qualitative approach was used to explore whether tactile information can be obtained from online stores. Specifically, data for this research consisted of eleven in-depth interviews. In the first part of the interview, participants were asked questions regarding the experience of buying in a traditional store. The second part of the interview was focused on online shopping. Finally, the third part consisted on questions about product presentation formats (written descriptions, photos, videos) used by online stores that could better provide tactile information about the products. Interviews were conducted at the participant's homes during a period of two weeks. Each interview was audiotaped and lasted between 30 and 45 minutes. After that, the categorization and analysis stage began, and then comparisons between the informant's responses were made to identify differences and commonalities.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sample Profile

This research was conducted in Monterrey, Mexico, one of the three largest cities in the country with an estimated population of over five million in 2015 (Instituto Nacional de Estadística y Geografía- The National Institute of Statistics and Geography). The sample consisted of women from 18 to 27 years old, of the economic strata of A/B and C+. All of the participants were single and either college students or graduated professionals. See the Appendix for a complete list of names and descriptions of the participants. During the interviews it was noticed that six of the women participating in the study had never bought in an online store and the other five had purchased online at least one time.

FINDINGS

Consumers' Perceptions of Online Shopping

Participants in this study were asked for their perceptions on e-commerce. Perceived advantages of buying online were recognized and classified in this paper as: convenience, savings, variety and stock availability (see Table 1). Convenience refers to the type of access the store offers, i.e. every day and at any time (24/7), to its ease of use, and to the ability consumers have to find things they cannot find in their own city without the need to travel. Shopping online also comes with the advantage of saving time by not having to wait in a line or to wait to be attended by an employee; and, saving money because they can find products at lower prices. Additionally, variety refers to the advantage of being able to access different stores at the same time by simply opening a new window in the internet search engine which permits consumers to evaluate a greater amount of products. Finally, as mentioned by several participants, an additional advantage of e-commerce over going to a physical store is the stock availability, because the products shown in the online store are almost always available to buy.

It is more probable that you can find the size and there is more variety than in a store (physical). (Fabiola, age 18)

There are brands that you can buy at a lower price...there are products that you do not find here (in the city or country). (Tania, age 24)

I can do it (buy) whenever I want because the store (online) is also open at night... (Ana Rosa, age 25)

Despite the advantages previously mentioned, participants in this study also consider several disadvantages of purchasing online such as: uncertainty, delivery time, financial risks, and lack of physical experience with the product (see Table 1). As mentioned in the data collection, uncertainty comes from not knowing exactly what can be expected of the product quality and if the product will actually look as it is displayed on the store's web page. Delivery time is also perceived as a negative aspect of e-commerce when the waiting time is long (more than a week), but usually this disadvantage is compensated with the lower prices offered online and with the time saving in not having to wait in a line. Additionally, there are perceived financial risks to buying online, some of the participants actually mentioned that they do not buy online because they do not want to provide their credit card information. Finally, not

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

being able to physically experience the product by touching or trying the product was also mentioned as a disadvantage of online shopping.

Precisely everything that you can not do, you can not touch it or try it on, you can not ask people (employees) which material is... (Isabel, age 27)

You do not know if the product is what you expected...also there is the risk that the package may not arrive. (Gaby, age 21)

The fact that you have to give a credit card...the time of delivery, that I do not have the product at that moment. (Sarai, age 22)

Table 1. Advantages and disadvantages of shopping online

Advantages	Disadvantages
• Convenience • Savings • Variety • Stock Availability	• Uncertainty • Delivery times • Financial risks • Lack of physical experience

Shopping and Touch

Participants were asked about the experience of shopping in a physical store. All of the participants commented that when they were at a store they usually touched a great variety of products either for evaluation or just for hedonic purposes (pleasure), because they like the haptic feeling of certain products. Specifically, the majority of the participants who bought online said they touch products to obtain information. In contrast, the majority of the participants who had never purchased online answered that they touch products for pleasure.

To evaluate if is of good quality, to obtain information. (Isabel, age 27)

For both, for pleasure to know if it feels good or not and to obtain information. (Naila, age 24)

Additionally, participants were asked whether they imagine a sensation of a product prior to touching it and whether this perception is generally confirmed or disconfirmed after they actually touch it. The majority of participants mentioned that they do imagine how a product will feel when they look at it at a store. Most of those who had bought online commented that, generally, their perceptions about how the product feels does not change after touching it. In contrast, most of those who had never purchased online commented that generally their first perception of the product's sensation does change after touching it.

It (perception) can be confirmed or disconfirmed... because there are some fabrics that look very nice but when you touch them they do not feel nice. (Naila, age 24)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

It changes only when they are materials that simulate to be another material...but generally it does not change. (Ana Rosa, age 25)

No, generally they feel how I imagined... (Tania, age 24)

One time I was looking at some dresses, they looked really nice, but then I went to touch them and it was not the fabric I imagined...it does change my perception when I touch the garments. (Pamela, age 25)

Participants in this study mentioned that touching products is important because they considered that by touching the product they could obtain information of certain characteristics that help them evaluate particular aspects of the product. Therefore, they were asked to mention products that they usually prefer to touch before purchasing them and the specific characteristics that they evaluate when touching that type of product. In particular, participants of this study mentioned nine product categories (see Table 2) that they like to touch before purchase and the tactile characteristics that they evaluate for these products. In general, these characteristics help them to determine product's durability, quality, and comfort.

Very, very important because then you can know if it really is of good quality. (Jessica, age 18)

Interestingly, all participants mentioned that they touch clothes and indicated they evaluated this product category by a greater list of characteristics than for the other product categories mentioned. Specifically, they mentioned that through touch they evaluate the texture of the garment to know if it is soft, smooth or itchy, in fact itchiness is an important characteristic that most of participants mentioned. If the product is evaluated as too itchy they avoid buying it. Through touch they also evaluate the weight of the garment, in general, the less weight the more comfortable they consider the product to be. Product thickness helps them to evaluate temperature insulation, for example if the garment is very thin they consider that it will be fresh, and if the fabric is thick, then they consider it to be warm. Thickness also helps them to evaluate the transparency of the product; in fact they mentioned that it is important for them to be able to actually put their hands under the garment to assess transparency. Finally, through touch they also evaluate a fabric's stretchiness to obtain an idea of whether the product will fit them or not.

I like to feel the texture...I like a lot to feel the material, is one of the most important factors that I evaluate. (Elean, age 23)

That they are soft, that they do not itch, that they do not get damaged in the first wash...smoothness, fabric thickness. (Tania, age 24)

How hot it (fabric) can be, how heavy, or if it is of good quality or not. (Naila, age 24)

Fabric thickness, smoothness, if it is transparent. (Elean, age 23)

Participants who talked about shoes expressed that they need to touch them to evaluate the material. For instance, by touching the shoe they are able to know if the product is made out of leather or other material and whether they will feel comfortable or not wearing them. Participants who discussed food, specifically fruits and vegetables, mentioned that they evaluate freshness through touch, in general they

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

noted that the firmer the fruit or vegetable is the more fresh they consider it to be. Cosmetics are also products that are considered by some participants as important to touch, because they want to evaluate characteristics such as greasiness and moistness, in general they dislike greasiness and look for moistness. Additionally, for accessories such as earrings, rings, and bracelets participants indicated they need to touch them to evaluate weight, some of them mentioned that the heavier the accessory the greater the perceived quality, but the less comfortable they consider it to be. Quilts are evaluated through touch for smoothness and weight to evaluate comfort, as participants pointed out, they prefer quilts that are warm but smooth and light weight. Moreover, as with shoes, texture and thickness are characteristics evaluated for other leather products; participants look for leather products that are thick and smooth to assess their quality. Finally, participants like to touch mobile phones and mobile accessories prior to purchase to evaluate the material's weight and firmness, their answers were mixed regarding the product's weight, but all of the participants who mentioned this product category agreed that they seek for firmness or hardness in this product to consider if they are of good quality.

Table 2. Characteristics of products evaluated through touch

Product	Characteristics
Clothes	Texture (softness, smoothness, itchiness), Weight, Thickness (Temperature Insulation, Transparency), Stretchiness
Shoes	Material
Food	Firmness
Cosmetics	Greasiness, Moistness
Accessories	Weight
Quilts	Texture, Weight
Leather products	Texture, Thickness
Mobiles and accessories	Weight, Firmness

Online Shopping and Touch

During the interviews, participants were explicitly asked to expound on their feelings to the inability to touch in an online shopping context. Participants in this study expressed that when they are not able to touch products – in particular clothes - before buying them they experience feelings of insecurity, uncertainty, doubt, frustration, fear, and risk. These feelings arise from: (1) uncertainty of whether or not the product will be what they expect to be because touch is principally their way to evaluate the quality of the garment; (2) if the product will not fit well because there is no uniformity in the sizes, even if they are buying from a brand they frequently purchase; (3) if it will be comfortable because, as they mentioned, through touch they evaluate if a garment is itchy or not and that is one basic characteristic to evaluate comfort.

Uncertainty...I do not like the idea of not touching or seeing physically what I am buying. (Elean, age 23)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Insecurity...sometimes they tell you the material but as I really do not know a lot about the types of materials or fabrics and I do not know what they are talking about. (Cynthia, age 25)

Despair...fear, distrust... (Sarai, age 22)

Furthermore, participants were asked whether or not touch could be simulated or compensated in an online environment. Although they recognize it is not the same experience, all of the participants answered affirmatively and the stimuli mentioned to provide them information of touch are classified in this paper as: written descriptions and two dimensional images (2D images). On one hand, written descriptions that provide tactile information to consumers include information about fabrics and texture of the product. This information can be provided either by the company or by online reviews of people who have already bought the product and provide written information about the product's tactile characteristics or sensation when touching it. In general, participants mentioned that written descriptions that include this type of information help them to get an idea of the texture and, consequently, to evaluate the possible comfort of the product. However, this was not true for all participants as it was noticed that those who buy online showed more knowledge about fabrics and most of them said that descriptions about fabrics do help them to imagine how the garment feels; yet, those who do not buy online expressed less knowledge about fabrics and how that type of fabric might feel.

On the other hand, it was observed that participants mentioned that 2D images such as photos, including pictures from different angles and zooms, along with videos can provide them with more information about tactile characteristics of the product than written descriptions. For example, 2D images can provide information such as weight, temperature insulation, type of material, itchiness, and softness/smoothness (see Table 3).

If they (written descriptions) describe the type of fabric and you have the experience of touching that type of fabric, then you can imagine how does it feels. (Naila, age 24)

I would like that for us that do not know much about fabrics...to have a description of how does it feels. (Cynthia, age 25)

Through sight… but it is not as effective as touch. (Gaby, age 21)

Through descriptions, pictures from different angles...and the video of how does it (garment) moves, but it is different the experience. (Naila, age 24)

Through images...I think that from all those years seeing types of fabric you can more or less recognize the type of material, it is more difficult but you can have an idea of the material's texture...now technology provides the capacity to see texture. (Elean, age 23)

According to participants, pictures from different angles with a model wearing the garment help them imagine how it could look on them and also to obtain an idea of the dimensions of the product and if it will fit them well, which helps to compensate for the fact that they are not able to try on the product. Additionally, participants mentioned that it is important for the 2D image to convey information about movement of the product, because that helps them to evaluate product's weight; interestingly, this

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

information is not only obtained through videos, but also through pictures. For example, if the product looks somewhat folded simulating movement they perceive it to be lightweight.

Although, not all participants agreed, it was interesting that some of them suggest that a zoom in photo, showing a close up of the product's fabric, could provide information that otherwise would only be obtained by touching the product because of the way the seams looked in the photo. For example, open seams make some participants think that the product will make them feel fresh. Also, through 2D images participants can obtain information about the product's thickness, which also helps them to assess the product's temperature insulation and transparency. Other participants note that products with closed seams are soft and smooth and those with open seams -such as lace- might feel itchy.

I really like zooms…I can see better the material and it is like if I am actually feeling it. (Cynthia, age 25)

You can have an idea if the garment will be fresh or not depending on how close or open is the fabric. (Pamela, age 25)

Table 3. Tactile information provided by characteristics of written descriptions and 2D images

Stimulus	Characteristics	Tactile Information
Written Descriptions	• Type of material • Description of sensation	• Texture
2D images	• Different angles • Movement • Zoom	• Weight • Thickness (Temperature insulation, Transparency) • Material • Texture (smoothness, softness, itchiness)

Finally, there were comments that sometimes pictures can provide misleading information because of the manipulations they go through to make the product look better, these manipulations –according to some of the participants- make it difficult to obtain tactile information. On the other hand, almost all participants found videos more trustful than other techniques in providing tactile information because they perceive them as more realistic and difficult to modify than, for example, pictures.

It is more difficult for it (video) to be misleading, it is more realistic… (Ana Rosa, age 25)

DISCUSSION

There is a considerable amount of research concerning the influence of touch on consumers. As discussed earlier, the use of the Internet platforms for commercial purposes (e-commerce) has brought some challenges for companies that want to sell their products online. Specifically, the lack of opportunity for consumers to physically experience products through haptic explorations can make them become insecure and frustrated and forgo non-touch shopping environments (Peck & Childers, 2003b). This is supported in the findings from this research, which is also in line with the findings of previous studies, consumers experience feelings of insecurity and frustration when they are not able to touch products (Peck & Childers,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2003a). In particular, women in this study mentioned the lack of touch is an important disadvantage of e-commerce, and they also expressed feelings of frustration and uncertainty that makes them –in some cases- avoid purchasing online. However, the current research also revealed women will seek to obtain information about tactile characteristics of products in other ways when touch is not available.

Based on the results of this research, a new concept is introduced: tactile sensation confirmation. Tactile sensation confirmation is defined as when a person imagines an object's sensation (e.g. when the product is in the apparel or in a picture) and after touching that object the person corroborates that the object feels as he/she had previously imagined. As findings from this study suggest, some women tended not to have confidence in their perceptions of how a product feels when they cannot touch the product (e.g. online context). However, consumer's prior experiences of sensation confirmation could play an important role in the confidence of the evaluations of a product's tactile characteristics when touch is unavailable. For instance, due to the skills obtained from previous experiences of sensation confirmation, (i.e. if a person finds that his/her perceptions of how an object might feel are confirmed in most cases), a person could have a greater degree of confidence in the evaluations about tactile characteristics even when not touching the product. This could explain the fact that those who buy products online showed more confidence in their judgments than those who do not buy online. More specifically, those who purchased a garment online expressed that their prior-to-touch perceptions of the sensation of this product category generally remain the same after touching it. In contrast, perceptions of a garment's sensation were generally not confirmed after touching the product for those who had never purchased online. Therefore, previous experiences of sensation confirmation could influence the decision to use Internet platforms to make purchases.

Also, the majority of participants who had never bought online expressed that they touch products for pleasure, whereas the majority of those who buy online use touch just to obtain information. Knowledge of fabric sensation could explain why, as found in this research, people who buy online seem to have more knowledge about the fabrics than those who do not buy online. When touch is not available, those who bought online showed more confidence in tactile information obtained through sight than those who have never bought online.

Consistent with previous literature that suggests touch is a direct form of evaluation of a product and can influence purchase intentions (Peck & Childers, 2003a; Peck & Wiggins, 2006; Peck & Childers, 2006), findings from this research provide evidence of the importance of touch to evaluate products. In particular, this research found that the characteristics of products that are evaluated through touch are texture, thickness, weight, stretchiness, material, firmness, greasiness, and moistness. These characteristics help consumers to assess product's quality, comfort, and durability and influencing the purchase decision.

More importantly, consistent with the "visual preview model" (which states that vision can provide a quick glance of an object that may result in broad but coarse information about the haptic properties of that object) and with the attribution theory (which states that consumers make causal inferences about the quality and performance of a product based on intrinsic and extrinsic cues and that certain cues may influence the evaluation of others) (Klatzy, Lederman, & Matula, 1993; Folkes, 1988); findings from this research suggest that consumers base their evaluations on intrinsic cues such as appearance when evaluating another intrinsic cue such as texture. The women interviewed responded affirmatively to the question of whether or not it is possible to obtain information about the tactile characteristics of a product in an online shopping environment. Specifically, they get this information from written descriptions –either provided by the company or from reviews of other people who have already bought the garment- but also through 2D images.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

On one hand, consumers obtain information about the haptic properties of products through written descriptions, especially those that include information about the type of material and description of sensation; this information helps people to imagine a product's texture. On the other hand, tactile information of products can be obtained through 2D images such as photos, including those that present the product from different angles or zoom in for a close up of product details, as well as videos. As found in this research, 2D images help to perceive product's weight, thickness, type of material, and texture, especially in clothing, through the appearance of movement and zooms to the product. Although, there is a concern regarding the manipulations that can be done to pictures and that could influence consumers to make wrong perceptions about the tactile characteristics of the products. In general, findings from this research suggest that the more realistic the 2D image looks like, the more trust they have in what they see and the tactile information the photos are able to convey. Finally, findings suggest that 2D images where considered as most effective to obtain tactile information than written descriptions.

CONCLUSIONS AND FUTURE RESEARCH DIRECTIONS

As found in this research, it is possible for consumers to obtain tactile information from 2D images and written descriptions. And while 2D images were found to be more helpful for this task, most online stores provide written descriptions with information regarding the type of material of the product, yet almost none include text describing the sensation of the product. Companies using e-commerce as a sales channel should consider describing in a deeper way the sensorial characteristics of a product to help consumers get a better idea of a product.

The concept introduced in this chapter -sensation confirmation- could be influenced by previous experience with similar products. It could be interesting to explore how some people become more skilled in perceiving and imagining the correct tactile sensation of an object than others, as previous sensation confirmation can affect confidence in evaluations. Also, future research could address the role of sensation confirmation in a person's decision to purchase online.

Researchers in the area of image processing and companies using e-commerce should consider finding ways to enhance the richness of 2D images in order to convey tactile information. Additionally, research regarding the use of 3D images and consumer's perceptions of tactile information through these images could contribute both to the literature and to practice. Perhaps more online stores could benefit from the integration of 3D images, as product presentation formats could somehow compensate for consumers' inability to touch in this environment.

Furthermore, the present research provides insights about the tactile characteristics evaluated by consumers for different product categories. Findings from this work could be used as a basis for future research in the area of intelligent techniques. Particularly, researchers could focus on the development of techniques (e.g. recommender) that can assist consumers on the evaluation of tactile characteristics of products when shopping online. For instance, a consumer shopping online could evaluate a product's tactile characteristics prior purchase based on the 2D images and written descriptions available for that product, later when the product is received they could evaluate it again based on real touch to determine whether their perceptions of tactile sensation where confirmed. An algorithm could learn from previous purchase experiences and develop accurate recommendations for new products being considered for purchase might feel.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Finally, because of the nature of this exploratory study, generalizations cannot be made. Future research could study this issue considering other types of product categories, using other methodologies, and including participants from different segments (e.g. men, older people). However, the findings of the present research contribute both theoretically and managerially, as previously discussed.

ACKNOWLEDGMENT

The author would like to thank Consejo Nacional de Ciencia y Tecnología (CONACYT) for the support in the development of this research, through the Grant No. 322346.

KEY TERMS AND DEFINITIONS

E-Commerce: The exchange of information, products, and services through online platforms.

Haptics: Interaction through touch.

Need for Touch: A person's preference for information that is obtained through touching objects.

Product Evaluations: A person's perceptions of the characteristics of a product.

Product Presentation Format: Tool that can be either written descriptions or 2D images with the purpose of providing information of a product to consumers.

Tactile Sensation Confirmation: When a person imagines an object's sensation and this sensation is confirmed after touch.

Two Dimensional Images: Graphics, pictures, or videos that present objects in a flat manner (length and width).

Virtual Touch: Touch sensation that consumers perceive when exposed to a 3D format of a product through a computer.

Chapter 36
Exploring the Role of E-Servicescape Dimensions on Customer Online Shopping: A Stimulus-Organism-Response Paradigm

Rohit Yadav
Faculty of Management Studies, Amity School of Business, Amity University, Noida, India

Tripti Mahara
Institute of Management, Christ University, Bengaluru, India

ABSTRACT

With limited empirical evidence and an incomplete understanding of e-servicescape environment, its effects on e-commerce websites still needs to be explored. Hence, the study understands and assesses the effects of e-servicescape environment on customer purchase behavior, considering the moderating role of gender. The stimulus-organism-response framework was adapted to formulate a conceptual model, in which the e-servicescape (stimulus) features were modelled as an antecedent of customer trust (organism) on website that directs customer behaviour of purchase intention (response). To conduct an analysis, a data sample of 304 responses was collected from those who have earlier used e-commerce websites using a structural equation modelling technique. Results of the study shows that e-servicescape dimensions are a strong predictor of trust that strongly impacts customer purchase intention. Results further reveal that in an online environment, the gender gap is depleting as it impacts all three dimensions of the e-servicescape on customer behavior which remains consistent for both groups.

1. INTRODUCTION

As e-commerce rises, the retail landscape has been revamped for customer and retailer. Customer is presented with superior shopping experience and tailored offers, whereas a retailer is given better opportunities to reach and interact with customers. Additionally, growth of e-commerce is found more

rampant in budding markets as compared to developed countries due to increasing diffusion of information technology, varying customer lifestyle, and increasing customer internet experience (Narang & Trivedi, 2016). Studies demonstrate that e-commerce is growing at a fast pace because of unparalleled growth in number of online retailers and sales. As per statistics of 2018, total internet users in India accounted to 483 million (Statista, 2019). By 2019, this figure of internet users is anticipated to rise by 627 million (Kantar IMRB, 2019). Despite its untapped potential, India already stands as second largest online market worldwide, while China grasps at first position. Bearing this in mind, e-retailers attention has moved towards customers' adoption of online sales channel like e-commerce and further motivating their purchases online. In an experts discussion taken place in Third Annual E-commerce Money Africa Confex in 2017- retailers, academicians and other e-commerce stakeholders discussed on how designs of websites must be centered towards developing economies to offer gripping online experience to surge online purchase (Fastmoving, 2017).

To increase knowledge of possible explanations towards role of e-servicescape dimensions and their holistic effect on purchase intention, a study by (Wu, Quyen, & Rivas, 2017) stated that gender plays a crucial role of moderator in online purchase experience. Furthermore, prior research suggests the assessment of gender differences in online service environments towards their purchase behavior (Cambra-Fierro, Melero-Polo, & Javier Sese, 2016; Hammedi, Kandampully, Zhang, & Bouquiaux, 2015; Ruane & Wallace, 2013). Role of gender has been examined and nested with numerous viewpoints like website design and its usefulness (Cyr & Bonanni, 2005), risk in online shopping (Garbarino & Strahilevitz, 2004; Hong, 2015) and online shopping behavior (Pascual-Miguel, Agudo-Peregrina, & Chaparro-Peláez, 2015). In e-commerce studies context, effect of e-servicescape dimensions on gender difference are at an early stage (Verbraken, Goethals, Verbeke, & Baesens, 2014; Zhang, Lu, Gupta, & Zhao, 2014). Therefore, considering the lack of understanding with respect to moderating role of gender for servicescape environment, this study analyses the influence of different gender (male and female) on the relationship between key e-servicescape dimensions and website trust towards purchase intentions.

In spite of many calls for empirical studies in the field of e-commerce development for developing economies, exploration and investigation in this region remains scarce (Ahmed & Akhlaq, 2015; Kshetri, 2007). The existing models to assess technology adoption like Technology Acceptance Model (TAM) (Venkatesh & Davis, 2000), UTAUT (Venkatesh, Morris, Davis, & Davis, 2003) etc. provides insights towards e-commerce acceptance in developing economies, but they offer restricted knowledge about formation of trust among customers by efficient website design and its final resultant i.e. purchase intentions (Yadav & Mahara, 2017). Therefore, current study puts forward a notion that the above discussed method (e-servicescape dimensions, trust, and purchase intentions) is all sequential in process and stimulus-organism-response (SOR) framework will help in better understanding of the relations. SOR framework is regarded as more inclusive in elucidation of cognitive and affective situations extracted from customers and their following behavior from interaction with online shopping environment or e-servicescape (Tran & Strutton, 2019; Buxbaum, 2016; Vieira, 2013). Yet, empirical evidence lacks on usage of SOR framework towards conception of trust through e-servicescape dimensions and following purchase intentions on e-commerce websites in developing economies. Subsequently, developing economies differ drastically from developed economies; this warrants review of concepts and customs applied on developing economies that conceptualized in developed economies (Sheth, 2011).

On the basis of aforementioned issues, the current study proposes various objectives and a model to advance purchase intentions from e-commerce websites in developing economies by exercising SOR framework. This study forwards various offerings to academicians, practitioners, government policy

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

makers, and non-governmental organizations. First amongst them is application of SOR framework towards creation of purchase intentions from e-commerce websites in developing economies. To achieve this objective, the insertion of various constructs into SOR framework components is proposed to create a reliable and effective conceptual model. The constructs of e-servicescape or online atmospherics includes aesthetic appeal, layout and functionality and financial security (stimulus) with website trust or simply trust (organism) and purchase intention (response). Secondly, aesthetic appeal, financial security and layout and functionality can be controlled through effective website design (Flavián & Gurrea, 2007) and its effect on website trust is examined as it subsequently leads to effect on online purchase intentions (Flavián & Gurrea, 2007; Lim, Heng, Ng, & Cheah, 2016). Thirdly, next objective of the study is to assess the sequential nature of proposed model rooted within SOR framework. Different indirect relations/effects are tested through conducting mediation analyses. According to SOR framework organism mediates the effect of stimulus variable/s on response/s (Mehrabian and Russell, 1974). The core proposal to the theory is that the development of trust begins with the entry of e-servicescape stimulus, trailed by the process of trust organism, with end result of purchase response. Furthermore, the stimulus of e-servicescape can be précised using by e-servicescape attributes. With increased usage of e-commerce, it has become an integral part of our daily lives, the scarcity of related e-servicescape research pushes us to probe further into e-servicescape, and how this mix, in combination with trust in e-commerce, affects customers' purchase intention. Lastly, this model is assessed to observe how results varies towards one key variable i.e. gender and its influence on customer purchase decisions (Fang, Wen, George, & Prybutok, 2016; Lian & Yen, 2014; Yoon & Occeña, 2015). As a resultant, this study not only provides value addition in theory to various stakeholders' knowledge towards application of SOR framework in developing economies but also makes available a parsimonious model to enable surge in online purchases from their e-commerce websites. This is achieved via persuasive online experiences and effective website design varied by gender experience.

The organization of the paper is as follows. Section 2makes available theoretical framework for the study that helps to formulate hypotheses in Section 3. Thereafter, research methodology provides various research methods applied in this study that later helps in analysis of the results. Later, results are discussed and study concludes with its contributions, limitations and scope for future research.

2. THEORETICAL FRAMEWORK

This study aims to develop e-servicescape model to explore consumers' understanding of e-servicescape and its effect on consequent assessment of website trust and behavioral purchase intention with the help of Stimulus-Organism-Response (SOR) framework for Indian online shoppers as depicted in Figure 1. We will also assess gender differences as a moderating factor in relationships amongst e-servicescape dimensions and trust.

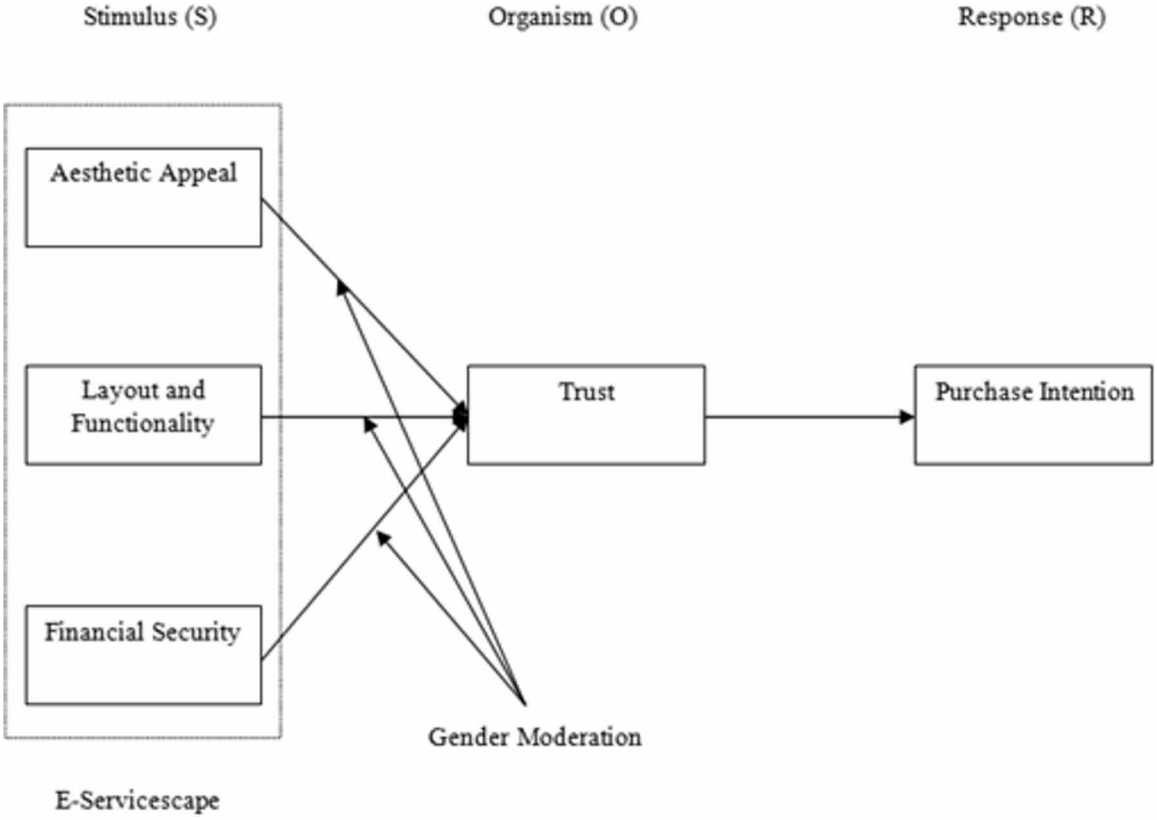
2.1 Stimulus-Organism-Response Framework

In Stimulus-Organism-Response model, Stimuli (S) are external to an individual and they compose of different physical atmospheric factors (Bagozzi, 1986) that influence individual's behavior (Eroglu, Machleit, & Davis, 2003). In an online environment, it provides set of website dimensions that are influential in surging customer intention (Mollen & Wilson, 2010). Hence, current study uses e-servicescape

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

dimensions namely: Aesthetic appeal (Wang et al. 2011), Online layout & functionality (Wu et al., 2017) and Financial security (Harris & Goode, 2010); (Kim & Lennon, 2013) to be stimulus. Study argues that these dimensions creates a specific environment (Huang, Li, Mou, & Liu, 2017) that significantly effects customer purchase intention to shop on e-commerce websites.

Figure 1. Research model



Aesthetic appeal is website's complete visual impression and attraction. It is a tool for a website to differentiate itself from competitors and hence is considered key factor for e-retailers (Harris & Goode, 2010). Online layout and functionality are design aspects of a website that generates pleasurable interactions and user experiences. Online layout is defined as overall arrangement, adaptability, structure and organization of any website (Wu, Lee, Fu, & Wang, 2013) whereas functionality is the contents of a website (Law & Hsu,2005). Financial security in the online domain is the degree to which a customer believes that their personal or financial information will remain safe and not be stolen or shown, saved by unwanted parties through e-commerce purchase process (Azizi & Javidani, 2010; Flavián & Guinalíu, 2006). Efficiency and effectiveness of all these features hold website usability. Consequently, website usability aids in clarification of significant information and improves communication. At the same time, it enables a consumer to seek information in an easy manner.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Organism (O) is defined as internal structures and processes that mediate amid external stimuli to individual and their final response (R) (Bagozzi, 1986). The organism is the cognitive and affective agent that mediates stimuli and responses of customers (Kim & Lennon, 2013). Here, cognitive agent represents customers' mental processes that comprise of customer thoughts towards acquisition, processes, retentions and retrieval of information (Eroglu, Machleit, & Davis, 2001; Fiore & Kim, 2007). On encounter with a stimulus, customer processes it into meaningful and useful information towards their final decision (Huang et al., 2017). Organism in current study is operationalized as trust (Lunardo & Mbengue, 2013; Rahul & Aggarwal, 2017) as consumer behavior studies advocate the importance of trust on website and its services while shopping online (Agag & El-Masry, 2016). (Kim, Ferrin, & Rao, 2009) define trust as the point of reliability and credibility on new technology by people. In context of this study, trust is defined as consumer's confidence towards the website and willingness to trust the sellers' actions in situation where customers may otherwise be vulnerable.

Response refers to a customer's outcome behavior of an approach and avoidance (Donovan & John, 1982). While, approach refers to positive response shown by customer during specific settings as purchase behavior and affirmative communication, avoidance is shown through negative communication and rejection intentions (Eroglu et al., 2001). According to previous studies, response is the final customer outcome like behavioral intentions (Brunner-Sperdin, Scholl-Grissemann, & Stokburger-Sauer, 2014) and purchase (Kim & Lennon, 2013). Therefore, this study assesses response via customers' purchase intention.

3. HYPOTHESES DEVELOPMENT

3.1 Aesthetic Appeal with Trust

According to a study by Harris & Goode (2010), online aesthetic is an online ambience form i.e. degree of attractiveness or appeal of beauty felt by consumers towards e-servicescape. In further addition, Wang, Minor, & Wei (2011) referred to web aesthetics as e-servicescape cues yielding an impression of attractiveness or beauty. This view is in concordant with various studies that suggest that the nature, size, website presentation and online images are crucial considerations (e.g. (Shobeiri, Laroche, & Mazaheri, 2013)). (Donnelly, 2001) stated that customer evaluates website on individualized information needs and therefore it must be tailored accordingly. Hence, it is obvious that a consumer wishes to enjoy aesthetic design of the service place and hence results in higher pleasantness effect (Loureiro & Sarmento, 2014; Wang et al., 2011). Customer satisfaction rises in an online interaction environment if it occurs in a more pleasant aesthetic e-servicescape. Such insights lead Hasan (2016); Seckler, Heinz, Forde, Tuch, & Opwis (2015) to conclude that a wide range of website visual characteristics affects users behaviour and argue that marketers and retailers must consider effects of website aesthetics. Thus, study assesses aesthetic appeal on attractiveness and beauty, entertaining and exciting referred from (Harris & Goode, 2010; Loureiro & Sarmento, 2014; Wang et al., 2011). This is strongly supported by recent empirical results that strongly links aspects of website aesthetic appeal (navigation, images, links and searches) to website trust (Kim, Chung, & Lee, 2011). (Al-Debei, Akroush, & Ashouri, 2015; Michaud Trevinal & Stenger, 2014) suggested that the website visual experience exerts a strong influence on continued usage. These findings have led researchers to argue implications of trust in online shopping experience and its association with aesthetic appeal of the e-service environment like (Teng, Ni, & Chen, 2018). Thus, we propose:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H1. Aesthetic appeal has positive influence on trust.

3.2 Layout and Functionality with Trust

Manganari, Siomkos, Rigopoulou, & Vrechopoulos (2011) identified in his study that layout is a key factor to influence consumer decision making process. Hooper, Coughlan, & Mullen (2013) suggest that functionality and usability of a website are chief dimensions for consumer's evaluation of online environment. Manganari, Siomkos, Rigopoulou, & Vrechopoulos (2011) identified that online layout of websites are built on the basis of customer pleasure, that engages customer in further participation. Various studies have put forward suggestions and recommendations on website design, its effectiveness and also customer evaluations (e.g. Bai, Law, & Wen, 2008; Fu Tsang, Lai, & Law, 2010). Bai et al. (2008) defined functionality as consumers' usability of website interface and the navigations. Law and Hsu (2005) conducted measurement of online functionality through a verified measurement scale that consist of purchase information, product/service information, contact information, destination information and quality of information. A range of studies suggests that websites must provide effective base services and also help improve service experience (e.g. (Venkatesh, Chan, & Thong, 2012; Yeo, Goh, & Rezaei, 2017)). Recently, theorists have focussed on potential risks of erroneous website personalization (Frels & Kannan, 2001) and therefore suggested that negative usage behavior can be avoided by a cautious personalization approach (see (Kannan, 2016)), and this will yield more trust over continuous usage of website.

This study assessed online layout and functionality on content/information, navigation features and their usage easiness as referred from Montoya-weiss, Voss, & Grewal (2003); Srinivasan et al. (2002); Zeithaml, Parasuraman, & Malhotra (2002). According to Srinivasan et al. (2002) most crucial aspect of customer evaluation of a web site is its ease in usage/navigation usability. Also, various studies states that relevant information is crucial to website usage (Bauer, Grether, & Leach, 2002; Zeithaml et al., 2002). Similarly, Montoya-weiss et al. (2003) states that content information forms a key variable to consumer's assessment of a website services. Therefore, we propose that:

H2. Layout and functionality have a positive influence on trust.

3.3 Financial Security with Trust

Security in online shopping websites is considered a big concern as its abuse or failure can cause conditions of economic hardship through disclosure, destruction, alteration of data, service denial and/or fraud etc (Roca, García, & Vega, 2009). Tsang et al.(2010) suggests that online financial security and payment procedures are a key to ultimate purchase decision. As most consumers are unaware with usage of their personal and financial information given on e-commerce websites, therefore it is considered as one of the biggest barriers to e-commerce adoption and its growth (Shah, Peikari, & Yasin, 2014). With rising attacks on online information of customers, frauds and system vulnerabilities, consumers are getting more hesitant providing sensitive information to shopping websites (Tsang et al., 2010; Yenisey, Ozok, & Salvendy, 2005). In this sense, focussing on the key role of trust in online trade and exchange, studies have stressed on the significance of financial security in websites (e.g. (Barkhordari, Nourollah, Mashayekhi, Mashayekhi, & Ahangar, 2017; Bonsón Ponte, Carvajal-Trujillo, & Escobar-Rodríguez, 2015; Hartono, Holsapple, Kim, Na, & Simpson, 2014; Shah et al., 2014)). Thus, we propose:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H3. Financial security has a positive influence on trust.

3.4 Trust with Purchase Intention

Every individual has different trust and belief patterns over others. These characteristic shows an impact upon customers' trust in e-commerce as well (Brengman & Karimov, 2012). (Casaló, Flavián, & Guinalíu, 2010; Ruiz-Mafe, Martí-Parreño, & Sanz-Blas, 2014) held that trust can lower down uncertainties regarding the future outcomes and is essential for a continued relationship for product or service of customer needs. Trust on online environment portrays inclination of an individual towards its services and processes. Online purchase requires trust to be imbedded not only between customer and retailer, but also amongst customer and the computer system built to carry out transactions. Studies have been conducted to assess trust in e-retail stores and verified it as a vital antecedent to drive purchase behaviour (Brengman & Karimov, 2012; Casaló et al., 2010; Ruiz-Mafe et al., 2014). Trustworthy website environment is crucial towards generating e-commerce success and surge consumer activities (Kim & Prabhakar, 2000). In short, trust on a websites includes customers beliefs and expectations about online merchants and their services (Casaló et al., 2010; Curras-perez, Ruiz-mafe, & Sanz-blas, 2014). To summarize, customer's general trusting nature plays a key role in determining their online purchase behavior. Consequently, the following hypothesis is constructed:

H4. Trust has a positive influence on purchase intention.

3.5 Mediating Role of Organism Component: Trust

This study assesses purchase intentions for e-commerce websites in developing economies by application of SOR framework. Additionally, study assesses effect of organism factor from SOR framework on cognitive and affective conditions consequently due to their contact with environmental cues i.e. Stimulus factors, that subsequently has effects on response factor (Loureiro & Ribeiro, 2011). As a result, organism factor/s (i.e. trust) act as mediating link between the other two components of SOR framework i.e. stimulus and response (Vieira, 2013). Plentiful studies have approved on mediating role of trust in identifying purchase intentions of customers through e-commerce websites (Ha, John, John, & Chung, 2016; Hong & Cha, 2013; Lwin, Wirtz, & Stanaland, 2016). Hence, these hypotheses are proposed:

H5: Aesthetic appeal has a positive indirect effect on purchase intentions through mediating trust.
H6: Layout and functionality has a positive indirect effect on purchase intentions through mediating trust.
H7: Financial Security has a positive indirect effect on purchase intentions through mediating trust.

3.6 Gender Moderation

Numerous studies under marketing domain have studied gender and its role, but only few have assessed relationship between gender and e-commerce (Ladhari & Leclerc, 2013; Rodgers & Harris, 2003). Available e-commerce related studies show that there exist significant differences amongst both genders. Their choices drives them towards adoption behavior and further usage (Lin, Featherman, Brooks, & Hajli, 2018; Venkatesh, Morris, & Ackerman, 2000). Results of gender moderation in online environment are not similar across all studies. One research dimension discusses and approves of gender dif-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ferences across online environment usage behavior and it moderates usage and adoption behavior (Lim & Kwon, 2010; Lin et al., 2018; Liu, Li, Zhang, & Huang, 2017; Lu & Lee, 2010). On the other hand, a different research stream suggests that gender gap amongst usage of online environment is depleting as both male and female believe that key functions are equally important (Nadeem, Andreini, Salo, & Laukkanen, 2015; Zha, Zhang, Yan, & Xiao, 2014). Similarly, many studies confirmed that both have similar taste towards online shopping preferences like Ladhari & Leclerc (2013) found no significant difference amongst both genders during examination of websites and e-tailers receptiveness. Study by Zha, Zhang, Yan, & Xiao (2014) also showed no significant differences amongst both genders in online environment contexts. Likewise, study by Liu, Li, Zhang, & Huang (2017) demonstrated no significant difference in both genders on customer perception and expectation of online environment. Even study by Nadeem, Andreini, Salo, & Laukkanen (2015) stated that online environment usage and perception gap by both genders is declining. Therefore, this study attempts to address this inconsistency by assessing gender moderation effects on online retailer websites e-servicescape dimensions towards purchase intentions. Considering past research findings and their emphasis, study proposes three hypotheses:

H8. The effect of both the genders will remain same amongst aesthetic appeal and trust relationship.
H9. The effect of both the genders will remain same amongst layout & functionality and trust relationship.
H10. The effect of both the genders will remain same amongst financial security and trust relationship.

4. METHODOLOGY

This study utilized snowball technique (Coleman, 1958). This technique is a chain referral sampling method that uses convenience sampling of participants; the sample group grows through a network like a rolling snowball. This methodology is usually used for market research (Campbell & Wright, 2008). In this method, initially few respondents were approached and they were later asked to suggest other respondents who are willing to contribute and this process goes on subsequently. Participants voluntarily replied to questionnaire without any incentives in return. Suitable measures were utilized to ensure diverse demographic data of respondents is gathered. Furthermore, there are similar studies (Kurasaki, 2000) in the extant literature employing snowball sampling in a survey (Yadav & Rahman, 2017). To collect data, study aimed at retail customers with their previous experience of e-commerce website and its services towards browsing or purchase.

4.1 Sample

Questionnaire based study is adopted. Survey is designed in a structured and non-disguised manner where respondents were clearly told purpose of the survey and gained their consent with information. 5 variables (aesthetic appeal, financial security, layout and functionality, trust and purchase intention) with 21 items were included in survey apart than general demographic questions. Variables were measured on a 5-point Likert scale, except demography related questions. Each measure was drawn from earlier studies and was adapted for current research. For questionnaire refer to Table 2.

By application of snowball sampling, 1000 people were mailed the questionnaire and 306 replied back. Out of these 306 only 304 were considered usable, which comprises of 144 females and 160 males. Similar sample sizes have been taken in various studies and considered a fit (Kaushik & Rahman, 2015;

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Yadav & Mahara, 2018). Demography of respondents is briefed in Table 1. Sample demographics collected in this study is considered fit in similar studies like Alalwan (2018), conducted for social media habits. This kind of research majorly includes youth sample of age group 20-30 years. Major chunk of respodents are young and students who are ready to share their information easily. Demographics details shows that snoball method works well with young people as they are more networked and it also represents national data fit.

4.2 Measures

The items used to assess e-servicescape and trust items used in this study are taken from Harris & Goode (2010). Aesthetic appeal composes of four items, with sub dimensions as: visual appeal (two items), Originality of design (one item) and entertainment value (one item). Layout and functionality (four items) measured through sub-dimensions: information relevance (one item) and usability (three items). Financial security comprised of four items with sub dimensions: Ease of payment (two items) and perceived security (two items). Trust composed of 4 items taken directly from Harris & Goode (2010). Purchase intention was adapted from (Gao & Bai, 2014) with one item from (Yadav & Mahara, 2017).

As this study includes voluntary participation to fill questionnaire and further respondents' recommendation without any incentives in return, therefore questionnaire length fit was ensured to not overexert participants. Many items were removed initially due to reliability and validity issues. Later, total length of the questionnaire from Harris & Goode (2010) was perceived too long to get proper responses from respondents and avoid unit non-response biasness, therefore it was shortened up by removing most crosscheck items and few items that were not found fit for Indian consumers. This aided in better understanding of the questions asked.

Study used Armstrong & Overton (1977) to diagnose unit non-response biasness, through a comparison of "initial" and "delayed" participants based upon their response date. Non-response bias was assessed using t-test that compared sample means of initial 30 percent of the participants with delayed 30 percent participants. Results demonstrated no significant differences exist amongst the two sets, signifying no issue of unit non-response biasness with respondents' data.

In this approach of data collection, we avoided item non-response bias by providing help to the respondents for filling the form and avoided unit non-response bias by approaching people who are willing to take part in the survey. These two approaches worked well to gain good responses.

5. ANALYSIS

5.1 Preliminary Tests

Table 2 depicts the results of exploratory factor analysis. Items with poor loadings (loadings < 0.50) were removed from analysis. Remaining 18 items were assessed using principal component analysis (PCA) and resulted in 5 factors (Eigen values>1) which accounted for 71% variance. Reliability scores of all factors were found acceptable from 0.77to 0.87.

Complete latent model was created using results of exploratory factor analysis and tested with the help of SPSS AMOS to know relational as well as measurement properties of the model. Acceptable relative, comparative and absolute model fit indices were ensured using Bentler (1992). 5 factor structures

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

were confirmed by first order confirmatory factor analysis (CFA). Indices resulted in good model fit to data. Convergent validity was confirmed by average variance extracted (AVE) (AVE ≥ 0.50) for all the factors individually. AVE varies from 0.57 to 0.61, confirms convergent validity. Further confirmation of convergent validity was given by path analysis through structural equation modelling (SEM) and all path coefficients were found statistically significant. Discriminant validity is confirmed if AVE is greater than the squared correlation coefficient between factors, which was true for all the factor pairs (Fornell & Larcker, 1981).

Table 1. Respondents demography

Measure	Item	Frequency	Percentage (%)
Total		304	100
Gender	Male	160	52.6
	Female	144	47.4
Age	Below 20	57	18.8
	20-30	157	51.7
	31-40	63	20.7
	Over 40	27	8.8
Occupation	Student	173	56.9
	Free Lancer	22	7.2
	Entrepreneur	33	10.8
	Employee	61	20.1
	Retired	15	5

5.2 Structural Model Test

SEM was used to test causal relations amongst variables for the proposed model for complete data (N=304). Joreskog and Sorbom (1993) suggests GFI and NFI acceptable values to be less than 0.9; Hu & Bentler (1999) suggests CFI value to be <0.95; Bollen & Long (1993) suggests RMSEA values to be less than 0.06. Fit indices of the model were a good fit (χ^2/df = 2.14, RMSEA = 0.04, CFI = 0.950, NFI = 0.935 and GFI = 0.925), similarly assessed by studies (Yadav & Mahara, 2017, 2018). These results gave strong support to the proposed model (Hair, Black, Babin, & Anderson, 2010; Hair, Anderson, Tatham, & William, 1995). Table 3 summarizes path analysis results. Relationships amongst all the causal paths were tested and confirmed. Aesthetic appeal is significantly and positively influenced by trust ($\beta = 0.523$, $p < 0.001$). Financial security is significantly influenced by trust ($\beta = 0.489$, $p < 0.00$); and layout and functionality is significantly influenced by trust ($\beta = 0.322$, $p < 0.00$). Purchase intention is significantly affected by trust ($\beta = 0.532$, $p < 0.00$) and it is the strongest of all relations. These results support hypotheses H1, H2, H3 and H4.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Results of reliability and convergent validity

Items No.	Items	Factor Analysis (PCA)	Cronbach's Alpha	Standardized Factor Loadings (λ)	Composite Reliability	Average Variance Extracted (AVE)
Aesthetic Appeal	I like the way this website looks	0.743	0.862	0.671	0.711	0.582
2	The design of this website is adventurous	0.733		0.628		
3	I think that this website is very entertaining	0.710		0.573		
4	The way this website displays its products is attractive	0.725		0.596		
Layout and Functionality 1	This website is easy to navigate	0.614	0.878	0.605	0.724	0.508
2	There are convenient ways to go among related pages and between different sections	0.754		0.738		
3	Navigation through this website is intuitive	0.815		0.756		
4	Information about products is easily accessed on this website	0.737		0.499		
Financial Security 1	When using this web site, paying for goods does not require a lot of details	0.686	0.773	0.762	0.799	0.571
2	When buying from this website I am confident in the security procedures	0.797		0.806		
3	Overall, this website seems security conscious	0.764		0.753		
Trust 1	This website is genuinely committed to my satisfaction	0.707	0.838	0.590	0.859	0.611
2	If this website makes a claim or promise about its product, it is probably true	0.816		0.927		
3	I feel I know what to expect from this web site	0.818		0.874		
4	I feel that I can trust this web site	0.524		0.695		
Purchase Intention 1	I would like to revisit this website in near future	0.852	0.843	0.826	0.823	0.591
2	I would recommend this website to my friends and others	0.851		0.739		
3	This website will be my first choice over others	0.811		0.699		

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Hypotheses test

Hypotheses				Path Coefficient (β)	Error	t-value	p-value	Test Results
H1	Aesthetic Appeal	→	Trust	0.523	0.053	9.556	***	Supported
H2	Layout and Functionality	→	Trust	0.322	0.044	6.521	***	Supported
H3	Financial Security	→	Trust	0.489	0.045	9.788	***	Supported
H4	Trust	→	Purchase Intention	0.532	0.052	9.822	***	Supported

*** means p-value = 0.000

5.3 Mediating Effect of Organism: Trust

The mediating effect of trust on relationship between e-servicescape dimensions and purchase intentions was tested by use of extensively acknowledged method given by Baron & Kenny (1986). According to this approach, mediating effect of a variable is established once following four conditions are fulfilled.

First, independent variable/s (e-servicescape dimensions) has to significantly affect mediating variable (trust). Second, mediating variable must significantly affect the dependent variables (purchase intention). The two conditions are already fulfilled as shown in Table 3. Third, independent variables (e-servicescape dimensions) must directly influence dependent variable/s (purchase intention). Towards third condition assessment, direct effect of e-servicescape dimensions on purchase intention was assessed. Results shows that aesthetic appeal, layout and functionality and financial security affects trust ($\beta1 = 0.248$, $p < 0.001$; $\beta2 = 0.202$, $p < 0.001$; $\beta3 = 0.255$ $p < 0.001$ respectively). Fourth, path coefficients values of an independent variable/s to its dependent variable/s either reduce its value to prove partial mediation or it converts insignificant showing full mediation when any mediator/s is applied into a model. From Table 4, findings suggests that the path coefficient values for all e-servicescape dimensions to purchase intention were reduced ($\beta1 = 0.113$, $p < 0.001$; $\beta2 = 0.109$, $p < 0.001$; $\beta2 = 0.098$, $p < 0.001$ respectively) but remained statistically significant, therefore partial mediation of organism component i.e. trust was proved.

Table 4. Mediating effect of trust

Independent		Dependent	Direct Effect	Indirect Effect	Mediating Role
H5	Aesthetic Appeal	Purchase Intention	0.248***	0.113***	Partial Mediation
H6	Layout and Functionality	Purchase Intention	0.202***	0.109***	Partial Mediation
H7	Financial Security	Purchase Intention	0.255***	0.098***	Partial Mediation

*** means p-value ≤ 0.001

5.4 Moderating Effect of Gender

To conduct further analysis of hypotheses H8, H9 and H10, study requires usage of advanced multivariate analysis method (Hayes, 2009) by using AMOS 20.0 and multi-group analysis of both genders. (Byrne,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2016) recommended use of structural and measurement constraints to assess model equality and authors methods have been applied by different studies (Yadav & Rangnekar, 2015, 2016) for multiple group analysis. Two models are assessed, females (N=144) and males (N=160). Goodness-of-fit indices for both the models were found significant i.e. male (χ^2/df=1.9, RMSEA= 0.04, CFI= 0.932, NFI = 0.925 and GFI = 0.945) and female models (χ^2/df=2.1, RMSEA= 0.05, CFI=0.926, NFI = 0.905 and GFI = 0.901).All causal paths were found significant in structural path analysis.

Table 5 shows results of moderation for the gender groups i.e. male and females. As results clearly shows that aesthetic appeal has significant and positive relationship with trust for both the genders i.e. male: β= 0.406, t = 4.12; female: β = 0.431, t = 4.22, thus accepting hypotheses H8. Similarly, layout and functionality has a significant and positive relationship with trust for both the genders i.e. male: β= 0.358, t = 3.64; female: β = 0.388, t = 3.91, thus accepting hypotheses H9. And finally, financial security has significant and positive relationship with trust for both the genders i.e. male: β= 0.427, t = 4.35; female: β = 0.489, t = 4.76, thus accepting hypotheses H10. Therefore, there is no moderation amongst both the genders for e-servicescape dimensions and trust on website.

5.5 Execution Time Summary

Table 5. Invariance test across gender

Hypotheses				Standardized beta values (β) (t) (p)		Test Results
				Male	Female	
H8	Aesthetic Appeal	→	Trust	0.406(4.12) ***	0.431(4.22) ***	M=F (Supported)
H9	Layout and Functionality	→	Trust	0.358(3.64) ***	0.388(3.91) ***	M=F (Supported)
H10	Financial Security	→	Trust	0.427(4.35) ***	0.489(4.76) ***	M=F (Supported)

*** means p-value ≤ 0.001

6. DISCUSSIONS AND IMPLICATIONS

6.1 Theoretical Implications

Results of the study authenticate the concept that e-servicescape dimensions lay high effect on customer's website trust, bundled in SOR framework. Findings of the study confirms with past studies stating that customers' website trustworthiness is mostly influenced by e-servicescape dimensions (Tran, Strutton, & Taylor, 2012). Amongst e-servicescape dimensions aesthetic appeal was found to be most influential and significant in relationship with online website trust. Results of the study confirm that individuals are more likely to purchase when they trust a website and its ambience while searching for information online. In this sense, findings of this study support the notion that buyer and seller relationship have trust as most crucial challenge in e-retail studies. These findings related to aesthetics of a website, showcases that aesthetic appeal or visuals of a website are crucial in creation of trust towards online retail customers. Therefore, due consideration must be given to designing user's interface (feel and look) of an e-commerce website. Elements to be included must be pleasing and have appealing graphics, fonts and theme for the website with displayed information and product assortment for browsing customers.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Further results indicate that layout and functionality positively and significantly influences trust over e-commerce website. Considering website trust and relation of layout and functionality, online retailers must decide and design an optimized journey for customers' purchase experience. These findings are crucial and interesting as they recommend that online retailers must concentrate on aesthetic appeal to increase pleasing effects of website and also on its layout and functionality to ensure heightened website easiness and usability is generated towards services. Similarly, financial security is found to be a major influencing factor towards generating trust of customer. Financial security on e-commerce websites is considered a major issue amongst customers (Harris & Goode, 2010), as its abuse or failure can cause distrust for retailer and hardship for customers through disclosure, destruction, alteration of data, service denial and/or fraud etc. Therefore, all e-servicescape dimensions should be strategically culminated to keep customer pleased and comfortable while browsing through different pages and ensure website trust.

Study also assessed the role of organism component (trust) to fulfil a mediating role in determining consumers' purchase intentions from e-commerce websites (Ha et al., 2016; Hsu, Chang, Kuo, & Cheng, 2017; Lwin et al., 2016; Pelet, Ettis, & Cowart, 2017). Results indicate that trust partially mediates the relation between all e-servicescape dimensions and consumers' purchase intentions indirectly, even though differently. Therefore, it can be established that organism component of SOR model truly emphasizes on a persons' cognitive and affective conditions due to their relation with e-servicescape dimensions, that subsequently affects their response i.e. purchase intention (Loureiro & Ribeiro, 2011).

Exploring the role of gender helps retailers, marketers and other stakeholders verify need of gender-based specific strategies for both groups i.e. male and female. Results of gender moderation showed no difference towards services and features, this indicates that gap amongst taste and usability of e-commerce and its services is deteriorating. Findings from this study are in consistency with many latest studies that found no significant differences amongst both genders in the context of e-commerce websites. Like, Ladhari & Leclerc (2013) found no significant difference amongst both genders during examination of websites and e-tailers receptiveness. Therefore, when marketers and other stakeholders discussing e-servicescape dimensions they must keep in mind that all the environmental cues like aesthetics of website and security of services, etc must not be too customized as per gender. Too much emphasis on gender customized website can also result in dislike and distrust by customer leading to loss of customer.

6.2 Managerial Implications

This study endeavours to identify the significance of e-servicescape in the e-commerce context. Results of this study points to key significant implication i.e. e-retailers, website designers, architects of website and other stakeholders must ensure good quality of environmental cues and ensure customer of available safety and security. For consumers, willing to shop online, websites are the most crucial contact point for them to know products and services. As online consumers lack feature of touch or feel during product purchase process, effectiveness of website e-servicescape dimensions becomes more crucial as it ensures comfort required for peace of mind. A comfortable, useful and efficient website and its services do not just help create an easy checkout but they also remove customers post-purchase dissonance. To maintain long-term relationship with existing customers, retailers and managers must design website in terms of better e-servicescape features: outlook design, functionality and security which are at par with customer needs. A noteworthy discovery of this research is that aesthetic appeal shows highest significant impact on customer intentions. This implied that a good appearance appeal helps customers cherish e-commerce website and its aesthetics. Hence, website designers, architects and software engineers must emphasize

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

on the visuals of websites and optimize their design effectiveness. Aesthetic appeal can be improved by usage of different colors, entertaining features, sounds and so on. It becomes vital that digital marketers, managers and other people involved are able to elicit positive emotion and preference towards products, their brands and organizations entirely.

Further it can be implied that financial security, layout and functionality are also crucial to customers purchase intentions. Once consumer identifies a website to be of low-quality e-servicescape or finds visually unattractive, not safe towards payment process and has complex/difficult layout and functionality, then consumer will consider website to be of low or no utility to him/her. Such alterations in judgement due to low-quality e-servicescape lead consumers' towards rival websites. Moreover, all these services and design aspects must be integrated into the development process of a website as overall environment or atmosphere experience of a website leads to customers trust and purchase behavior. For example, Alibaba the Chinese e-commerce giant has segregated its payment and financial security services to its subsidiary unit Alipay to provide ease in payments and various other features.

Another implication to this study is that too much customization can formulate a complicated interface for the users. As per (Reibstein, 1999), internet shoppers are mostly composed of males who are young and well educated. But results of the study imply that retailers, marketers and other stakeholders have no need for gender-based e-servicescape environment segmentation. As both the gender groups have similar taste towards website interface and services needed; therefore, websites must avoid gender specific customization. Reason being mediation of technology has depleted gender biased taste and usability gap for e-commerce websites. Consequently, simple and standard website interface with usable services are preferred by customers and also provides an environment of trust and comfort.

7. CONCLUSION

This study is aimed at identifying and assessing a model to surge customer purchase intentions on e-commerce platform in developing economies by applying SOR framework. Concurrently, the application and usefulness of SOR framework to online shopping environment is established through effective website design and other features (e-servicescape), where study proves to be of good value for identifying customer purchase intentions. Study identified that Stimulus (e-servicescape dimensions) creates response (purchase intention) via organism (trust) through a sequential and consistent flow where gender moderation does not show much difference to respondents' likability towards e-servicescape dimensions for an e-commerce website.

8. LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

Although this study helped identify effects of various e-servicescape dimensions for e-commerce platforms, future studies can also explore other relevant constructs of online environments like engagement, customization/personalization effect, interactivity, information effects and security to surge customers' purchase intentions in developing economies. This study used gender as a moderator to understand relations better, still future studies can gain more insights into customer behaviour by introducing other moderating variables like retailer type, type of device, occupation, internet usage, product attributes, etc. Although, study was focused towards developing country and sample was gathered from India, future

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

studies can benefit by identifying cultural differences across different geographical boundaries. Finally, study did not take into account time series data of customer towards their experience with the websites as it has major implications. So, future studies can benefit by conducting time series study on customer behaviour towards e-commerce websites and their services.

9. FUNDING INFORMATION

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

Chapter 37
Experiencing Commercial Videos for Online Shopping:
A Cross-Cultural User's Design Approach

Jose Cañas-Bajo
Aalto University, Finland

Johanna Silvennoinen
University of Jyväskylä, Finland

ABSTRACT

Although online shopping has become a popular and convenient instrument for companies to buy and sell products, the design of these web-shops does not always offer the rich multisensory experiences that physical retailing offers. In the chapter, the authors argue that introducing audio-visual contents in the design could provide dynamic multisensory information to offer more engaging experiences to the consumer. Despite existing controversies regarding universalism of the emotional experiences induced by perceptual processes, the authors present evidence that suggests cultural modulations of videos experiences. Spanish and Finnish participants interacted with audiovisual products depicting videos of a culturally loaded brand design. Content analysis of participants' verbalizations helped to identify categories and subcategories that defined the representation of the video elements and their relative weight depending on the cultural background of the viewer. Although results indicate common elements affecting viewers of the two countries, they differ in the relative weight to global aesthetics features.

INTRODUCTION

For some years now, Internet is considered a useful tool that helps companies to rapidly spread information about their products to very diverse geographical location at a very low cost. Internet use many times reduces the cost for marketing and also permits companies to offer their customers the possibility of buying from home independently of where the product or the company is located. The reduction of the product cost and the possibility of buying from any location make Internet shopping an attractive

instrument for companies and customers. However, displaying the product on internet for online shopping greatly differ from the displays of the product in traditional physical shops where the costumers can not only look at the products from fixed angles, but also move and look at them from different distances and perspectives, touch them and even try them, Hence, internet does not usually offer the rich multimodal experiences than physical shopping offers. For these reason, because online shopping usually display the products in two dimensional surfaces and lacks the richer sensory experiences than the physical shops offer, the design of the online shop needs to take special care of the arrangement of the visual elements, the format of presentation, the combination of colours, etc. Usually the products are introduced by presenting pictures and verbal descriptions of their features, but the designer's job is to try to induce positive impressions and good experiences in the users by distributing the element of the web in particular ways. The choice of colours, sounds, and images seeks to influence the users and induce them to by the product (Childers et al. 2002). Despite these efforts, many aspects of the real shopping environment are missing in the static web displays, and this might introduce communication barriers between companies and customers. One way of reducing these possible problems is to introduce dynamic elements by adding video contents to the online shops. Videos can be useful devices to induce emotions and change consumers' perceptions of an object. The mental representations of a product can be influenced by the emotions attached to the audiovisual contents where the product is inserted (Moran, 1981). By exposing an individual to a video-based content about a product, emotions toward the product can be created, which might lead to a positive tendency to consume it (Wang & Cheong, 2006). However, to ensure that these audio-visual elements induce positive experiential, and informational representations of the products, we need research that helps to provide guidelines for enhancing visual communication with the users. As suggested by Childers, et al. (2002) costumers of online-shops do not only use the web to buy in a more efficient manner, but they also look for entertainment. Adding video contents to the shop web design may introduce this important hedonic dimension by making the presentation of the product richer and more attractive. Videos may provide attractive contexts where to display the products, to enhance their aesthetic features or to describe the quality of their manufactured elements. An aesthetically enhanced video might increase the probability that the consumer buy the product, but also may induce him/her to visit the online shop in the future, and to forward the link to other prospective shoppers (Reinecke & Gajos 2014). Recently, Ecklers and Rogers (2014) also suggested that audio-visual contents form part of the viral phenomena, highlighting the influences that videos might have as strategies for marketing (Purcell 2010).

As we mentioned, however, there is not enough research directed to investigate the impact that different elements have on the consumer experience. In addition, sometimes companies have made ill use of videos by applying emotional sensationalism and try to catch the audience attention through unconventional designs and ideas with the risk of triggering a negative reaction on the potential consumer (Ecklers & Rogers 2014) instead of the desired positive experience. But what element catches attention and interest in the consumers when exploring an online-shop? Interest is an important emotion for online shopping that has been explored in the context of film studies. According to Silvia (2005) interest involves evaluation of the degree to which an idea or event is complex, unexpected and difficult to process, but at the same time is evaluated as possible to cope and to understand. Thus, people find interesting complex or unusual events that can be understood after some effort (Silvia 2005a; 2005b; 2005c; 2006).

For the theory, interest is the more central emotion that filmmakers and scriptwriters should seek in their audiences. Interest keeps the viewers in their seats, with the motivation of spending their mental resources on the audiovisual sequences and with high expectations for the future. Interest gives an

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

emotional structure to the video and provides the motivation to keep watching it (Tan, 1996). Although films and commercial videos differ in many aspects, the need to rise interest and to be able to influence the emotional experience of the viewer is common to both. The use of videos poses interesting psychological problems that are also common to films because they both integrate visual elements with music, sounds and narrative structure to convey meaning and emotions (Gross & Levenson 1995) and this combination can be used to rise interest for the presented products (in the case of commercial videos) or in the visual narrative and plot (in the case of films). Different aspects of the video design such as the shot composition, the movements of the camera, the music and sounds, the script for particular scenes interact to produce emotional reaction toward the product, and to influence the consumers' behaviour. Similarly, all these very different aspects of the video interact to conforming the users' experience of the product and capture their interest. Identifying the elements of videos that capture interest, and induce positive emotions, and understanding the way in which the audience experience them, is critical for the companies using videos with commercial goals (Kaikati & Kaikati 2004). Research should, therefore, provide answer to the question of how video contents can be used to enhance customers' experiences. Two recent studies (Silvia & Berg, 2011; Tarvainen et al., 2014) have tried to identify these elements by presenting people with short clips of pictures and asking viewers to rate the novelty, complexity, interest, and emotions elicited by the clips. Although the participants vary in their interest ratings, diverse combinations of novelty, complexity, and comprehensibility seem to predict interest. Similarly, in a recent study by Cañas-Bajo et al. (2017), participants were asked to signal the more interesting elements of a film and to indicate their emotional valence while watching the film, The results of this study showed that complex sequences that combined positive and negative emotions were rated as the more interesting parts of the film. In addition, studies should also be directed to identify elements that might differ for people with different cultural background.

Viewers' Experiences of Audio-Visual Contents

Experiencing a product involves creating a mental representation of the cognitive and emotional contents associated to the product. When researchers and designers discuss about users' (or consumers') experiences, they mean the conscious part of the symbolic representation of reality that we have in the mind (Newel & Simon, 1972). This means people have mental representations of their actions, their environment, their own internal states and their emotions, and that experience can be seen as the conscious part of mental representations (Saariluoma & Jokinen 2014). Consciousness is the result of appraisal processes involving three different information sources: the perceptual stimuli, the associative process in memory, and conscious reasoning processes (Roseman & Smith, 2001). These three processes proceed sequentially so that appraisal starts from the sensory and the perceptual processing of the stimuli whose aspects are detected and perceived by our senses. Information is then recovered from memory through fast and automatic associative processes, from the representation of the stimuli to the memory contents that start providing meaning to the events. Finally, the conscious reasoning process encodes the meaning and provides the bases of cognitive and emotional experiences that will endure in time and might influence behavior (Saariluoma & Jokinen, 2014). In this sense, appraisal processes define the cognitive aspect, which produces a specific emotional state. The result of the appraisal process determines whether an individual consciously likes or dislikes the stimuli (Scherer 2009; Saariluoma & Jokinen 2014; Eckler & Bolls 2011). Appraisal theory can also be applied to emotional states coming from audiovisual stimuli. Experiencing an audiovisual product involves creating a mental representation of the cognitive and the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

emotional contents associated with the product. It means that people have representations of the actions and the environment depicted in the product that combine with their own internal mental states. Videos might be useful tools to induce emotions and change consumers' perception of an object. The mental representations of a product can be influenced by the emotions attached to the audiovisual contents where the product is inserted (Moran, 1981). By exposing an individual to a video-based content about a product, external emotions will be created in consciousness. The information will be presented with sensitive additions that are implicit in the image and the sound, leading to a posterior appraisal when the viewer faces the product (Wang & Cheong, 2006).

Videos and other forms of audiovisual presentations could provide contexts that may influence appraisal processes by providing associations with the presented information and influencing the apperception of the product, in turn changing the viewer's emotional experience (Moggridge, 2010). Thus, the user experience includes thoughts, perceptions, or feelings when using a certain product, and the way that the product is presented may increase or decrease the quality of the experience (Albert, 2010; Albert & Tullis, 2013). Taking this approach might be critical for increasing the video's effectiveness in facilitating knowledge about the product and the customers' intention to buy it and other possible products from the same brand. Similarly, the impact of and interest of a video may be facilitated by understanding the factors affecting the audience's emotional and cognitive experiences of the video. Designing video for advertisements or to implement on-line shopping web sites should then start from understanding the different elements that influence the viewers' cognitive and emotional aspects (Garrett, 2010; Helfenstein, 2012; Norman, 2005).

Taking the users' experiences as a starting point is essential for increasing the effectiveness of the video in facilitating knowledge of the product. User-centred design aims to create products that meet the specific needs of the users in order to provide greater satisfaction and good experiences by reducing effort when interacting with the products (Norman 2005). As mentioned, identifying the elements that enhance users' experiences might be critical since some elements might not produce the desired experience for the users. For example, in the field of web design some studies have shown that adding features such as colours to facilitate the understanding or increasing the aesthetic of a product, could produce the opposite effect on the user experience by distracting users' attention and hinder understanding (Jiang & Benbasat 2004; Norman 2005). In audio-visual products, we might also find that introducing some technical or narrative features may have the opposite effect that the one intended. This is why focusing on the users' experiences might also be crucial for creating industrial applications that really meet the goals of the companies. However, this approach has not very frequently been used in studying online shopping. Users' approaches many times involves the use of methods that try to extract the mental representation of the user or consumer, and this in many occasions requires time consuming qualitative methods to assess mental contents. The study that we describe below represents one attempt to characterise the consumer's mental representation of the video contents and to identify the elements that capture the attention and interest of the viewer.

CROSSCULTURAL APPROACHES IN DESIGNING AUDIO-VISUAL CONTENTS

Understanding users' experience is even more important when shopping websites are aimed at a multicultural audience. For audio-visual elements to be successful, they need to adjust their contents to the type of product and to the cultural characteristics of the user. These cultural elements might influence

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

users' experiences of the product. An obvious advantage of online shopping is that costumers can be reached from many different geographical and cultural backgrounds, but this advantage would only materialize if the features of the online shop match the needs of the costumers. For this reason, cross-cultural studies from a users' experience perspective are needed for successful and efficient design of online shopping interfaces. To the extent that competition between companies has become globalized, it is important to understand the users' experiences and the impact of their products across cultures. Creating cross-cultural attractive interfaces where consumers from different cultural backgrounds can experience pleasant thoughts and feelings is especially critical (Van Slyke 2010). In this context, it is possible that an audiovisual product developed in a country and a cultural context does not have the same impact on the user from another country or culture. Although, it might be possible to find some features that users may generally consider usable and attractive (e.g., designs that follow the laws of Gestalt), many factors are strongly influenced by cultural values (Ito & Nakakoji 1996). Thus, the success of a video design may depend not only on the coordination of the quality of individual technical or narrative elements comprising it, but also on external factors such as historical and cultural aspects, which might influence the consumer (Dempster, 2006). Audience reception studies (Hall, 1966; Morley, 2006; Tomlinson 1999) have stressed the idea that the messages conveyed through the media are not passively accepted by the audience, and that people interpret their meaning based on their cultural background. For audio-visual elements to be successful, they need to be adjusted to the type of a product and to the cultural characteristics of the users. Audio-visual elements of products displayed in online shopping web sites convey culturally differing perceptions, which influence users' experiences of the products, and thus affects the adoption of e-commerce (Pavlou & Chai 2002).

Cross-cultural studies have also tried to identify a number of dimensions in which cultural differences affect the type of relationships and communication of companies and organizations (Hofstede 2010; Trompennaars 2010; Kasemsap 2016). For example, Hostfede identified six cultural dimensions in which countries differ (Power distance; Individualism vs. Collectivism; Uncertainty avoidance; Masculinity vs. Femininity; Long-term vs. Short-term orientation; Indulgence versus Restraint). Obviously these dimensions may have an effect on how people experience and react to audiovisual products.

One important dimension in online shopping web design is aesthetics since many aesthetics elements have been shown to positively influence purchase intentions (Bloch 1995). The appeal of the product in first impression formation seems to influence behaviour before consciously considering of buying a product (Lindgaard et al. 2006). However, it is not clear whether there are universal features for successful design and many studies have shown that aesthetic impressions may vary across individual personalities, genders, and ages (Moss & Gunn 2009; Cyr et al. 2010; Reinecke & Bernstein 2011; Hsiu-Feng 2014). Thus, aesthetic experiences involve interpretative interaction with several states and actions and thus cannot be considered merely as an immediate response (Carroll 2001). Additionally, important for the design of online shops is the many demonstrations that aesthetics vary with geographical location and culture (O'Connell 2014). For example, in their studies Reinecke and Gajos (Reinecke & Gajos 2014) observed that geographically close countries share similar visual preferences regarding color and visual complexity. For example, Finland and Russia preferred the lowest visual complexity and colorfulness of all countries they study. Similarly, Northern European countries seemed to prefer lower colorfulness than Southern European countries. In a similar vein, Marcus & Gould (2000) showed that Asians prefer brighter, more colourful and animated web sites than Westerners and that these more colourful web sites are sometimes perceived as information overload by the Westerners. In general, all these studies suggest that the countries with a regular exchange of cultural values share similar website preferences.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hence, in designing video contents to convey positive emotions toward a product or a brand, it is critical to consider the cultural dimensions in which people differ, not only when making aesthetic judgments, but also when considering other aspects of the products.

The idea of culturability introduced by Barber and Badre (1998) and extended by Cyr and Trevor-Smith (2004) summarizes the importance of cultural design. Culturability represents the mixture of design elements and culture to achieve usability in webs

…color, spatial organization, fonts, shapes, icons, and metaphors, geography, language, flags, sounds, and motion contribute to the design and content of a Web page, which directly affects the way that a user interacts with the site. (Badre 2001).

To address culturability in web and video design attention needs to be paid to many features (visual complexity, music, animation, narrative features, etc.) that can be culturally determined. Decision about these elements from the users' perspective will have an impact on the representation that people make of the product and this mental representation would impact apperception of the product. Thus, the use of videos as a possible solution for enhancing emotional experiences and interest in web shopping calls for research intending to understand the multiple elements of videos that can impact these representations.

Thus, differences in national and cultural dimensions may have an effect on how people experience and react to audiovisual products For example, in a recent cross-cultural study (Cañas-Bajo el al. 2015) images and videos of Iittala products (Finnish design) were compared with the goal of finding whether participants from Finland and Spain, appraised the designs similarly. In the study participants interacted with different audiovisual products depicting images/videos of the brand design. Through content analysis, four main categories defining the representation of the product were identified. Interestingly, the relative weight of these categories depended on nationality of the participants and on the type of visual presentation (image/video). The results indicated cultural differences in some dimensions (memory, usefulness) regarding the products, however the differences regarding these dimension were reduced when participants were shown videos instead of static images. These results suggest that videos are effective in inducing emotions and in changing consumers' perception of an object. Therefore, when designing web interfaces for internationally oriented web shops, audio-visual content may be used to reduce cultural differences and have more global impact.

This proposal can influence how we think of videos and use them. As we argued, videos can be used in online shopping as a way of offering customers a rich multimodal experience that can be closer to the experience of a physical shop (Childers et al., 2002; Reinecke & Gajos, 2014), but also audiovisual presentations of the products can be used to reduce the communication limits due to cultural differences by providing richer perceptual, multisensory experiences of the products.

Some theories propose (Barrat, 2012) that perceptual and cognitive processes are independent modules with different properties: perceptual processes are universal and independent of cultural factors, while cognition is prone to be influenced by culture. Accordingly, to the extent to which videos depend on perceptual processing, cultural and contextual factors should play a smaller role than for other type of object representations. Hence, videos can be used to reduce cultural differences and represent an useful strategy to become more global (Purcell, 2010). However, more evidence is needed to support these claims.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Are Users' Experiences of Videos Culturally Mediated?

Studies in this research area lack knowledge for identifying the factors that increase consumers' interest and the aspects of the video contents that help in creating pleasant users' experiences across different cultures (Cañas-Bajo et al. 2015). The aim of empirical case study that we describe below is to identify elements of audio-visual contents that enrich the product experience. Because the idea is to enhance cognitive and emotional mental contents of the consumer, the approach that we have taken in our research is to try to understand mental contents, and very specifically, what aspects of the displays capture interest in the viewers. The studies reviewed in the previous section also suggest that the answer to these questions might be culturally mediated. Hence, in our case study, (Cañas-Bajo & Silvennoinen, 2017) we have taken a cross-cultural approach and explored the mental contents and experiences of people from two countries, such as Finland and Spain, that are geographically distant (see Reinecke & Gajos 2014, for data showing differences in aesthetics judgment depending on geographical distance) and that also differ according to some Hostftede's cultural dimension. For instance, in the Hosftede's dimensions regarding "uncertainty avoidance", "collectivism" or "restrain" both countries present different results (Hofstede 2010). These differences has been found relevant when people from those countries buy new technological product (Cañas-Bajo et al., 2015).

In our study Spanish and Finnish participants were exposed to three videos representing Scandinavian design products and we investigated whether participants' mental representations of the videos include elements related to aesthetics qualities of the videos (e.g. the video is interesting, the video is colourful), but also if we could identify aesthetic emotions (Scherer 2009) and intentional aesthetics elements (Carroll 2001). According to Scherer an aesthetic experience is a mixture of interacting cognitive and emotional states when appraised produced aesthetic emotions (e.g. the video makes me feel nostalgic). Similarly, we tried to identify if intentional dimensions of aesthetic also impacted the viewers' experiences. Recent philosophical accounts of aesthetics in arts proposed that aesthetic experiences might also include appraisal of the aesthetics intention of specific element (e.g. the color is trying to capture my attention). From this view, the study not only assessed the elements of the video influencing the viewers' experience, but also aimed to provide support to the psychological reality of some aesthetics dimensions. In addition, we aimed to seek evidence of the importance of culture in modulating users' experiences of audiovisual products. Although appraisal theory and audience studies seem to suggest that culture plays a role in how we perceive and represent the external world, he question of the universality of emotions elicited by videos and films is subject to controversy. Thus, some cognitive theories assume that the capacity of making sense of a projected video is universal and not culturally determined (Barrat, 2012). According to this idea, a functioning perceptual system can visually allow any person to understand a film. According to the modularity hypothesis (Barrat, 2012), perceptual and cognitive processes are independent modules with different properties. As we mentioned, this hypothesis suggests that perceptual processes are universal and independent of cultural factors, while cognition is prone to be influenced by culture. Hence, to the extent that the presented stimuli depend on these modules, culture might have a larger or a smaller effect.

The universality of emotional processing is a classic question in the field of psychology (Darwin, 1872; Ekman & Friesen, 1971). Universalists have argued that basic emotions, such as hunger, fear, sadness, and so on, are universal and independent of culture. In their research and attempt to identify basic, culturally independent emotions, Ekman and Friesen (1971) provide evidence that facial emotional expressions are interpreted in similar ways by people from different cultures. The question of the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

universality of emotions is important for the video industry because if emotions are universal, video producers can use a culturally independent language (images) to convey such emotions. From this perspective, the visual language involved in video production (cuts, shots, angles, shadows, and so on) can be considered universal resources to convey culturally independent meanings and emotional experiences (Brown, 2003; Nielsen, 2005). From this standpoint, efficiently managing audiovisual resources should result in producing the desired emotional impact on the viewers.-

Against the idea of universality, the research on web and visual design has shown that aesthetic emotions may vary with culture. Additionally, communication studies have stressed that research should be targeted to features of the audience and that individual differences in culture and education may influence aesthetic emotions and the appreciation of cultural products. Films and other audiovisual products (series, clips, short films, etc.) are cultural items that can be influenced by individual factors regarding knowledge and orientation toward cultural products. Research on the so-called *cosmopolitan orientation* (Cleveland, et al., 2009; Hannerz, 1990; Skrbis & Woodward, 2007; Szerszynski & Urry, 2002; Woodward et a., 2008) has shown that knowledge and interest in cultural products, as well cultural habits of individuals, play a major role in the consumption of foreign products. *Cosmopolitan-oriented* people are identified by their interest in other cultures and geographically distant places and activities, as well as by their preference to consume products with different cultural combinations. A cosmopolitan orientation is usually associated with openness and compromise with social matters (Meuleman, & Savage, 2013).

In technology and design research, sociocultural differences and tendencies have been approached from the life-based design (LBD) paradigm (Leikas et al., 2013). This approach argues that individuals differ in their *forms of life* (Wittgenstein, 1958), constituting the habits, interests, and activities that they show in a given culture and context. Religious beliefs, support for a football team, and being part of a choir constitute forms of life. Cultural orientations are also considered aspects that comprise different forms of life (Rössel & Schroedter, 2015). In this theoretical context, designers have shown that people with different forms of life might vary in the types of activities and technological devices that are useful to them. From this perspective, designers need to pay attention to the aspects of individuals' lives and the contexts in which technology fits. Similarly, if cultural orientation and cosmopolitanism are considered forms of life, the design of cultural products should take into account the cultural habits of prospective consumers. People with interest in and openness to other cultures and consumers of cultural products may differ in many aspects that may impact their cultural experiences (Geertz, 1973). From this viewpoint, researchers and creators of audiovisual contents must consider different cultures and forms of life when targeting broad audiences. Thus, its approach is that culture may have an effect on how people experience and react to audiovisual products and that audiovisual companies should understand these different reactions when creating videos conforming to the cultural characteristics of its members. An audiovisual product created in a specific cultural context may not have the same impact on a viewer with a different cultural background. Thus, it is critical for designing video advertisements, industrial videos, or feature length films to understand viewers' experiences across cultures.

To sum up, different orientations and theoretical approaches assign varying roles and importance to cultural factors, and clearly more empirical studies are needed to try to understand the relative weight of universality and culturalism in the appreciation of video contents.

AN EMPIRICAL STUDY ON CULTURAL INFLUENCES ON VIDEO EXPERIENCES OF VIDEO PRESENTATION OF CULTURALLY LOADED PRODUCTS

Method

In the study described in, (Cañas-Bajo & Silvennoinen, 2017). Spanish (N = 20) and Finnish (N = 20) participants were exposed to three videos representing Scandinavian design products (Videos of Iitala products) with audio-dubbings presented in Finnish or in Spanish depending on the participants' nationality (See Appendix A). Both Finnish and Spanish participants were presented each of the videos and then asked: what thoughts and emotions does the video suggest to you? What video elements would you highlight?). Participants were tested individually in a quiet at the University of Granada, Spain (for the Spanish participants) or at the University of Jyväskylä in Finland (for the Finnish participants). We performed content analyses (Weber 1990) to extract the basic dimensions of the participants' mental representations of the videos. The approach for the content analysis was data-driven because the focus was on analyzing the type of feelings, emotions and impressions attached to different properties of the videos by the participants. Semantic units were transformed into content categories and then the frequencies of the semantic units within the categories were recorded in the following manner. Through several iterations of categorisations and mutual agreement between the authors, the categories and sub-categories were identified. First, we identified single words, phrases, and idioms that constituted semantic units for describing cognitive and emotional experiences produced by features of the videos. The second phase of the analysis was to critically evaluate the semantic units into initial categories. This classification phase of the coded semantic units resulted in 30 categories (see Appendix B). In the third analysis phase, second level categorisation was conducted to construct higher-level main categories from the initial sub-categories. These higher-level main categories were related to overall impression of the video (aesthetics, emotion, memory, desirability, etc.), narrative structures (plot, characters, and scenario), visual design (light, colour, shapes) and audio design. The frequency of semantic units within each category was counted for statistical analyses. These analyses were conducted to detect what aspects of the videos raised the users' interest and how these aspects affected the emotional and cognitive experiences of the viewers.

Results[1]

As mentioned, semantic units referring to video contents and emotional experiences elicited by them were classified according to four main categories. The first category was "Overall impression of the video" and contained subcategories related to overall features of the video. Three of these features referred to aesthetics dimensions: 1) Aesthetic persuasion: represented aesthetic evaluations regarding the intentionality of the video. Examples: "*They are trying to make you think about the shapes of everything*" "*to sell these objects is fine"; 2)* Aesthetic emotion: represents aesthetic evaluations of the general emotions experienced by the viewers. Examples of this subcategory are: "*I liked it a lot" "It did not make me feel anything" "The video makes me feel calm"*. 3) Aesthetic Quality: Represents quality attributes attached to the video by the viewers. Examples of this subcategory might be *"The video gives warmth" "I think it is interesting"*. In addition to aesthetics some units referred to what we termed: 4) Memory matches & Associations: represented mental associations such as memories and familiarity with the context. For example verbalization such as "*you wake up in the morning and breakfast is made*",

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

"*this suggests memories of Finland*". 5) Desirability: represented enhanced experience of the product through it presentation in the video. Examples: "*Makes you want to buy*"; and 6) Rhythm and length representing evaluation of the dynamics and rhythm of the footage. Examples: "*it felt like too long", "it moved forward all the time with a calm phase"*

The second main category referred to the "Narrative Structure of the video". This broad category also contained aesthetic element corresponding to the three aesthetics subcategories: persuasion, emotion *and* quality, but this time referring to narrative elements of the video. Examples of 1) aesthetic persuasion are "*that are tried to invent to represent some forms, how it can move and so on*", "*it didn't try to explain anything just showed*" 2) aesthetic emotion are "*Well sometimes analogies and metaphors annoy* me", "*this story didn't get me on its side concerning my emotions*" and 3) aesthetic quality are "*comparison between older and newer version was kind of useless*", "*There was interesting information that it takes 30 hours of work per one Aalto vase*". In addition, we identified units referring to the general description of the videos regarding the main idea perceived by the viewer. We termed this subcategory "Overall idea" and examples are "*they are talking about lamps and lights" "they are talking about design*" "*video featuring household items*". Some other subcategories within "Narrative structure" referred to evaluation of specific aspects of the storyline such as "*It explains how the design of curves and forms emerged" "It is interesting to see how it's done"(*Plots aspects subcategory); Evaluation of Character featured in the story line and their role: "*two artists involved in his work" "Then turn to the figure of the designer*"(Character subcategory); Evaluation of the Scenarios appearing in videos such as "*It seems the house of a couple" "what it does is use the Scandinavian landscape*" (Context subcategory); and Product presentation: evaluations on how the product is presented in the storyline. Examples: "*they see that each piece is unique" "Products were presented like in a catalogue*"

The third main category referred to elements of "Visual Design". Again some unit referred to the three aspects of aesthetics, persuasion, emotion, quality, as they related to visual elements. Examples of 1) aesthetic persuasion are "*all the elements a cozy atmosphere was tried to be created*", "*They try some kind of unity in here with the distribution of the elements*" 2) aesthetic emotion are "*peaceful feeling, because of the happy, bright images*", "*stillness, and safety inside the home walls*" and 3) aesthetic quality are "*the quality of the image was horrible and it disturbed me a lot"*, "*visually really stimulant*" In addition some units can be classified within the Composition subcategory that included evaluation of the visual composition of the element in the image. Examples are "*Quite a lot of graphic lines and details*", "*the video plays whit the camera angle of the view*"; some units were related to the Text subcategory that represented evaluation of the subtitles appearing in one of the videos. Example "*text, high-spaced video image were the core elements*"; Product presentation that included evaluations the way in which the product was visually and the fit within the general visual design. Examples: "*products were presented in their natural environment*". In addition, some subcategories referred to perceptual impressions; Materials referred to valuations regarding the material of the product and in other visual objects in the video. Examples: "*Soft wool and hard metal wire in that self, so that in here was lots of balancing elements*", "*there are a lot of wooden surfaces"*; Shapes referred to evaluation and comments on the visual shapes of object in the videos. Example: "*The shape of the vase was clearly the most important element here*"; Light referring to evaluations regarding the disposition of lights and lightning effects on the visual design. Examples: "*At the end of the video the room's lighting gets darker", "With the light and the glass, shadows came which looked nice"*; Colors included evaluation of the colors in the visual display and its integration into the overall visual design. Examples: "*there are lots of interesting colors in these*", "*Quite simple colors*"

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The fourth main category referred to the units regarding "Audio Design". Similarly, to the previous categories the Aesthetics categories regarding persuasion *(e.g. "Music was taken into account, and to all the parts that created the space),* emotion *(e.g. I like the music; The music wasn't supposed to disturb so much)* and quality were included as they applied to audio elements. (*e.g. the music suggests tranquility; the music influenced me)*. In addition, some units referred to the quality of the Narrator/off voice (e.g.*the voice was relaxing*); and to the ·Congruency of the music with other elements of the video (*e.g. Music and the forms were unified*; *I think the music wasn't the right one for this video*)

Figure 4 (see Appendix C) shows the mean number of verbalizations for each group (Finnish/Spanish) in each of the four higher-level categories. An analysis of variance (ANOVA) was carried out including Category as within-subjects variable and Nationality as between-subjects variable. Both main effects were significant (Category: $F(2, 81) = 41$; $p<.05$; $\eta_p = .52$; Nationality: $F(1, 38) = 8{,}38$; $p<.05$; $\eta = .12$). *"Overall impression of the video"* produced more verbalizations than the other categories (mean = 9.67). Moreover, Spanish reported more verbalizations (mean = 7.45) than Finish participants (mean = 5.24). Importantly, there was also a significant interaction, $F(2, 81) = 3{,}22$; $p<.05$; $\eta_p = .08$. Bonferroni corrected pairwise comparisons showed that there were significant differences between Spanish and Finnish participants in the first category: *"Overall impression of the product"* ($p<.01$) and a marginal difference in the fourth category *"audio design"* ($p= .056$). Thus, Spanish participants produced more verbalizations related to overall impression with the product and audio design (mean = 12.15) than Finnish participants (mean = 7.20).

When we analysed the specific subcategories within the overall categories, we observed that the differences in *"Overall impression"* between Spanish and Finish participants came from their verbalization regarding *Aesthetic quality* ($p < .05$) and *Memory matches* ($p < .05$). Similarly, we analysed the broader *"Audio design"* category and observed significant differences in Aesthetics persuasion ($p < .05$) with Spanish participants producing more verbalizations than Finnish participants, all other comparison within this category were not significant ($p > .05$).

Although the overall *"video design"* category did not reach significance, two of the subcategories within it did: *"Composition"* and *"Shapes"* were significant ($p < .05$), both showing more verbalizations by Spanish participants than by Finnish participants. Furthermore, the subcategory *"Plot"* was also significant ($p < .05$), although its higher-level category *"Narrative Structure"* was not. Again, Spanish made more verbalizations than Finnish.

DISCUSSION

The study reported here was designed to study possible differences between Spanish and Finnish participants in the emotional experiences elicited by videos in the context of online shopping. As we mentioned in the introduction, although design studies suggest that videos experiences might be culturally mediated, some psychological and film studies theories proposed that some emotional experiences are universal and that may be universal features that attract the viewers' interest. The results of the content analysis performed in the data form our empirical case study indicated that Finish and Spanish participants focused in different aspects of the videos. In general the Spanish participants produced more verbalizations than the Finnish, but importantly they also differed from the Finnish participants in their greater reliance in aspects related to the overall impression of the videos and in the audio categories. Regarding "overall impressions", the differences between the two groups came from the subcategory

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

"aesthetic quality" where the Spanish participants verbalised more global perceptual and emotional aspects of the video (*"the video is colourful, it suggests calm, it is interesting"*. etc.) than the Finnish participants. However, these differences did not appear when local and concrete visual features such as shapes, colours or lighting of specific objects or parts of the videos were considered. Similarly, Spanish participants represented mental associations and global contextual features (e.g. *you wake up in the morning and breakfast is made; reminds me of my town, etc.*"). Hence, the pattern of the verbalizations suggests that there are qualitative differences in the elements of the video contents that capture attention and interest for the two groups. Thus, the Spanish participants seem to pay more attention than the Finnish to contextual factors and memories reflecting an overall, global approach to the video contents, while Finnish participants seen to pay more attention to local functional features. It is also interesting that the only differences found in the category of visual design referred to more global features, such as composition or shapes and differences in the narrative structure dimension, also came from the Spanish mentioning more features related to the overall plot.

Although these differences might be due to a number of factors, this global approach to perception by the Spanish participants could also be associated to higher scores in Hostftede "collectivism" dimension and lower in "Restraint" of countries such as Spain. Obviously, this hypothesis is speculative and should be the focus of further research, but is lo consistent with cognitive research suggesting that cultural factors influence the focus with which people perceive the world. For example, Colzato et al (2008) compared neo-calvinist and atheist Dutch participants in the global-local task (Navon 1977) and showed that neo-Calvinists focused more on the local features composing global figures than the atheists.

Similarly, the dimension of audio design also showed differences between the Spanish and Finnish participants. Thus, the Spanish participants also paid more overall attention to the audio design of the video, especially to the emotional aspects composing aesthetics elements of the audio, than the Finnish participants. This difference may also be related to the differences in the "collectivism" dimension since cultural studies in emotion perception (Massuda et al. 2008) suggest the less individualistic societies pay more attention to contextual cues (e.g. music) to interpret emotions. These cultural differences in appraising the elements of the video that are brought into consciousness (overt verbalizations) by Finnish and Spanish viewers have implications for the design of the contents and aesthetics elements of the videos. Thus, our results suggest that videos designed for Spanish audiences should enhance global contextual and emotional features (global plot, global associations, global emotions suggested by light, color and music in the video), whereas audiovisual contents for Finnish viewers should also enhance local features of specific parts of the videos and individual objects. Because we have compared only two countries, we are not at the moment able to dissociate whether the obtained differences are due to geographical distance as suggested by the research by Reinecke & Gajos (2014), or to cultural dimension such "uncertainty avoidance", "collectivism" or "restrain" (Hofstede 2010). Further research should help to understand the underlying reasons for these differences and to generalise some of our conclusions to countries varying in geographical locations and cultural values.

Note that the pattern of results goes against theoretical positions suggesting that many aspects of videos and films evoke universal emotions and experiences. Modular theories (Barrat, 2012) assume that perceptual processes are universal and independent of cultural factors, while cognition is prone to be influenced by culture. From this assumption, videos that contain more perceptual features should be less prone to cultural modulation that other type of stimuli. However, our results seem to indicate that despite the rich perceptual features of the presented videos, they were represented and experienced differently by our Finish and Spanish participants. This suggests that video design should pay attention to

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

cultural factors when aiming to reach an international audience, and there is a need to adjust the video contents to the cultural characteristics of the viewers since the cognitive module may convey culturally different perceptions, which influence the viewers' experiences that may lead them to the adoption of e-commerce (Pavlou & Chai, 2002).

Although identifying aesthetic dimension was not the main goal of the study, it is important for aesthetics theories that we were able to identify in people mental representation of the video different aesthetic dimensions. Thus, we were able to classify units that reflected aesthetic contents of some visual, audio or narrative qualities of the video, separately from units that represented emotional aspects raised by the aesthetic quality of the video. But most interesting was the fact that we were able to identify in both Spanish and Finnish participants, what we called aesthetic persuasion that identifies elements clearly containing an interpretative dimension. Thus, within this dimension, mental contents as reflected by the participants' verbalizations referred to units where participants verbalized their interpretation of the intended meaning of different elements of the video (Carroll 2001).

These results indicate that audiovisual experiences involve evaluations of aesthetic persuasion regarding the overall impression of the video, and in more detail, concerning the narrative structure, visual design, and audio design. The elicitation of impression of aesthetic persuasion as a cognitive process can be explained with appraisal theory of emotion (Smith & Kirby 2001; Jokinen et al. 2015; Silvennoinen et al. 2015). Appraising aesthetic persuasion of an audiovisual representation requires information derived from all three-appraisal sources of information (Scherer 2009; Saariluoma & Jokinen 2014; Eckler & Bolls 2011). Thus, the evaluation of the aesthetic persuasion of a video includes perceiving the audiovisual stimuli, associations withdrawn from memories, and critical reasoning considering the intents of the aesthetics of the stimuli. In addition, aesthetic persuasion appraisals include visual literacy processes in detecting design methods and choices through which the aesthetic strives to create meanings, attitudes, and experiences and elicit emotions in the viewer.

Furthermore, overall impressions, narrative structure, visual and audio design involve aesthetic emotions and evaluations of aesthetic qualities. In appraisal theory of emotion, aesthetic emotion is conceptualized as a separate emotion typology from utilitarian emotions (Mastandrea 2014; Scherer 2009). Utilitarian emotions focus on their adaptive function, which help in adapting to certain stimuli or event. Aesthetic emotions are subjective affective responses to artifacts and to their intrinsic qualities (Mastandrea 2014). Thus, aesthetic emotion and aesthetic quality are intertwined in audiovisual experiences. Aesthetic emotion is a result of the cognitive evaluation of the significance of the event (in this case the audiovisual representation), this process also involves aesthetic qualities that are attributed to mentally represented information contents of the encountered audiovisual representation.

The categories presented in this paper illustrate the mentally represented contents of audiovisual experiences, and can be utilized to inform experience-driven design processes for online videos, and to understand the cognitive process of audiovisual experience from cross-cultural perspective. In addition, our study provides support to aesthetics theories that defend the multidimensional aspects of aesthetics including cognitive, emotional and intentional/interpretative aspects of it. Similarly, our results support and extend previous research suggesting that videos are effective in inducing emotions and in modulating consumers' perceptions. Thus, the mental representations of the viewers were affected by the properties associated to the audiovisual context.

A possible limitation of the study is the association of nationality to familiarity with the product and video presentation styles. Although, the use of familiar Finnish items had the advantage that allowed us to observe the influence of cultural aesthetics (for the Finnish participants the product aesthetics

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

matched their aesthetics preferences) in the mental representations, it is possible that the differences that we obtained between Finnish and Spanish participants might be due to familiarity with the product more than with other cultural dimensions. However, the fact that familiarity was only important for images but not when video was presented, suggests that there is more than familiarity in the different ways that Finnish and Spanish participants appraised and mentally represented the objects. Further research with unfamiliar items should try to dissociate the role of familiarity form other cultural dimensions.

SOLUTIONS, RECOMMENDATIONS AND FUTURE DIRECTIONS

The main focus of our study was to answer the question of whether the way of experiencing commercial videos depended of the cultural background of the viewers. Our results seem to suggest that it does. However, some limitations of our study force us to be cautious with our conclusions. First, although we have selected culturally different countries (according to Hofstede's [2010] dimensions) to conduct our observations, these countries come from occidental cultures where many values and forms of life are similar. Hence, an obvious line of research from our data is to directly compare emotions from many more different cultural orientations and larger variations in values, habits, and forms of life. Second, a similar reasoning can be applied to the selected videos since they all come from the same brand, with highly shared values and aesthetics. Additionally, in our attempt to control the selection of videos, we have picked videos depicting similar objects and using similar aesthetic elements and it is possible other styles and products are more open to cultural differences. Third, individual differences in cultural background, age, and expertise might provide better insights into individual and social factors influencing emotional experiences with films. Expert studies in many fields have been highly influential in revealing mental representations that differ for knowledgeable individuals. Reports involving radiologists or chess experts show that perceptions (apperceptions) of objects change with experience. Similarly, cultural background, openness to new experiences, educational level, and age yield different results (Saariluoma et al., 2016). Cultural globalization is a relatively new phenomenon that unevenly impregnates people's lives. Future research should explore the roles of these individual factors in film experience.

CONCLUSION

The results of our study suggest that cultural factors related to global versus local perception and emotions modulate the mental contents of video viewers, and therefore influence how users experience culturally designed products. Different elements composing the overall impression of the video, and the emotional perceptions of music aesthetics seem to impact differently Spanish and Finnish viewers. Thus, the elements of the medium in which the product is presented affects viewers in different ways and could be utilized in providing guidelines in designing product advertisements or web applications. An essential contribution of this paper to user psychology is that results clearly show that there are relevant cultural differences in the way the video elements are apperceived. Thus, this study builds a bridge between the field of user experience, user psychology, and cross-cultural psychology.

KEY TERMS AND DEFINITIONS

Audiovisual Experience: People's cognitive and emotional impression of audiovisually presented products and materials.

Audiovisual Representation: Mental representations that incorporate visual and audio elements of the perceptual stimuli.

Cross-Cultural Factors: Dimensions in which cultural differences impact the type of relations and the types of communication. In this context, these dimensions may influence the way usability and aesthetics are perceived.

Global Aesthetics: Subjective quality of objects, related to subjective sensori-emotional values and judgements of sentiment and taste.

Mental Representation: Symbolic mental contents that people have of their actions, environment, and their own internal states.

User-Centered Design: A model that seeks to satisfy the user's needs when interacting with artifacts by providing a good experience of this interaction without investing larger efforts.

Chapter 38
Gamification in E-Commerce: Enhancing Digital Customer Engagement Through Game Elements

Farid Huseynov
https://orcid.org/0000-0002-9936-0596
Gebze Technical University, Turkey

ABSTRACT

The gamification term, derived from the game concept, is the use of game-design elements (e.g., points, badges, levels, and leaderboards) in non-game contexts, often with the purpose of motivating and directing individuals' certain behaviors to achieve specific goals and outcomes. The contexts in which gamification is being researched and implemented include education, health, marketing, human resources, social networks, digital platforms, etc. Many studies conducted in various domains tried to understand and explain how gamification can influence or foster individuals' motivation to conduct goal-directed behavior digitally. In most of these conducted studies, significant impact of gamification on human behavior has been observed and proved. By presenting academic findings from literature and discussing real-world implementation examples from the relevant domain, this study assesses the role of digital gamification in e-commerce domain. This chapter shows how various digital game design elements can influence consumer behavior in different e-commerce platforms.

GAMIFICATION CONCEPT

Humans have been playing games for thousands of years. Games are one of the oldest forms of human social interaction. The relevant literature includes various definitions of the game. Game is defined as a system in which players engage in an artificial conflict, defined by rules, which results in a quantifiable outcome (Salen and Zimmerman, 2004). All games have one or many of the following features: rules; structure, voluntary play, player effort, player investment, quantifiable outcomes, conflict, resolution, etc. (Juul, 2003; Seaborn and Fels, 2015). Two related but not exactly the same concepts game and play are being used interchangeable in many contexts. In game studies, the distinction between game and

play is usually tied back to the concepts of paidia and ludus which have been put forward by Caillois (2001). Caillois (2001) placed the two complementary terms paidia and ludus at opposite ends of a play continuum. Paidia (i.e., playing) is the main power of improvisation, expressiveness, spontaneity, and joy which is usually present in children's free play. On the other hand, Ludus (i.e., gaming) consists of formal play including rules and arbitrary obstacles that defines winners and losers and commonly manifests itself in board games and video games. The play is broader than the game and encompasses it. While playing refers to a more free form, expressive, improvisational meanings and behaviors, gaming refers to playing which is structured by rules and competitive strife toward goals (Salen and Zimmerman, 2004).

The term gamification derived from the game concept. This term was used for the first time in 2002 by Nick Pelling, a British programmer and video game designer for digital products. However, gamification term did not become popular and mainstream until 2010. In the relevant literature, there is no universal definition of gamification. However, the gamification definition of Deterding, Dixon, Khaled, & Nacke (2011a) is the one that is widely accepted and used. According to Deterding et al. (2011a) gamification is the use of game design elements in non-game contexts. The central idea behind this innovative technique is to utilize game-design elements (e.g., points, badges, levels, achievements, and leaderboards) in real-world contexts (e.g., business, education, etc.), with the goal of directing and motivating certain behaviors of individuals digitally. That is, gamification utilizes game mechanics for non-entertainment purposes. This technique is more about motivating people and encouraging them to show the behavior you want. Gamification and game are different in terms of the purpose of play. Main focuses of gamification are changing players' behavior, digital engagement with their environment towards achieving meaningful interaction and engagement and potentially achieve rewards. However, games focus more on entertainment and pleasure (Xu, Buhalis, & Weber, 2017). Gamification applies elements of "gamefulness", "gameful interaction", and "gameful design" for a specific intention (Deterding et al., 2011a). Gamefulness refers to the experiential and behavioral quality of playing; gameful interaction refers to the objects, tools and contexts that bring about the experience of gamefulness, and gameful design refers to the designing for gamefulness by utilizing game design elements. Gamification is more related with games (ludus-type) than with play or playfulness (paidia-type) (Salen and Zimmerman, 2004).

Game design elements are the main building blocks of gamified applications. Game elements are being applied in diverse type of non-game contexts with varying degrees of success. There are various types of game design element and depending on the type and purpose of application, numerous game elements can be utilized in a single application. The most common type of game elements encountered in gamified platforms include points, badges, levels, leaderboards, performance graphs, meaningful stories, avatars, virtual currencies, customization (personalization), tasks, social network features, and teammates. Table 1 shows the descriptions of each game design element mentioned above.

In the related literature, it is possible to see various alternative terms which are being used to refer to gamification, such as 'serious games', "applied games" 'game based learning', 'games for a purpose', 'productivity games', 'behavioral games', etc. The most common interchangeable used term with gamification is the "serious games". Even though they are related, they refer to different things. Serious games which was introduced to the literature by Abt (1970) refer to the games designed for a purpose of educating rather than merely entertaining users. Whilst serious games do entertain up to certain extent, they go beyond and mainly focus on training and skill development, educating, and behavioral and attitudinal change process. The term game elements helps in distinguishing gamification from serious games (Deterding et al., 2011a). While gamification refers to the use of distinct game elements embedded in real-world contexts, serious games are fully-developed games serving a specific, non-entertainment

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

purpose (Deterding et al., 2011a; Yongwen, Johnson, Moore, Brewer, & Takayama, 2013). It is possible to see serious games in action in various industries such as education, health care, aviation, military, engineering, etc. While gamification is the use of various game elements integrated in real-life contexts, serious games are standalone games which carry a specific, non-entertainment purpose (Deterding et al., 2011a; Yongwen et al., 2013). It is possible to see serious games in action in various industries such as education, health care, aviation, military, engineering, etc.

Table 1. Description of game design elements

Game Element	Description	Source
Points	Points are usually accumulated as a result of successful execution of certain activities in gamified environment. The main purpose of points is to numerically show user's progress on the given activity. Points can be classified as experience points, redeemable points, reputation points, etc. Points also play an important role in providing continous and immediate feedback about performance of the users.	Werbach and Hunter, 2012; Sailer, Hense, Mandl, & Klevers, 2013
Badges	Badges visually represents achievements of user. They can be earned and collected in the gamified applications. They are usually earned as a result of completion of particular activity or accumlation of certain amount of points. Similar to points they also provide feedback about user performance on the gamified platform.	Werbach and Hunter, 2012; Sailer et al., 2013
Levels	Levels represents user advancements in the gamified platform. Levels can be progressed by collecting points, conducting certain actions, completing specific tasks, etc. Levels can be utilized to stimulate the desire to go after the more challenging levels on the given platform.	Gatautis, Banyte, Piligrimiene, Vitkauskaite, & Tarute, 2016
Leaderboards	Leaderboards enable to rank users according to their relative success, measuring them against a certain success criterion. Leaderboards can foster competition and can create social pressure which will increase the users' level of engagement, participation and learning.	Burguillo, 2010; Costa, Wehbe, Robb, & Nacke, 2013
Performance graphs	Performance graphs provide information about the player's performance compared to their preceding performance during a game. In opposite to leaderboards, the users' performance is not compared to other users' performance in this kind of graphs. Instead, such kind of graphs evaluate the player's own performance over time.	Sailer et al., 2013
Meaningful stories	Meaningful stories are game design elements that do not relate to the player's performance. This kind of game design elements contextualizes activities and characters in the game, and gives them meaning. They can alter the meaning of real world activities by adding a narrative overlay. Narrative contexts can be oriented towards real, non-game contexts or they can act as analogies of real world settings.	Kapp, 2012;
Avatars	Avatars visually represents users within gamified platforms. Avatars are usually picked out or designed by the users. They are used to identify and differentiate users from others in a given platform.	Werbach & Hunter, 2012; Kapp, 2012
Virtual currency	Virtual currencies can be obtained by successfully completing activities and tasks on the gamified environment and these currencies can be used to purchase virtual items.	Liu, Alexandrova, & Nakajima, 2011
Customization/ Personalization	It refers to activities which enable users to modify certain aspects of the interface up to certain degree which brings personal relevance to the users.	Marathe and Sundar, 2011
Tasks	A quest or small mission is a task in that users complete in order to gain a certain rewards	Sailer et al., 2013
Social network features	They are social-related gamification features which include messaging, blogging, chatting and connecting to social networks	Aparicio, 2012
Teammates	This kind of features enable creation of team of players that cooperate towards achieving a shared objective.	Werbach and Hunter, 2012

IMPLEMENTATION EXAMPLES OF GAMIFICATION IN E-COMMERCE

Electronic commerce (a.k.a. e-commerce) refers to commercial transactions conducted over electronic networks, primarily the internet. The most common type of e-commerce that we encounter on the Internet is online shopping. However, e-commerce is not just limited to online shopping. E-commerce is an umbrella term covering many different types of other electronic transactions such as online banking, online ticketing, online gambling, online taxing and various types of electronic government services. With the popularization of the social media and advancements in mobile digital platforms we also started to see new subsets of e-commerce such as social commerce and mobile commerce both of which provides new possibilities and opportunities to business owners and customers. Among many other business models on the Internet business-to-consumer (B2C) is the most common one. B2C e-commerce refers to a transaction conducted over the Internet between businesses and end consumers. According to eMarketer (2019), global B2C ecommerce sales will approach 5 trillion U.S. dollars by 2021. When it is thought about the number of global active internet users which were approximately 4.33 billion as of July 2019 (Statista, 2019), this large volume of global e-commerce sales is not surprising and expected to increase even more in the future.

It is now very easier and less costly than ever to start a new business online thanks to the advancements in the Internet, web and mobile technologies. On the other side, it is also very convenient and less costly for consumers to get product and services from many potential suppliers located in various locations around the globe. For the business owners, the first and foremost difficulty is how to attract to and keep customers at their online business platforms. Internet has considerably reduced the online consumers' switching costs which refer to the costs that consumers incur as a result of changing their brands, suppliers, or products. Online business owners are well aware of the fact that on the Internet their customers are just few clicks away from their direct competitors. Therefore, they continuously try to discover and impose new switching costs on their consumers by differentiating their products and services, introducing entirely new business models, etc. That is, they always try to find new means to make their customers to stay with them. Gamification is one of the technique that managers have started to utilize in their online businesses in order to increase customer experience, engagement and retention rate. In recent years, business owners started to leverage the gamification techniques in various types of online business platforms. By incorporating game elements to their online business platforms, business owners are trying to encourage and motivate customers to use their products and services more. Through gamification technique online business owners are trying to create a fun, challenging and persuasive environments which could possible encourage customers to engage with brand and offered services more and discourage them to switch to competitors' services.

Global companies from diverse sectors have started to incorporate gamification techniques into their marketing strategies. Among these companies are Starbucks, Amazon, eBay, Expedia, TripAdvisor, Airbnb, Delta Air Lines, etc. According to the estimations, the gamification market is expected to grow from 4.91 billion U.S. dollars in 2016 to approximately 12 billion in 2021 (Statista, 2018). One important thing to note is that gamified e-commerce does not mean transforming your online business (e.g. online store) into pure game. The main idea is to take game design elements such as points, badges, levels, leaderboards, avatars, virtual currencies, tasks and implement these elements in various e-commerce platforms, with the goal of motivating and encouraging the specific behavior you want. To put it in other words, gamification in e-commerce is the use of game design elements in an e-commerce context to drive

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

customer engagement and motivate the desired action which could be the purchase frequency, positive reviews, dissemination of positive word of mouth, increased retention and loyalty, etc.

One of the most commonly used game design element in various gamified platforms are points. Points are usually accumulated as a result of successful execution of given activity and they numerically show user's progress (Werbach and Hunter, 2012; Sailer et al., 2013). Points enable to measure users' in-game behavior, and they serve as continuous and immediate feedback and as a reward (Sailer et al., 2013). In e-commerce businesses, point-based rewarding systems is one of the commonly utilized technique under loyalty programs. Through point-based system, customers earn reward points for each purchase they make or for each activity they successfully complete. Later, customers are usually offered various options to redeem these collected points. Depending on the nature of the business and policies of the loyalty program collected points can be converted into money, used as a discount, or exchanged for other valuable things. In order to increase customers' engagement and motivate them to conduct certain behavior even more, online business owners implement another type of gamified feature which is a tier system. This tier system corresponds to the levels advanced in games. Levels shows user progress in the gamified environment and they are advanced by collecting certain amount of points or successfully completing certain tasks (Gatautis et al., 2016). Starbucks, a coffee company, with its Starbucks Rewards program successfully implements above mentioned gamification features. Members of the Starbucks Rewards program collect stars as points on almost everything they purchase. Every time customers pay using a mobile application, they collect two stars for every dollar. When customers collect enough stars they can redeem these collected stars for free drinks or food at Starbucks stores. For example, at 25 stars, customers can add one customization to their drink for free; at 50, they can get a free brewed hot coffee, bakery item, or hot tea; at 150, they can get a free handcrafted drink, hot breakfast item, or parfait; at 200, they can get a free lunch sandwich, protein box, or salad; and at 400, they can redeem them for select merchandise or at-home coffee. Another feature of gamification which is also successfully implemented by Starbucks in its loyalty program is tier system. When customers sign up for Starbucks Rewards they start at the Green level. To get to Gold level, they need to earn 300 points in a 12-month period. Gold Level is the top tier of Starbucks' loyalty program that offers some benefits to frequent customers. Those perks include monthly double star days where members can earn 4 stars per $1, a personalized gold card, and a free food or drink item for every 125 stars collected. Tier system is an excellent gamification feature that provides customers with a goal to shoot for, makes them addicted to the brand, and feel valued with additional benefits offered to them at different levels. Levels can be utilized to stimulate the desire to follow the more challenging levels on the given platform. This tier system also allows businesses to segment customers according to their behavioral characteristics (e.g., spending behavior) which will help to carry out customized marketing strategies according to given segments characteristics.

Points and tier system are also successfully applied in civil aviation sector. Many airline companies have frequent-flyer programs which enable enrolled customers to accumulate points, also known as miles, which can be redeemed for air travel or other rewards. Customers earn mile points every time they fly with that company. The number of mile points customers earn depends on several factors such as route, class, tier, etc. Customers can advance through the tiers and take advantage of exclusive membership benefits as they earn more mile points. The most common types of tiers which are encountered in airline companies are Silver, Gold and Platinum levels. Most airline companies have mobile app which enable customers to track their mile points. Some of these mobile apps even enable customers to set travel goals and earn miles towards them.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

TripAdvisor, the world's largest online travel platform, is one of the companies that are effectively utilizing game design elements in its online platforms. Travelers around the world use the company's web site and mobile app to reach more than 760 million reviews and opinions of more than 8 million accommodations, restaurants, experiences, airlines and cruises. In order to increase number and quality of user contributions (e.g., review, photo, video, forum post, etc.), TripAdvisor is utilizing various game design elements such as points, levels and badges in their online platforms. Every time users contribute to TripAdvisor, they receive TripCollective points. For example, each review worth 100 points, each photo worth 30 points, each forum post worth 20 points, etc. There are six TripCollective levels and users advance levels by collecting points. While level one requires 300 points, level six corresponds to 10.000 points. Another game design element that TripAdvisor is effectively utilizing are the badges. Badges are one of the most commonly utilized game design element in many gamified platforms. They are among the most visible elements of gamification. Badges visually represents status, progress and achievements of user and they can be either earned or collected in the gamified platforms. This gamification feature provide feedback about user performance on the gamified platform (Werbach and Hunter, 2012; Sailer et al., 2013). Badges are a way of showing users' knowledge and expertise. In TripAdvsior platform, users collect badges as they contribute to the system by writing reviews or by adding other posts (e.g., photos, videos, etc.). Users also get badges in recognition of how helpful or useful their review or other posts have been. Some of the available badges in TripAdvisor are as follows. There is a New Reviewer badge which you collect by writing your first review. The more you write, the higher level badge you receive in this given category. There is a Passport Badge which recognizes the users for being world travelers. Once users add reviews for places in at least two destinations in the world, they get their Passport badge. There is also an Explorer badge which are given to the users for being one of the first to review a hotel, restaurant, or attraction in a given language. These various types of virtual badges act as incentives to encourage users for more reviews.

Gamification has also been utilized in online gambling platforms (e.g., online casino, online sports betting) in increasing player retention and creating loyalty. Most of these online platforms use various gamification techniques which can include special sign up bonus points or referral rewards for the purpose of increasing membership. In such platforms, players are usually rewarded with loyalty points if they stick around and use the given platform on a regular basis. These platforms are utilizing another well-known game design element which is leaderboards. Leaderboards rank players according to their relative success and they can stimulate competition and create a social pressure which will increase players' engagement and participation levels (Burguillo, 2010; Costa et al., 2013). Through leaderboards players can monitor their status and they can see where they rank on the specific event which will encourage them to return back to the given platform to improve their positions on the leaderboards. Most of these platforms also enable players share their position in leaderboards, their badges and other performance indicators on various social networking platforms, which in turn brings them additional bonus points and loyalty points. These game design elements on various type of online gambling platforms not only encourage customers to play more but also increase their motivation and loyalty levels towards the given platform.

Nike is one of the companies that successfully utilize gamification technology in sports domain. For many people, the lack of motivation is the main barrier for consistent training. Without a running partner, a personal trainer, or some other form of encouragement, it's difficult for people to acquire the habit. In order to address this issue Nike have introduced Nike Run Club app which is available for both android and iOS platforms. This mobile app includes necessary gamification and other tools that can motive someone to run better. These tools include, but not limited to GPS run tracking, audio guided runs,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

distance challenges (weekly, monthly and custom), competition on leaderboards, trophies and badges for celebrating achievements, sharing activities and achievements with friends on various online platforms, customized coaching plans for user goals, and nonstop motivation from friends. This gamified mobile app is a very nice example of how a brand can use game elements to get connected with its customers. This gamified app not only motivates users to do sports and engage with brand, but also enables Nike to collect valuable data about individual users which can be used for marketing purposes.

Businesses continuously seek for creative marketing strategies to promote their business and attract more and more consumers to their brand. Gamification has become a popular strategy for managers to keep their existing customers and reach potential ones over online platforms. Above mentioned examples have showed how companies in various fields successfully implement game design elements in attracting more customers and giving them a reason to keep returning to the brand and purchase or use products and services more.

GAMIFICATION AND USER MOTIVATION

Gamification technique has attracted attention of both scholars and practitioners because of its very wide application in various areas. Gamification has been studied in many different areas including but not limited to the following: education (Landers & Landers, 2014, Toda, Carmo, Silva, Bittencourt, & Isotani, 2019), crowdsourcing (Liu et al, 2011; Mekler, Brühlmann, Tuch, & Opwis, 2015), data-collection (Downes-Le Guin, Baker, Mechling, & Ruyle, 2012), health (Jones, Madden, & Wengreen, 2014; Cechetti, Bellei, Biduski, Mazuco Rodriguez, Roman, & De Marchi, 2019), marketing (Hofacker, Ruyter, Lurie, Manchanda, & Donaldson, 2016; Hamari, 2015; Hwang and Choi, 2019), social networks (Thom, Millen, & Dimicco, 2012), environmental protection (Liu et al, 2011), order handling (Sailer, Hense, Mayr, & Mandl, 2017) and workplace management (Mitchell, Schuster, & Jin, 2018). All of the above studies conducted in various domains tried to understand and explain how gamification can influence or foster individuals' motivation to conduct goal-directed behavior.

One of the main theoretical framework adopted in gamification studies is the self-determination theory (Deci & Ryan, 1985; Ryan & Deci, 2002). Many studies in the relevant field tried to explain user motivation and behavior within the scope of self-determination theory. Self-determination theory is a psychological framework which helps to understand human motivation. According to self-determination theory, individuals' motivation to conduct a certain behavior can be explained through self-determined continuum. This continuum ranges from non-self-determined to self-determined. At the right end of the self-determined continuum, there is intrinsic motivation in which individuals engage in an activity for potential pleasure and satisfaction that may be derived from it. At the left end of this continuum there is amotivation, which is lack of motivation or intention to engage in a given behavior. In the middle of this continuum there is extrinsic motivation in which individuals' behavior is driven by external factors (e.g., rewards or punishments) which are unrelated to the activity itself (Deci & Ryan, 1985; Ryan & Deci, 2000b).

Intrinsic and extrinsic motivation play an important role in shaping who we are and how we behave (Deci & Ryan, 2008). Extrinsic motivation is a drive to behave in certain ways based on external sources and it results in external rewards (Deci & Ryan, 1985). Extrinsic motivation occurs when an individual is motivated to perform a particular behavior or engage in a particular activity to earn certain rewards or avoid possible punishments. In other words under extrinsic motivation individuals engage in a behavior

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

not because they find it pleasant and satisfying or because they enjoy it but in order to get something in return or escape from possible negative consequences. In a professional environment sources of extrinsic motivation can be money, awards, promotion, employee evaluations, etc. On the other side, in intrinsic motivation there are internal driving factors that inspire us to behave in a particular way, including our core values, our interests, and our personal sense of morality. That is, under intrinsic motivation individuals perform a behavior or an activity for its own sake rather than the desire for some external reward or fear of any punishment. The most productive force behind people's behavior is commonly considered as intrinsic motivation (Deci & Ryan, 2000; Ryan & Deci, 2000b). Therefore, when people are motivated intrinsically, they have a strong desire for the activity itself and enjoy it. Although intrinsic motivation is a stronger drive of behavior (Grant, 2008; Ryan, Frederick, Lepes, Rubio, & Sheldon, 1997), extrinsic motivation also has a behavioral impact (Cerasoli, Nicklin, & Ford, 2014). Gamification should combine intrinsic with extrinsic motivation to increase motivation and engagement (Deterding, Sicart, Nacke, O'Hara, & Dixon, 2011b). Using only extrinsic rewards may have negative behavioral impacts as study of Deci, Koestner, and Ryan (1999) suggested that extrinsic rewards can undermine intrinsic motivation to complete a task, especially if the task is engaging, interesting and beneficial to the user. This implies that if individuals find a given task enjoyable, interesting and engaging, that is, if they are already intrinsically motivated to the given task, the addition of specific reward structures could decrease already existing intrinsic motivation toward the given task.

Cognitive Evaluation Theory (CET) which is a sub-theory within self-determination theory further explains that individuals are driven by three fundamental psychological needs: autonomy, competence, and relatedness. Satisfaction of these three psychological needs is very important for an individual's intrinsic motivation (Ryan & Deci, 2000a). The need for competence refers to being capable and competent in controlling outcome of an activity and experience mastery of that given task. Need for autonomy refers to individuals' need to actively participate in determining their own behavior. The need for relatedness refers to need to be connected to and experience caring for others. Basic Psychological Needs Theory (BPNT) which is another sub-theory within self-determination theory states that satisfaction of autonomy, competence, and relatedness positively influences the psychological well-being of individuals (Ryan & Deci, 2000c). On the contrary, any situations or activities that impede these psychological needs would negatively impact wellness. In gamification literature, a number of studies showed the influence of various gamification features on individuals' intrinsic need satisfaction, motivation and engagement (Peng, Lin, Pfeiffer, & Winn, 2012; Thom, Millen, & Dimicco, 2012; Sailer et al., 2017; Xi and Hamari, 2019; Deterding et al., 2011a; Cechetti et al., 2019; Mekler et al., 2015; Sailer et al. 2013). The following paragraphs discusses the important findings of some of these selected studies.

In their study Xi and Hamari (2019) assessed the relationship between different gamification features (immersion, achievement and social-related features) and intrinsic need satisfaction (autonomy, competence and relatedness). Immersion-related gamification features mainly include avatars, role-play mechanics, storytellings, narrative structures, customization, etc. and they mainly try to immerse the player in a self-directed inquisitive activity. Achievement gamification features include points, virtual currency, badges, progress bars, leaderboards, etc. and they enable users to monitor their progress and performance. Social-relatedness features include groups, messages, blogs, connection to social networks and these features enable users to reinforce interpersonal relationships and strengthen social participation in gamified platforms. Xi and Hamari (2019) showed that immersion-related gamification features were only positively associated with autonomy need satisfaction. However, achievement and social-related features were found to be positively associated with all of the aspects of intrinsic need satisfaction (i.e.,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

autonomy, competence and relatedness). Their findings showed that gamification features such as badges, leaderboards, levels, tasks, etc. offer not only immediate feedback (which can engage users and generate flow experience) and skill development, but also help users to understand others in a gamified environment. This research also showed that social-related features not only facilitate the low-cost information exchange where users can acquire more skills and knowledge to achieve a sense of accomplishment but also enable users to get relatedness need satisfaction by communicating, talk and connecting with others in the gamified environment.

In an experimental study conducted over enterprise social network system (SNS) Thom et al. (2012) assessed the influence of extrinsic rewards on intrinsic motivation to conduct a given task. The extrinsic rewards in this experimental study was point-based incentive system on SNS. The goal of the incentive system was to encourage content contribution on SNS, so points were awarded for the addition of lists, photos and comments. In this experimental study it was found that the removal of the points system had a significant negative impact on the user activity. This study finding showed that gamification based extrinsic rewards do actually influence a segment of the user population to participate more intensely in a given activity.

Peng et al. (2012) manipulated game features and tried to assess how these manipulated game features effect players' three basic psychological needs. The results showed that availability of several choices in the game (e.g., choice of avatar customization, choice of how to grow strength of avatars) supported players' need satisfaction of autonomy. Additionally, the game's ability to dynamically adjusted difficulty levels based on players' performance and indicators for the players to see their achievements (e.g., heroism meter, achievement badges) led to increased satisfaction of the need for competence.

In another study conducted in a health domain Cechetti et al. (2019) assessed the influence of gamified elements on user intrinsic motivation to engage in particular behavior. Within the scope of this study two versions of an m-Health application were developed, one with the gamified elements and one without these elements. It was found that the app without gamification features did not necessarily motivate participants to change their habits regarding the specific treatment. On the other hand, gamified app resulted in higher user motivation and engagement. For example, gamification promoted the monitoring of blood glucose by participants, letting the participants acquire this habit.

Finally, in their study Sailer et al. (2017) utilized self-determination theory to understand motivational power of various game design elements on the fulfilment of basic psychological needs (i.e., perceived competence, relatedness, and autonomy). Their results showed that badges, leaderboards, and performance graphs positively influence competence need satisfaction and perceived task meaningfulness. Avatars, meaningful stories, and teammates were found to have impact on social relatedness. Sailer et al. (2017) stressed that gamification can have many forms and can include game elements in many different ways; therefore, it is not appropriate to study the motivational effects of gamification as a uniform concept. They suggested that the relationship between different game design elements and human behavior should be the main focus point. The findings of the above mentioned studies confirms the suggestion of Sailer et al. (2017) on the potential motivational effects of various game design elements. Therefore, in order to get the desired results careful attention should be paid to potential influences of various game design elements while designing gamified environments.

Another commonly utilized theories in gamification studies is Technology Acceptance Model (TAM) (Davis, 1989). TAM is an information systems theory that models how individuals come to accept and use a technology. TAM proposes that the acceptability and adoption of an information systems and technologies is determined by two main factors which are perceived usefulness (PU) and perceived ease of use

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(PEOU). PU refers to the degree to which an individual believes that the use of a system will improve his performance. On the other side, PEOU refers to the degree to which an individual believes that the use of a system will be easy and effortless. In TAM, perceived usefulness and perceived ease of use are the fundamental factors that determine users' attitude toward using a new technology. That is, when new technological innovation is perceived to be useful and ease to use, users develop positive attitudes towards it. Besides, perceived ease of use is a significant predictor of usefulness of a given technology. According to TAM, attitude toward a particular technological product significantly influences intention to use the given product. This model also suggests that perceptions about usefulness of a given technology directly influences users' intention to use it. Behavioral intention represents users' readiness to conduct a given behavior and it plays a significant role in influencing users' actual behavior. These proposed suggestions of TAM were examined and proved in various types of information system studies (Turner, Kitchenham, Brereton, Charters, & Budgen, 2010). Researchers also implemented TAM in gamification domain to analyze and understand the role of various gamification elements on users' behavioral intention to use the platforms in which such techniques are implemented. Significant positive influence of gamification elements on user behavior was observed in the studies that utilized TAM (Rodrigues, Oliveira, & Costa, 2016; Huang, Chen, & Liu, 2019; García-Jurado, Castro-González, Torres-Jiménez, & Leal-Rodríguez, 2019). Literature showed that gamification positively influences the users' perceptions about usefulness and ease of use of the platform in which gamified elements are implemented. Users' favorable perceptions about gamified platforms, in turn, plays an important role in forming favorable attitudes towards such platforms. Developing favorable attitude in the mind of consumers is very critical as it leads to behavioral intention to use platforms under question.

GAMIFICATION AND ONLINE CONSUMER BEHAVIOR

In the relevant literature, the influence of gamification on online consumer behavior has been assessed in numerous studies in various e-commerce contexts such as online retailing, online banking, online gambling, online travel, etc. Studies showed that gamification techniques do have a significant influence on online consumer behavior. Research findings showed that use of gamification e-commerce domain modify online consumer behaviors by increasing the level of interest, motivation, engagement, retention and loyalty. The following paragraphs discusses the findings of the selected studies from various e-commerce domains.

In their study, Hwang and Choi (2019) investigated whether and how gamified loyalty programs impact consumer loyalty toward loyalty programs and behavioral intentions to use them, along with the role of the type of rewards, namely self-oriented and altruistic rewards. Altruistic rewards refer to rewards that are designed to benefit someone other than the loyalty program participant (e.g., donation of rewards to others in need or to the communities), in contrast self-oriented rewards refer to rewards designed to benefit the participants themselves. Their study showed that gamified loyalty programs engender significantly greater consumer loyalty to LPs than do conventional LPs. The results confirmed that gamified loyalty programs (vs. conventional ones) increased consumer loyalty toward loyalty programs which in turn enhanced consumers' participation intention in loyalty programs and mobile app download intention. In this study it was also found that self-oriented rewards have a greater positive impact on consumer LP loyalty than do altruistic rewards.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Also, Hofacker et al. (2016) developed a conceptual framework of gamification in the mobile marketing context. This framework defined the elements of gamification as story, mechanics, aesthetics, and technology, all of which influence marketing outcomes, including engagement, attitude, purchase, repurchase, and retention. Their model posits that consumer-related factors (e.g., characteristics, goals, and usage context) and product-related factors (e.g., type and life cycle) moderate the impact of gamification elements on marketing outcomes.

Eisingerich (2019) demonstrated how gamification can raise customer engagement. They analyzed relationships among gamification principles, individuals' engagement behaviors, and digital sales. In their study, they identified several gamification principles - social interaction, sense of control, goals, progress tracking, rewards, and prompts – which believed to play an important role in inducing people to take action. In addition to these gamification principles, they identified two main mechanisms - hope and compulsion - that explain how these principles influence behaviors. Hope refers to individuals' desire for a goal-congruent possible outcome. It represents a feeling that a currently unsatisfying situation can be improved. On the other side compulsion refers to a response to uncontrollable, repetitive and sometimes senseless desire to engage in certain behaviors. They found that hope positively mediates the relationship between gamification principles and customer engagement. On the contrary, compulsion was found to reduce the possibility of customer engagement. Compulsion was reported to have only a slight impact on customer engagement. That is, at the beginning individuals may feel forced to use and check their apps, however this compulsion will tend to decline over time. On the other side, hope is a stronger driver of customer engagement. Hope motivates and encourages customers to change their behaviors and makes them to take decisive actions in reaching their goals. Gamified apps should include social interaction, a sense of control, goal setting, and progress tracking, because these features motivate customers to hope for desired goals and engage more with the apps. This study finding implies that, instead of designing gamified apps that focus on compulsive use, practitioners should utilize hope as an alternative way to motivate customers to change their behaviors and achieve their objectives.

By utilizing the online reviews written on TripAdvisor platform, in their study Moro, Ramos, Esmerado, & Jalali (2019) tried to understand how each of the twelve gamification features used in TripAdvisor contributed to explaining review length and its sentiment score. In this study, three badge features – total number of badges, the passport badges and the explorer badges - were considered the most relevant ones, providing evidence of a relation between gamification features and traveler's behavior while writing reviews. In this study, it was found that visually appealing gamification features such as badges have a stronger effect on the review's length than simpler interaction counters.

By conducting research on online bookstore customers, in their study Hsu and Chen (2018) assessed the relationship among the experience of gamified marketing activities, perceived value (i.e., hedonic and utilitarian), satisfaction, brand love and desirable consumer behaviors. It was found that the experience of gamified marketing activities has a significant and positive impact on perceived hedonic and utilitarian value, which are in turn significantly influence satisfaction and brand love. Satisfaction, in turn, was found to have significantly positive impact on desirable consumer behaviors such as brand loyalty, positive word-of-mouth, and resistance to negative information. These research findings suggest that online retailers should incorporate gamification features to their marketing strategies if they want to better manage desirable consumer behavior.

Interesting results were obtained from gamification studies that assessed user behavior through Technology Acceptance Model (TAM). It was found that the more user perceives gamified apps to be useful and ease to use, the more satisfied he or she will become, thereby decreasing the tendency to quit

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

using such kinds of apps in the future (Huang et al., 2019). García-Jurado et al. (2019) suggested different type of users respond differently to gamified environment. They suggested that marketers should provide a fun interface to Millennials and a platform easier to use to the Generation X, for gamification to be successful. Rodrigues et al. (2016) applied TAM to better understand the adoption of gamified business applications. They assessed the influence of gamification on consumer behavior in online banking context. They explored the relationship between gamification, socialness, ease-of-use, usefulness, enjoyment, and intention to use a gamified e-banking app, and the corresponding business impact. In this context, socialness describes the phenomenon of users treating technology or technology interfaces, such as websites, as social actors and perceive that the interfaces to exhibit lifelike attributes associated with personality or emotions. Results of their study showed that when applied to e-banking platform, game design elements and social cues provide several positive outcomes, particularly in terms of the users' perceptions about application's usefulness, its ease-of-use and users' intention to use the given e-business app. They suggested that for customers most financial products and services are complex to understand; however, the use of gamification in such apps can help to make a serious application more attractive and easy to use for customers.

All of the above mentioned studies assessed the role of gamification in different fields. Results of these studies showed that gamification is not a simply gameful design but it can be a very powerful marketing tool which can be used to encourage engagement with a company's products and services. It also worth to mention that users do not respond to gamification strategies in the same way. Literature showed that different gamification techniques may have different end results in different types of users. Therefore, in order to get the desired effect individual differences should be taken into consideration by practitioners while designing and implementing such techniques.

CONCLUSION

In order to stay competitive companies are constantly looking for new means to stay a step ahead of their competitors. Gamification, the use of game mechanics in non-gaming applications, has become one of the promising means for managers. Gamification are being applied in various fields to bring intended behavioral outcome. For many businesses gamification is one the powerful technique to create desirable consumer behaviors such as increased engagement, higher retention, brand loyalty, positive word-of-mouth, etc. Well-designed gamification strategy attracts the target audience's attention to the company's products and services. While interacting with gamified interface, customers are drawn closer to the company and associate their enjoyment with company's products and services. It is also worth to mention that there is no one-size-fits all in the implementation process of gamification in e-commerce domain. Managers should tailor their gamified environments in such a way that they get more positive customer responses. What gamification tools and strategies are best for your customers mainly depends your particular business, products and audience. Gamification is possible to be found in many forms and it can include main building blocks of game in many different ways (Sailer et al., 2017). For gamification strategies to be successful it is very important for managers to understand the motivational effects of different gamification features on consumer behavior. Therefore, it is important that online business owners customize gamification techniques by considering the nature of their business and psychographic and behavioral characteristics of their customers.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Maybe today gamification have not yet reached its full potential yet but more and more managers have started to realize that they can implement this technique to change behaviors of consumers to achieve specific business outcomes. Originally, gamification was mostly about points, badges, and leaderboards, but it has changed to include additional game elements such as meaningful stories, avatars, virtual currency, personalization, tasks, social network features and many others. As game technologies improve, we will see transition and implementation of new game design elements in different non-game contexts. In the future we will also see gamification strategies built on top of virtual reality (VR) and augmented reality (AR) technologies which are already being applied in e-commerce field.

While gamification has brought lots of opportunities for business world, it has also brought ethical concerns and issues with itself. Gamification can be considered as a type of stealth marketing which is an act of advertising something to specific audience, without them realizing they are being marketed to. Stealth marketing is considered to be an unethical business practice by many. Currently, gamification is not formally regulated as a marketing practice. Researchers in this field has initiated discussions whether gamification should be regulated or monitored in some way (Thorpe and Roper, 2017; Marczewski, 2017). Gamification turns out to be unethical when the designer uses the psychology of users to manipulate them to do things which are not in their best interest (Marczewski, 2017). The use of random rewards to create addictive, gambling-like experiences that eventually lead certain users to be unable to exercise free will. As research developments advance and become more integrated into practice, more effective gamification will emerge and ethical issues will intensify even more (Thorpe and Roper, 2017). That is, as companies become more informed about the deep psychological mechanisms that underpin user engagement, they will have the opportunity of designing increasingly persuasive systems.

To sum up, gamification itself is not an unethical practice; however, the main emphasis here is on intention of the person designing and implementing it. Managers should develop such a system that will benefit both business itself and users equally. Gamified system should help online business owners to create a fun and engaging experience for their audience, which will eventually lead to a long-lasting and strong customer relationship. On the other side, such systems should help users to carry out their intended activities in an effective, efficient and at the same time entertaining manner but without being influenced by the system adversely. That is, gamified systems should help users, rather than causing harms to them.

KEY TERMS AND DEFINITIONS

B2C E-Commerce: Exchange of goods or services over the internet between businesses and customers.

Gamification: Use of game-design elements and game principles in non-game contexts.

Self-Determination Theory (SDT): A theory of motivation and personality that addresses three universal, innate and psychological needs which are competence, autonomy, and psychological relatedness.

Technology Acceptance Model (TAM): An information systems theory that models how individuals come to accept and use a technology.

ABSTRACT

Virtual reality presents exciting new opportunities for e-commerce with regard to the development of innovative shopping services. This article reports on an experimental investigation into the coordinated use of two human-computer interfaces (HCIs) for online shopping: virtual reality (VR) and webpages. We adopted the uses and gratification theory and technology acceptance model to determine how these HCIs affect online shopping intentions. Data from 98 participants revealed that entertainment value, informativeness, perceived ease-of-use, and perceived usefulness are the primary factors influencing the intention to use the VR HCI for online shopping ($p < 0.05$). Informativeness, perceived ease-of-use, and perceived usefulness are the main factors influencing the intention to use the webpage HCI for online shopping ($p < 0.05$). This study provides insights for businesses how to develop innovative shopping services using VR.

1. INTRODUCTION

The human-computer interfaces (HCIs) of online shopping platforms guide consumers in understanding the company's brand, products, prices, and services. Online shopping platforms that offer user-friendly and convenient HCIs bring customers significantly higher satisfaction (Jiang, Chan, Tan, & Chua,

2010; Visinescu, Sidorova, Jones, & Prybutok, 2015). Furthermore, when users become accustomed to a certain service method (e.g., the way an online platform HCI is operated), the habit will induce them to continue using this service and prevent them from easily changing to another service (Hsu, Chang, & Chuang, 2015; Chou & Hsu, 2016). To meet consumer needs (e.g., search for products quickly or compare prices), many online shopping platforms use text, photos, videos, and hyperlinks to construct their HCIs. However, such designs mainly provide 2D visuals and lack 3D elements for senses such as sight, hearing, and touch. As virtual reality (VR) technology matures, some online shopping platforms are converting their HCI designs from webpages to VR. For instance, Amazon plans to launch VR shopping services using PlayStation VR and HTC Vive, and Chinese conglomerate Alibaba was the first to launch VR shopping services in 2016. With the preliminary introduction of VR shopping into the market, understanding the acceptance and usage motives of consumers is crucial. Webpage shopping is already mature, so whether it is necessary to invest in VR shopping and whether VR can attract more consumers are both issues of concern for e-commerce businesses. In terms of HCI, webpages and VR obviously offer different shopping environments; webpages provide abundant shopping information swiftly, whereas VR provides experiences of near-real shopping environments. Specifically, VR makes use of sensory devices to immerse users in a simulated world. Specially designed headsets and glasses can be used for visual immersion, while hand-held devices provide tactile immersion. This capacity for complete immersion means that businesses are now able to create custom, unique experiences for their customers (Violante, Vezzetti, & Piazzolla, 2019). Previous research involving VR has focused on improving VR technology (Postma & Katz, 2015) or applied VR to medical treatment (Chen et al., 2016), education (North, North, & Coble, 2015), and games (Seibert & Shafer, 2018). Few studies have applied VR to shopping, so the influence of different HCIs (VR and webpages) on the shopping intentions of consumers is unclear. Furthermore, compared to physical stores, VR can offer richer stimuli to promote consumption without time or space constraints (e.g., product, brand, and music). As a result, many VR-related studies used the S(stimuli)-O(organism)-R(response) model to identify effective stimuli (Eroglu, Machleit, & Davis, 2003; Roschk, Loureiro, & Breitsohl, 2017). The SOR model holds that stimuli have a strong influence on the emotions and perceptual state of consumers (organism) and ultimately result in acceptance or avoidance in consumers (response) (e.g., decide to make a purchase or not). For example, Martínez-Navarro, Bigné, Guixeres, Alcañiz, and Torrecilla (2018) examined the external stimuli that influence consumers (e.g., brand or product) and the emotions or perceptual responses (e.g., discomfort felt in a VR experience) of consumers regarding VR (Martínez-Navarro et al. 2018), and Bigne, Llinares, and Torrecilla (2016) used eye trackers to analyze the shopping choices of consumers. Despite the good explanatory power of the SOR model, it focuses on what businesses can use to attract consumers and overlooks the fact that the psychological motives of the consumers themselves also have a strong influence on consumer decisions. In other words, even though the development of new technology (e.g., VR and augmented reality) is amazing and can offer consumers rich and diverse stimuli, the acceptance and psychological perceptions of consumers with regard to new technology are often crucial factors determining whether a business can profit. For these factors, the uses and gratifications (U&G) theory and the technology acceptance model (TAM) provide a reliable theoretical foundation. The former indicates that the psychological motives of consumers (e.g., entertainment, convenience, and informativeness) are important factors that impact consumer decisions, whereas the latter explains the acceptance of consumers with regard to new technology (e.g., VR shopping) from the perspective of perceived ease-of-use and perceived usefulness (see literature review for details). This study thus examined how HCIs (WEB/

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

VR) strengthen or weaken the online shopping intention of consumers using the uses and gratifications (U&G) theory and the technology acceptance model (TAM).

2. LITERATURE REVIEW

2.1 Uses and gratifications theory

Stemming from mass communication, the uses and gratifications (U&G) theory (Katz, Blumler, & Gurevitch, 1973) holds that different individuals choose and use communication media for varying purposes and further explains the psychological motive that prompts individuals to use media (e.g., search for information or entertainment). The U&G theory has been widely applied to study internet usage behavior and examine why and how consumers use certain online media. With social media as an example, researchers have used the U&G theory to discuss check-in intentions on Facebook and usage intentions on Instagram (Malik, Dhir, & Nieminen, 2016; Sheldon & Bryant, 2016). With the rapid development of online shopping, the psychological motives prompting consumers to choose certain online shopping platforms have become an important topic in e-commerce research. Existing research has found that entertainment (the subjective feelings that consumers derive from online media, such as pleasure, aesthetic enjoyment, emotional relaxation, and fun) (Hausman & Siekpe, 2009), convenience (the effort that online media designs can help consumers save in searching for, choosing, and using information) (Lim & Ting, 2012), and informativeness (the information that consumers can obtain when using online media) (Kaye & Johnson, 2004) are the main psychological motives behind the online media choices of consumers. These media include YouTube (Shao 2009), medical insurance websites (Cudmore et al. 2011), Twitter (Coursaris et al. 2010), and online games (Wu et al. 2010). As online shopping platforms share many of the same characteristics as these media (e.g., unrestricted by time or space, quick, easy to access), we assumed that entertainment, convenience, and informativeness are also the primary psychological motives behind the online shopping platform choices of consumers and used these three motives to examine the online shopping behavior of consumers. The main advantage of the U&G theory is its indication that individuals do not merely receive media information passively, as conventionally believed, but actively choose the media and information. Furthermore, the decisions of individuals are subject to the influence of various psychological factors. Despite these contributions, the U&G theory is limited primarily due to its neglect of the significant impact that the social conditions and environments surrounding individuals (e.g., different HCIs) may exert on individual decisions. This study therefore combined the U&G theory and the technology acceptance model (TAM) (described below) to make up for this shortcoming.

2.2 Technology Acceptance Model

The technology acceptance model (TAM) (Davis 1989) explains user behavior (such as whether a user accepts VR shopping) from the perspective of the user's inner cognition. TAM is currently one of the theory models most commonly used to examine user acceptance of information systems and has proven to be an effective tool in predicting willingness to use information system (Butt, Tabassam, Chaudhry, & Nusair, 2016).TAM holds that attitude towards using is an important factor that determines the behavioral intention of users, and two psychological factors influence attitude towards using: perceived usefulness

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(PU) and perceived ease of use (PEOU). TAM holds that when people have not had the experience of using a technology or do not have an in-depth understanding of a technology, they will have a psychological feeling called perception. PU is defined as the degree to which a user perceives that adopting a technology will help him or her increase work efficiency and productivity, and greater PU means that the user will be more willing to adopt the technology. PEOU refers to the amount of effort that the user believes will be needed to use the technology. Effort is a limited resource, so people will naturally expend their effort on activities that use the fewest resources (McNeil, Odell, & Tseng, 1991).As a result, Davis (1989) indicated that if an information system gives users the perception that it is easy to use, then users will be significantly more willing to use it. The VR and webpage online shopping platforms discussed in this study are both information systems. Thus, we can use TAM to clearly understand the usage intentions of users toward VR shopping and webpage shopping systems and provide reference for e-commerce decisions. Finally, despite the widespread use of TAM to explain the acceptance of various information technologies, TAM is limited in that it assumes that users adopt an information technology because they feel that the technology can benefit themselves and help them complete their work (i.e., pragmatism). This assumption disregards the influence of factors such as emotions and peers on user decisions. For this reason, later studies proposed more complex models (e.g., TAM 2 and TAM 3). Nevertheless, we took into account the limitations of actually executing our VR shopping experiment and questionnaire survey (Please see research limitations) and thus only adopted the two core constructs of TAM, PU and PEOU, for this study.

2.3 Human computer interface of online shopping platform

Online shopping involves a virtual shopping environment using an HCI (e.g., a webpage) that enables consumers to search for information about products and services and place orders (M. Kim & Lennon, 2000).An HCI is the medium of information exchange between humans and machines (e.g., an online shopping platform computer). Humans can use the interface to input commands into machines (e.g., a mouse, a keyboard, hand gestures), and then the machines use information technology to read and respond to the commands (e.g., artificial intelligence or natural language processing) (Lazar, Feng, & Hochheiser, 2017).HCIs contain three aspects: information design, interaction design, and sensorial design (Shedroff, 2001).The webpage designs of online shopping platforms are hampered in that their sensorial design is limited by the hardware; they mainly provide 2D visuals and are relatively lacking in 3D elements for senses such as sight, hearing, and touch. The development of VR removes this limitation. VR uses computers to simulate a 3D virtual environment, which gives users an immersive experience. The computer devices generally include a screen, sensors, and a computer (Serrano, Baños, & Botella, 2016). VR can simulate real shopping venues and give consumers richer and more interesting shopping experiences. As a result, many corporations are beginning to develop VR shopping services. Researchers have compared the shopping behavior of consumers in 3D VR and in physical stores. The results indicated that the shopping behaviors of consumers in the two environments are not the same; consumers spend significantly more money in VR than in physical stores but purchase similar products (van Herpen, van den Broek, van Trijp, & Yu, 2016). Researchers have also analyzed the psychological feelings that VR shopping and webpage shopping bring to consumers. The results revealed that VR shopping gave customers significantly greater satisfaction in terms of convenience, enjoyment, and quality guarantee (Lee & Chung, 2008).Although a small number of studies have been conducted on VR shopping, many of the early studies used desktop computer screens, stereo headphones, and inertial sensors to simulate

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

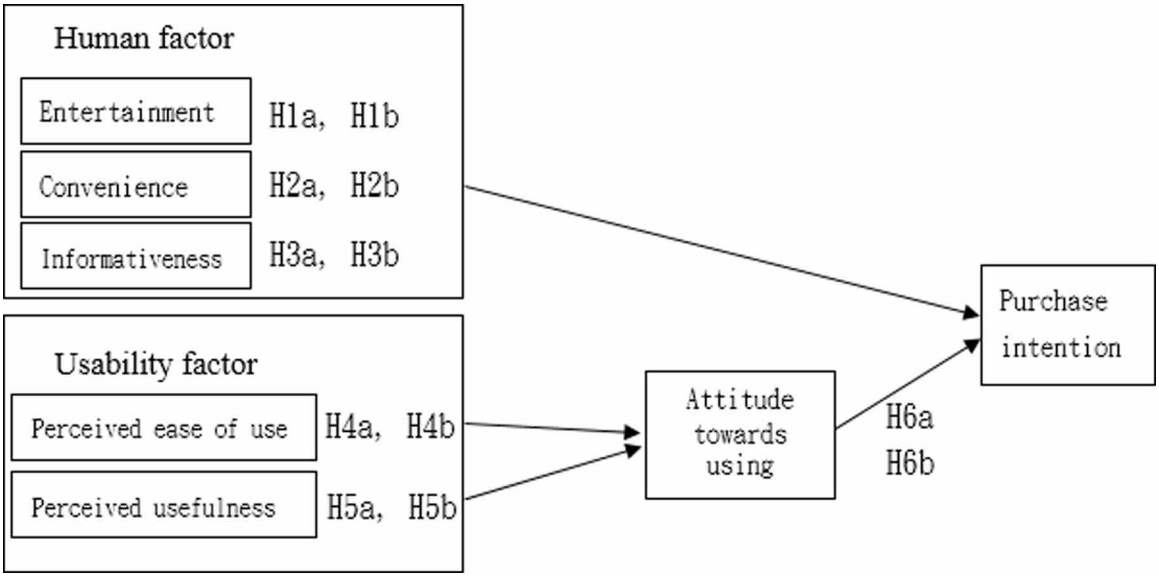
3D environments, which are significantly different from the latest VR headsets (e.g., PlayStation VR and Google Cardboard). Thus, it is still unclear whether consumers can accept shopping with VR headsets, which is what this study set out to establish. In addition to online shopping platforms, VR has also been used in physical stores. For example, IKEA uses VR to help customers design a customized kitchen. Customers enter the virtual kitchen through VR goggles and can change the paint colors, furniture, or lighting. As they walk around the room to see things from different angles, they can also add accessories and rearrange furniture. Car company Lexus, and Makeup company NARS have also developed specific VR applications. Despite this spread of VR technology, VR online shopping is the fastest-growing sector among VR applications, which is why we selected it as the focus of this study.

3. METHODOLOGY

3.1 Research model

This study constructed a research model combining the U&G theory and TAM (Figure 1) and used this model to examine how HCIs (WEB/VR) strengthen or weaken the online shopping intention of users. Specifically, this study focuses on two HCI-related constructs: human factors and usability factors. Human factors refer to user responses to the HCI, including entertainment value, convenience, and informativeness; usability refers to how a user perceives and interacts with an online shopping platform through the HCI. Below we provide detailed definitions of these two constructs.

Figure 1. Research model



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.2 Research Hypothesis

(1) Entertainment refers to the subjective feelings that consumers derive from shopping on e-commerce platforms, such as pleasure, aesthetic enjoyment, emotional relaxation, and fun. Past studies using the U&G theory have demonstrated that entertainment is a crucial psychological factor for users. For instance, Shu (2011)) stated that fun is a crucial factor that attracts consumers to participate in group buying; Hausman and Siekpe (2009)) discovered that entertainment exerts a significant impact on the online purchase and repurchase intentions of consumers. Furthermore, VR shopping is a novel model of shopping compared to web shopping, and the immersive 3D interactive experiences that it offers can significantly enhance the feeling of pleasure that consumers can derive while shopping.

(2) Convenience refers to the time and effort that an e-commerce platform design can help consumers save in shopping and searching for information, thereby enabling consumers to achieve their objectives more easily. Research has shown that when consumers perceive greater convenience in a company's services, they are more willing to continue their patronage (Chiu, Wang, Fang, & Huang, 2014; Ozturk, Bilgihan, Nusair, & Okumus, 2016). In other words, the most important thing for companies wanting to keep their customers is to provide convenient services, and HCIs are a crucial factor that influences the amount of convenience that consumers perceive (Benbasat, 2014). With VR shopping, consumers do not have to go to physical stores in person and can purchase any product they want virtually anytime, anywhere. This form of shopping should be able to effectively enhance the amount of convenience perceived by consumers.

(3) Informativeness refers to the information that consumers can obtain regarding products and services when using e-commerce platforms (e.g., prices and discounts). Research has shown that the quality of information on shopping websites can directly impact the views that consumers have with regard to the products and services of the company/brand, which constitute the attitude that consumers have towards the company (Zia, 2009).The results of many studies indicate that when the information provided on a shopping website satisfies consumer needs to a greater degree, then the purchase intentions of the consumers will also be higher (Matzler, Würtele, & Renzl, 2006). The VR shopping model allows consumers to quickly and easily find the products they want and see all types of product information (e.g., price, similar products, price comparisons, and customer reviews). This form of shopping should therefore be able to effectively increase the degree of informativeness that consumers perceive.

(4) Perceived usefulness (PU) is the degree to which a user perceives that using an HCI will help him or her increase work efficiency (e.g., shopping more quickly). If an HCI is perceived to be more useful to a user, then said user will be more willing to use it.

(5) Perceived ease of use (PEOU) refers to how easy an HCI is to use as perceived by a user. A user will have a more positive attitude toward an HCI that is easier to use. Generally speaking, HCIs include information design, interaction design, and sensorial design. With VR shopping, VR simulations of actual shopping scenarios can provide consumers with more interesting shopping experiences. Such immersive experiences should be able to effectively enhance the PU and PEOU of consumers.

(6) Attitude towards using is the positive or negative rating that a user gives to the HCI of an online shopping platform. A consumer that has a more positive attitude towards using the online shopping platform will also have greater purchase intention.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(7) Purchase intention is the likelihood that a consumer will purchase a product or a service. A greater purchase intention means that the probability of the consumer making a purchase is higher (Pappas, Kourouthanassis, Giannakos, & Chrissikopoulos, 2016).

Based on the discussion above, we put forward our hypotheses of this study, H1-H6:

H1a: An entertaining VR shopping interface design has a positive influence on the purchase intention of consumers.
H1b: An entertaining web shopping interface design has a positive influence on the purchase intention of consumers.
H2a: A convenient VR shopping interface design has a positive influence on the purchase intention of consumers.
H2b: A convenient web shopping interface design has a positive influence on the purchase intention of consumers.
H3a: An informative VR shopping interface design has a positive influence on the purchase intention of consumers.
H3b: An informative web shopping interface design has a positive influence on the purchase intention of consumers.
H4a: PEOU has a positive influence on the attitude towards using a VR shopping interface.
H4a: PEOU has a positive influence on the attitude towards using a web shopping interface.
H5a: PU has a positive influence on the attitude towards using a VR shopping interface.
H5b: PU has a positive influence on the attitude towards using a web shopping interface.
H6a: The attitude towards using a VR shopping interface has a positive influence on purchase intention.
H6b: The attitude towards using a web shopping interface has a positive influence on purchase intention.

3.3 Participants

The samples for the study comprised students from a national university in Taiwan. The selection of full-time students provided effective control for some important confounding factors such as technology acceptance, social roles, education level, and financial conditions. Cluster sampling was used to select participants from subject classes. A broad representation of the student population was obtained by selecting medium-size classes (20–50 students) from a wide range of courses in different departments and disciplines. A total of 10 classes were sampled. All students in the selected classes were invited to participate in the surveys. A total of 100 students agreed to participate in this survey. Inspection of the resulting questionnaires revealed 2 invalid (incomplete) questionnaires, so we recovered a total of 98 valid questionnaires. Among the participants, 50% were male (n = 49), and 50% were female (n = 49). With regard to their educational backgrounds, 68% were pursing their master's degree or higher (n = 67), while 32% were undergraduates (n = 31). All of the participants fell between 21 and 25 years in age (n = 98, 100%). Furthermore, 45% of the participants had never used VR before (n = 44), while the remaining 55% had used VR at least once (n = 54). Finally, 98% had experience in online shopping (n = 96).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

3.4 Experiment process

The experiment process comprised two phases: In the first phase, shopping experiment: The participants used Google Cardboard paired with a VR app (Supermercado VR Cardboard) (Roig, 2018) for VR shopping (Fig. 2). Next, the participants browsed an online shopping website (instacart.com) using a MacBook Air 13 for webpage shopping. In order for the participants to experience all of the functions of the shopping platforms, we asked the participants to perform the following steps: (a) purchase meat, drink, and milk products, with at least 2 items for each category, one of which has the lowest price in the category, (b) cancel pre-selected products in their shopping cart until their total is below USD 10, and (c) check out. The steps above ensure that the participants could experience all functions related to searching for products, comparing prices, canceling pre-selected products, and checking out. With these, the participants could evaluate the entertainment, convenience, informativeness, PU, and PEOU of the shopping platforms. In the second phase, after shopping, the participants completed a questionnaire to describe their experience. The questionnaire was designed based on the U&G theory and TAM and was refined in consultation with two experts in the field. It comprised 35 question items (Appendix 2) measured on a five-point Likert scale ranging from strong disagreement (1 point) to strong agreement (5 points). Furthermore, the questionnaire was also pre-tested on a sample of 20 students who were randomly selected. The completed questionnaires were then examined to identify major issues that needed amendment. Some questions were therefore rephrased to ensure the appropriateness of the questionnaire for the target respondents.

3.5 Questionnaire reliability

We used Cronbach's α to test the reliability of the questionnaire. The results showed that the Cronbach's α values of the various constructs of the questionnaire ranged from 0.72 to 0.91, thereby indicating good reliability. This means that the results can faithfully reflect the thoughts and opinions of the participants. The respective Cronbach's α values for the VR and webpage HCIs in the various constructs of the questionnaire were as follows: 0.85 and 0.77 in entertainment, 0.80 and 0.77 in convenience, 0.82 and 0.80 in informativeness, 0.85 and 0.86 in PEOU, 0.84 and 0.77 in PU, 0.91 and 0.81 in attitude, and 0.88 and 0.80 in purchase intention.

3.6 Data analysis

We used SPSS 21 for data analysis, t-tests to examine the differences among independent variables, and multiple regression analysis to test our hypotheses. Significance was tested as the 0.05 level. To ensure that our results are robust, we conducted a multicollinearity test to assess the degree of correlation among the independent variables in the research model. The results of the multicollinearity test (Appendix 2) revealed that the VIF (Variance Inflation Factor) values of the independent variables were all much smaller than the allowed range of 10 (Hair, 2006). Thus, no evidence could be established for the existence of collinearity among the variables.

Figure 2. Virtual reality environment

VR device: Google Cardboard	Snapshot of VR app: Supermercado VR Cardboard (Roig, 2018)

3.7 Common Method Bias Assessment

As all the data in this study were self-reported and collected from individual respondents, common method bias was possible. Therefore, we used the analytical procedure suggested Liang, Saraf, Hu, & Xue (2007) to assess the severity of common method bias in these data. First, we introduced a new factor named 'method' to the model, and the common method factor indicators included all the principal constructs' indicators. Second, we calculated each indicator's variances substantively explained by the principal construct and by the method. Then, we examined the statistical significance of factor loadings of the method factor, and compared the variances of each observed indicator explained by its substantive construct and the method factor. The results (Appendix 3) show that the average substantively explained variance of the indicators is 0.84, while the average method-based variance is 0.012. The ratio of substantive variance to method variance is about 60:1. These results indicated that the method did not contribute substantially to the variance in the indicators and thus common method bias was unlikely to be a serious problem in this study.

4. RESULTS AND DISCUSSION

4.1 Difference test

4.1.1 Web and VR HCIs

Table 1 presents the satisfaction analysis results of the participants with regard to the different HCIs (VR/Web). In terms of the psychological motive factors (entertainment, convenience, and informativeness), the participants were only significantly more satisfied with the VR HCI than with the web HCI in the entertainment aspect (i.e., VR 3.94: web 3.43). In the other psychological motive factors, the VR HCI derived lower satisfaction than the web HCI, particularly in informativeness (i.e., VR 3.08: web 3.91). This shows that VR has the advantage in bringing participants pleasure, aesthetic enjoyment, and fun (entertainment) with its 3D shopping environment but is in need of improvement in the other psychological motive factors to increase purchase intention. This result supports the finding derived by (Hausman & Siekpe, 2009) in that entertainment has a significant impact on the online purchase intention of consumers.

Table 1. Analysis of participant satisfaction in shopping with different HCIs

Construct	Mean satisfaction (1-5 points, 5=most satisfied)		t value	P value
	VR	WEB		
Entertainment	3.94	3.43	5.40	0.000*
Convenience	3.49	4.22	-7.85	0.000*
Informativeness	3.08	3.91	-7.91	0.000*
PEOU	3.89	4.36	-5.31	0.000*
PU	3.40	4.04	-6.37	0.000*
Attitude towards using	3.53	3.97	-4.24	0.000*
Purchase intention	3.25	3.93	-6.19	0.000*

*indicate $p < 0.05$

Observation of PEOU and PU revealed that the participants were significantly less satisfied with the VR HCI than with the web HCI (i.e., VR 3.40: web 4.04). To understand the cause of this, we examined the questionnaire data and found that question item PEOU 1 (this operation method was easy from the very beginning.) had the lowest mean satisfaction score (3.46) among the five question items in the PEOU construct, while question item PEOU 5 (getting familiar with the VR HCI was not difficult.) had the highest mean satisfaction score (4.12). Based on this result, we inferred that it took the participants some time to get accustomed to the VR HCI, and only when they were accustomed did their satisfaction increase. Furthermore, a portion of the participants ($n = 15$) reported that they experienced dizziness while using VR. Researchers have explained that this is because the VR equipment makes the eyes feel that the body is moving, but the body is not actually moving, and this difference in synchronization between the two causes dizziness (Newbutt, Sung, Kuo, & Leahy, 2017). This may also be one of the causes of lower satisfaction with VR shopping. The issue of VR has also been mentioned in other studies

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Sayyad, Sen, & Höllerer, 2017), so companies developing VR shopping should first solve this problem and let more consumers experience VR shopping so that more consumers will accept VR shopping. Past research has indicated that once users adapt to new technology, their usage intention will indeed increase (Karahanna, Straub, & Chervany, 1999).

4.1.2 Gender

T-test results revealed no significant differences between the mean satisfaction of the male and female participants in the various constructs ($p < 0.05$). However, the mean satisfaction of the female participants was slightly higher than that of the male participants (male: 3.74, female: 3.94). Past research has shown that males place particular emphasis on not needing to wait and swift services (Mortimer & Clarke, 2011). In VR shopping, the interface design meant that it took more time to select products and check out, so this may be the cause of lower satisfaction among the male participants in this study. Thus, e-commerce businesses should enhance the convenience of VR shopping and shorten operation time. Another strategy that might benefit operations is focusing on female consumers during the initial launch of VR shopping.

4.1.3 Usage experience of VR

This study investigated whether the VR experience of participants influenced their satisfaction in VR shopping. The respective mean satisfaction scores given by participants with and without VR experience in the various constructs were as follows: 3.85 and 4.04 in entertainment, 3.40 and 3.58 in convenience, 2.94 and 3.24 in informativeness, 3.92 and 3.85 in PEOU, 3.32 and 3.48 in PU, 3.41 and 3.67 in attitude, and 3.14 and 3.37 in purchase intention. On the whole, the mean satisfaction of the participants was higher than a scale mean (3.00) regardless of VR experience. The mean satisfaction of the participants with no VR experience was slightly higher that of the participants with VR experience. However, t-test results indicated no significant differences between the mean satisfaction of the two groups of participants ($p<0.05$). This result has two major implications: (1) the participants with VR experience may have compared their VR shopping experience with past experiences, so their satisfaction standards may have been higher; (2) most of the participants with VR experience study had played VR games before, so they got the hang of VR shopping very quickly. In contrast, most of the participants with no VR experience were fairly young (between 18 and 25 years of age), so they became accustomed to VR operations very quickly and their lack of previous experience did not affect their shopping satisfaction. Based on the results above, we suggest that e-commerce businesses promote VR shopping to young consumers because they have greater adaptability and are more likely to accept VR shopping. However, they will also be more demanding with regard to the HCIs of VR shopping, which may mean that a VR HCI design similar to that in a VR game will gain more favor.

4.2 Hypothesis testing

We used multiple regression analysis to test the research model (Figure 1). Table 2 displays the test results, which we discuss by category below.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Hypothesis testing results

Hypothesis	Independent variable	Standardized β coefficient		Adjusted R^2		Dependent variable	Results	
		VR(a)	WEB(b)	VR(a)	WEB(b)		VR(a)	WEB(b)
H1a, H1b	Entertainment	0.208**	0.031	0.513	0.349	Purchase intention	Supported	Not supported
H2a, H2b	Convenience	0.130	0.201				Not supported	Not supported
H3a, H3b	Informativeness	0.521***	0.461***				Supported	Supported
H4a, H4b	PEOU	0.231**	0.178*	0.544	0.657	Attitude towards using	Supported	Supported
H5a, H5b	PU	0.601***	0.689***				Supported	Supported
H6a, H6b	Attitude towards using	0.801***	0.502***	0.638	0.244	Purchase intention	Supported	Supported

(*, **, and *** indicate $p < 0.05$, $p < 0.01$, $p < 0.001$, respectively.)

4.3 VR shopping

As shown in Table 2, H1a, H3a, H4a, H5a, and H6a all reached the level of significance, while H2a did not. This shows that in VR shopping, entertainment ($\beta = 0.208$, $p < 0.05$) and informativeness ($\beta = 0.521$, $p < 0.001$) both had significant impact on the purchase intention of the participants ($R^2 = 0.513$); PEOU ($\beta = 0.231$, $p < 0.01$) and PU ($\beta = 0.601$, $p < 0.001$) had significant influence on the attitude towards using ($R^2 = 0.544$), and attitude towards using ($\beta = 0.801$, $p < 0.001$) had significant influence on the purchase intention ($R^2 = 0.638$). As VR online shopping emphasizes immersion, this study examines the extent to which the level of immersion and sense of presence impact users. These results show that informativeness was the most important factor influencing the participants in VR shopping, followed by entertainment. Thus, when e-commerce businesses are developing VR shopping, they should ensure that the HCI design can provide adequate information on products and services. Although VR shopping offers a high degree of entertainment, what satisfies the needs of participants whose goal is buying things is finding the product information that they want. To understand why H2a (convenience) was not supported, we examined the questionnaire data of the convenience construct. The results indicate that the mean satisfaction scores of question items C2 (Using this VR while shopping allows me to find what I want quickly.) and C4 (The process of using VR shopping was smooth for me.) were only 3.00 and lower than those of the other question items. This may be because the VR equipment used in this study was not accompanied by a hand remote, thereby requiring the participants to gaze at products on the screen image for 1 to 2 sec to select them. This hindrance in operations is probably what caused the poor satisfaction with convenience. Furthermore, PEOU and PU both wielded a significant and positive influence on attitude towards using, which means that the more users perceived VR operations to be easy and helpful in completing their tasks, the more positive their attitude towards VR shopping was. Finally, according to H6a, e-commerce businesses looking to increase purchase intentions in users should focus on purchase intentions. In other words, they should enable users to feel happy and relaxed in the shopping environment and arouse their curiosity.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.4 Web shopping

As shown in Table 2, H3b, H4b, H5b, and H6b all reached the level of significance, while H1b and H2b did not. This shows that in web shopping, only informativeness ($\beta = 0.461$, $p < 0.001$) had a significant impact on the purchase intention of the participants ($R^2 = 0.349$); PEOU ($\beta = 0.178$, $p < 0.05$) and PU ($\beta = 0.689$, $p < 0.001$) had significant influence on attitude towards using ($R^2 = 0.657$), and attitude towards using ($\beta = 0.502$, $p < 0.001$) had significant influence on the purchase intention ($R^2 = 0.244$). These results show that informativeness was the most important factor influencing the participants in web shopping. In other words, regardless of the HCI, the main concern of the participants was still whether the HCI provided adequate product information and made it convenient for them to search for and compare the products they want. Furthermore, the development of web shopping HCIs is mature, and as they are much more common than VR shopping, so their lack of novelty may have resulted in entertainment having no significant influence on the web purchase intentions of the participant. In another aspect, most of the participants were already used to the conveniences of web shopping and thus probably considered convenience to be a basic requirement of web shopping. So this attitude may have resulted in convenience having no significant influence on the experiment results. The results of H4b, H5b, and H6b were identical to those associated with VR shopping, which tells us that when companies are developing HCIs for shopping, PEOU and PU are crucial factors.

5. CONCLUSION

This study employed the U&G theory and TAM to examine how different HCIs influence the purchase intention of consumers. Below, we summarize the key findings and practical implications of this explorative study.

5.1 Psychological motive factors of consumers

Based on the three psychological motive factors of the U&G theory (entertainment, convenience, and informativeness), we discovered that informativeness has the greatest influence in both methods of operation. In other words, consumers place lot of emphasis on price comparison and product information comparison when they are shopping. For this reason, companies developing online shopping platforms must pay special attention to informativeness. In contrast, entertainment only had significant influence on the VR HCI. For most of the participants, VR was a novelty that they had not experienced before. This curiosity led to a positive influence on purchase intention. Finally, convenience did not have a significant influence on purchase intention in either shopping scenario. However, the questionnaire results showed that the mean satisfaction scores for convenience were higher than the mean score for both VR and web shopping. This may indicate that while both HCIs already offer moderate to high levels of convenience, the participants may think that convenience is a basic service requirement of shopping platforms, and thus it had a less significant influence on participant intention.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

5.2 HCI factors

The two HCI factors of TAM (PEOU and PU) had significant and positive influence on the attitude towards using of the participants in both the VR and web HCIs, particularly PU. In other words, consumers attach a lot of importance to whether shopping platform HCIs can display information in a simple manner and help them complete their shopping quickly. Users derive more satisfaction from HCIs that are simpler, more efficient, and easier to understand. In addition, we also found that the attitude of users towards using shopping platform HCIs (i.e., positive or negative ratings) has significant influence on their purchase intention. As a result, companies must carefully design HCIs and ensure that they meet the needs and preferences of their target customers so as to effectively enhance the purchase intention of consumers.

5.3 Comparison of VR and web HCIs

(1) HCI: The HCI exerts a significant influence on the usage motives (entertainment, convenience, and informativeness) and purchase intentions of consumers. Both the VR and web HCIs in our experiment significantly enhanced the purchase intentions of consumers. The entertainment aspect of the VR HCI increased the purchase intention of users more significantly than that of the web HCI, while the informativeness aspect of the web HCI increased the purchase intention of users more significantly than that of the VR HCI. (2) Personal backgrounds of the participants: The participants displayed no significant differences with regard to gender, VR usage experience, and educational background, which means that these personal background factors do not influence the purchase intention of consumers. It is worth mentioning that the male participants mostly spent less time completing the tasks than the female participants. Furthermore, the undergraduates also mostly spent less time completing the tasks than the postgraduates.

5.4 Research contributions and practical implications

The main contributions of this study are as follows: (1) theoretical aspect: This study applied the U&G theory to study online shopping and furthers understanding on how HCIs (WEB/VR) strengthen or weaken the online shopping intention of users; (2) practical implications: Online shopping companies can use the results of this study to formulate differential marketing strategies, and make improvements in the important factors that influence the purchase intention of consumers. Specifically, online shopping companies can refer to the following suggestions: (a) the results of this study indicate that informativeness is a crucial factor of purchase intention, so developing companies can focus on this aspect, such as enabling consumers to compare prices and products or offering any other functions that allow consumers to understand and search for products; (b) compared to Website shopping and physical stores, VR can offer a higher degree of entertainment, which has been shown to be a key factor of purchase intention in our study. Accordingly, companies can use VR to develop entertaining shopping scenarios (e.g., shopping game, monopoly, lottery) to enhance consumers' intention to purchase; (c) PEOU and PU both wield influence on the purchase intention of users, so companies should make shopping HCI designs simple and easy to use (e.g., easy to operate, easy to learn, and less time-consuming); For example, VR shopping companies can use a combination of VR glasses with handheld devices to make it easier for consumers to click on virtual items; (d) according to literature and the results of this study, the purchase intentions

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of males and females vary, so companies developing online shopping platforms can develop different interfaces for different genders, such as a simple interface that enables quick shopping for males and an aesthetic and entertaining interface for females; (e) the participants of the experiment in this study were mainly between the ages of 16 and 25. Individuals within this age range are more accepting of VR and display more positive attitude toward VR; thus, companies can promote VR shopping to consumers at this age first. (3) Academic literature: VR shopping is currently in the initial introduction period, so there is limited foreign and domestic literature regarding this topic. So far, existing studies involving VR have focused on identifying the external stimuli that influence consumers (e.g., brand or product) and the emotions or perceptual responses (e.g., discomfort felt in a VR experience) of consumers regarding VR (Martínez-Navarro et al. 2018) or used eye trackers to analyze the shopping choices of consumers (Bigne et al., 2016). However, they disregarded the influence of HCIs and the internal psychological motives of consumers on their purchase decisions. This study thus has three primary contributions for VR shopping: (a) this study revealed the influence of the psychological motives of consumers, particularly informativeness and entertainment, on consumer willingness to engage in VR shopping; (b) this study demonstrated that HCIs (i.e., PU and PEOU) exert a positive impact on consumer attitude towards using, with PU having a particularly significant impact; (c) this study compared the influence of different HCIs (VR and websites) on consumer attitude towards using so that companies can use one or a mix of both to attract consumers. (4) Methodological implications: (a) We recommend using a combination of VR glasses with handheld devices for this type of VR shopping experiment. Several of our participants suggested that it is more convenient and intuitive to click on a virtual item with a handheld device than with eye contact. (b) We also recommend simplifying the experimental design in order to increase willingness to participate as well as the accuracy of collected data. Some of our participants suggested shortening the experiment time to a maximum of 30 minutes.

5.5 Research limitations and future research

(1) The participants of this study were mainly undergraduates and postgraduates between the ages of 16 and 25, so the results of this study can only be applied to consumers of similar age and educational background. Future studies can increase the sample range, such as including participants of younger or older ages to understand the views of different age groups toward online shopping and ensure that the study results are more circumspect. (2) This study used Google Cardboard (GC) for VR shopping. At present, GC offers wider compatibility and is easier to obtain. However, it caused dizziness in some of the participants, and the lack of a hand remote made using GC less convenient. These reasons may have caused the poorer satisfaction with VR shopping. (3) The VR software in this study was mainly for online shopping, so the results of this study may not be applicable to other non-shopping software (e.g., games and photography). (4) At the time of this study, no VR shopping software designed using images from real physical stores was available for our experiment. Due to time and labor constraints, we used Supermercado VR cardboard to conduct our experiments. This program presents animated shopping scenarios that are fairly close to real shopping scenarios but are still computer-generated scenarios. We recommend real-world VR shopping software or more complex VR system (e.g., HTC VIVE) for future studies for better results. (5) This study merely investigated the influence of entertainment, convenience, and informativeness on the online purchase intentions of consumers. Future studies can include more factors that influence purchase intention to ensure that the study results are more circumspect. (6) Aside

from being applied to online shopping platforms, VR is also becoming common in other industries and physical stores. However, VR online shopping and the VR services of physical stores basically enable users to enter a virtual space via a VR device to experience the products and services that are offered, so they are essentially quite similar. This study is mainly a report regarding VR online shopping, and future studies can test this model on VR services in other industries and physical stores to explore any differences in user acceptance. (7) This study combined the U&G theory and TAM model to develop a questionnaire containing 7 constructs and 36 question items. In our shopping experiment, the participants used the VR device Google Cardboard to perform a series of shopping actions and then repeat the shopping actions on an online shopping website. At the end of the experiment, they filled out our questionnaire. Pre-test results indicated that on average, participants needed more than 30 minutes to complete the experiment and the questionnaire, which is significantly longer than the 15-20 minutes recommended by past studies. To prevent people from being unwilling to participate due to the experiment being too complex or the questionnaire being too long, we only adopted the two core constructs of TAM (PU and PEOU) and three crucial psychological motives (entertainment, convenience, and informativeness) to ensure that we could recruit enough participants and collect high-quality data. We suggest that future studies employ TAM2 and TAM 3 or include more psychological motives or control variables for more complete results. (8) The samples of this study were obtained in Taiwan; the results of this study may differ from those that would have been obtained had this study been conducted in another country due to differences in culture and consumption habits. We suggest that researchers apply the model constructed in this study to different countries or industries (e.g., health care, education, or gaming) to understand how users in different settings may differ.

APPENDIX

Appendix 1. Questionnaire

Study construct	Question item	Reference
Entertainment	1. Using this operation method (VR/Web) makes me feel happy while shopping. 2. Using this operation method (VR/Web) makes me feel relaxed while shopping. 3. Using this operation method (VR/Web) makes me have fun while shopping. 4. I enjoy using this operation method (VR/Web) while shopping. 5. Using this operation method (VR/Web) while shopping satisfies my entertainment needs.	Kaye & Johnson, 2004; Hausman & Siekpe, 2009
Convenience	1. Using this operation method (VR/Web) while shopping is convenient and quick (for example, I do not have to get through crowds to get what I want). 2. Using this operation method (VR/Web) while shopping allows me to find what I want quickly. 3. This operation method (VR/Web) is simple and does not require too many unnecessary steps. 4. The process of using this operation method (VR/Web) was smooth for me. 5. I can solve any problems I encounter while using this operation method (VR/Web) by myself.	Kaye & Johnson, 2004; Kim & Johnson, 2013
Informativeness	1. Using this operation method (VR/Web) while shopping makes it easy to compare prices. 2. Using this operation method (VR/Web) while shopping helps me make purchase decisions. 3. Using this operation method (VR/Web) while shopping helps me compare products. 4. Using this operation method (VR/Web) while shopping increases my shopping efficiency. 5. Using this operation method (VR/Web) while shopping provides me with the information I am interested in.	Matzler et al., 2006; Lim & Ting, 2012
Perceived ease of use	1. This operation method (VR/Web) was easy from the very beginning. 2. This operation method (VR/Web) was easy to learn. 3. Completing the purchase process was easy. 4. The interactive experience of this operation method (VR/Web) was clear and user-friendly. 5. Getting familiar with this operation method (VR/Web) was not difficult.	Davis, Bagozzi, & Warshaw, 1989
Perceived usefulness	1. Using this operation method (VR/Web) took me less time and effort. 2. Using this operation method (VR/Web) enhanced shopping quality for me. 3. Using this operation method (VR/Web) allows me to complete my shopping more easily. 4. Using this operation method (VR/Web) allows me to obtain the information I want more easily. 5. This operation method (VR/Web) is very useful for shopping.	Davis et al., 1989
Attitude towards using	1. Using this operation method (VR/Web) makes me feel comfortable. 2. I like using this operation method (VR/Web) to purchase things that I need. 3. I like using this operation method (VR/Web) to search for product information on the shopping website. 4. I think using this operation method (VR/Web) for shopping is a good idea. 5. Using this operation method (VR/Web) makes me feel relaxed. 6. Using this operation method (VR/Web) makes me feel happy.	Lim & Ting, 2012; Yoon, 2016
Purchase intention	1. I intend to continue using this operation method (VR/Web) for shopping. 2. When I want to buy a specific product, I will search for a shopping website that has this operation method (VR/Web). 3. Shopping websites with this operation method (VR/Web) will be my first choice when I shop for products. 4. I may purchase products from shopping websites with this operation method (VR/Web). 5. I will recommend this operation method (VR/Web) to my friends and family.	Lim & Ting, 2012; Yoon, 2016

Chapter 40
Can Virtual Customer Service Agents Improve Consumers' Online Experiences?
The Role of Hedonic Dimensions

ABSTRACT

This chapter focuses on the navigation experience in ecommerce. The authors address the impact of a number of hedonic dimensions, specifically perceived visual attractiveness, perceived enjoyment, and sociability, in consumers' online experiences. They develop and test a research model explaining how these factors affect trust, satisfaction, and ultimately, website loyalty. Findings from a survey carried out with 132 users of an airline's website, which displays a virtual customer service agent, support the model proposed. Specifically, results confirm that enriching consumers' sensory experiences online through aesthetics, an enjoyable experience, and a social interaction interface positively affects trust, satisfaction, and subsequently, loyalty.

INTRODUCTION

Companies continuously search for strategies to improve their online interfaces and websites (Pappas *et al.*, 2017), hence improving the quality of online navigation for users. Interface design improvement, in particular through web personalization, has an enormous potential for making online commerce more like real world shopping, enriching consumers' shopping experiences online (Cyr *et al.*, 2006; Papadopoulou, 2007; Pappas *et al.*, 2017) as well as increasing trust, satisfaction, and loyalty (Pengnate & Sarathy, 2017).

Whilst in real life the shopping process can be considered a social event, ecommerce applications need to be able to replicate and integrate elements from the social context into their online context (Papadopoulou, 2007). Childers *et al.* (2002) argued that an important motivation for engaging in online retail shopping is the hedonic function of the website. In fact, the perceived sensory experience, derived from the aesthetics of the site which can render the navigating experience more enjoyable, has been pointed as an important strategy to enrich and facilitate navigation (Childers *et al.*, 2002; Lavie & Tractinsky 2004; Van der Heijden 2003; Robins & Holmes 2008; Cyr *et al.*, 2006).

The use of virtual customer-service agents has been noted to allow consumers to personalize their experience online (Alves & Soares, 2014; Moon *et al.*, 2013; Verhagen *et al*., 2014) by improving the perceived sociability and by rendering navigation experience more enjoyable for consumers (Wang & Fodness, 2010). Verhagen *et al.* (2014) argued that virtual customer service agents contribute to improve the quality of online service encounters, combining elements of both 'high tech' and 'high touch' and overcoming the detached and computer-mediated characteristics of internet.

Virtual customer-service agents are software systems that can be used in online settings to act as recommendation agents. They can combine multiple graphic options with high levels of interactivity encouraging two-way conversation and offering recommendations in an intuitive manner, thus enriching traditional websites' functions (Alves & Soares, 2014). These virtual customer service agents, act as recommendation agent and can take the form of human-like avatars offering a sort of social presence that can create feeling of warmth, and the perception that there is a personal, sociable and sensitive human contact (Etemad-Sajadi & Ghachem, 2015).

Earlier approaches to understand technology use have focused on utilitarian factors, in particular the Technology Adoption Model (TAM) which posits that perceived usefulness and perceived ease of use are the two beliefs relevant for determining attitudes toward technologies (Davis, 1989). However, hedonic factors have also been pointed as important not only to explain the decision to buy online but also to improve the quality and emotional pleasure of the user experience (Fiore *et al.*, 2005; Bilgihan, 2016). Our paper contributes to this stream of research by focusing on perceived visual attractiveness, perceived enjoyment and sociability. We set our study in a large airline's website with a virtual customer service agent represented by a human-like avatar. We posit that the aforementioned hedonic factors improve trust in the website given enhanced confidence in making good choices allowed by the presence of a virtual customer service agent which can take the functions of a seller. Previous studies establish the relevance of trust in an online firm as a set of beliefs that the other party will refrain from opportunistic behavior and will not take advantage of a specific situation. There is, however, insufficient knowledge about the factors that lead to trust development in online settings, especially because extant work shows inconsistent results (Kim & Peterson, 2017).

Moreover, online shopping-behavior studies aimed at understanding the consumer's adoption behaviors have focused either on different outcomes, such as loyalty (Forgas *et al.*, 2012), purchase/patronage intention (Van Der Heijden *et al.,* 2003; Kim *et al.,* 2008; Wang & Fodness, 2010; Dabholkar & Sheng,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2012; Alves & Soares, 2014) or purchase (Kim *et al.*, 2008). However, studies focusing on loyalty are scarce. Loyalty is obviously an important outcome as, ultimately, the success of a business can be measured by the number of returning customers. In online transactions, loyalty, also referred to as e-loyalty, has been defined as the intention to visit and make purchases in the future (Forgas *et al.,* 2012). In parallel, it is also important to assess the satisfaction experienced with the decision to visit and shop online. Despite the fact that satisfaction and loyalty have an asymmetric relationship (Oliver, 1999), a satisfied customer is more likely to return (Pappas *et al.*, 2014). Thus, this paper probes on these two outcomes: satisfaction and loyalty.

Hence, this study focuses on the impact perceived visual attractiveness, perceived enjoyment and sociability of trust, satisfaction and subsequently, loyalty. This is particularly relevant in the sense that we know little about the role of the hedonic factors as antecedents of trust and satisfaction and their effect on e-loyalty in websites displaying a virtual customer service agents.

The remainder of this chapter is organized as follows: first, we present the conceptual background on the impact of hedonic factors in using online interfaces, leading to the proposed model and hypotheses. Then, the methodology and empirical study are discussed. The final section addresses the conclusion, limitations as well as makes suggestions for future research.

LITERATURE REVIEW AND HYPOTHESIS

Hedonic Factors in Online Use

Earlier approaches to understand technology adoption have focused mainly on utilitarian factors. However, hedonic dimensions have also been pointed as relevant not only to explaining the decision to buy online but also to improving the enjoyment of the consumption experience (Bilgihan, 2016). Before the advent of online shopping, Hirschman and Holbrook (1982) had long discussed how consumption experiences can offer satisfaction or enjoyment, independently of the instrumental (utilitarian) value (see also, Holbrook & Hirschman, 1982). This is linked to the hedonic value provided by these experiences translated in their potential to arouse fantasy, as well as emotions and entertainment (Holbrook & Hirschman, 1982). Positive interpersonal engagement offered by retail shopping can render delight to such experiences (Elmashhara & Soares, 2019). However, establishing a social connection with a potential buyer is far more difficult in the virtual context rather than in the real world (Etemad-Sajadi & Ghachem, 2015). Yet, in line with several authors, when potential buyers experience an inspiring, involving and fun-creative online experience, they are more likely to be involved (Kohler *et al.*, 2011). Social cues intrinsic in avatars taking the role of virtual customer service agents induce perceptions of website socialness, leading to increased pleasure and arousal (Wang & Fodness, 2007; Etemad-Sajadi & Ghachem, 2015).

Trust

The body of literature on trust is extensive, since it has been object of study of multiple disciplines given its centrality for interpersonal and intergroup behavior and its eclectic nature (Van Der Heijden *et al.*, 2003; Corritore *et al.*, 2003; Kim *et al.*, 2008). Exchange theories and relationship marketing posit that trust is a key condition for dyadic relationships (Schurr & Ozanne, 1985; Moorman *et al.*,1993). In short,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

trust refers to the confidence that one's partner is reliable and has integrity (Rotter, 1967; Moorman *et al.*, 1993). Trust has been defined as "the belief that a party's word or promise is reliable and a party will fulfill his/her obligations in an exchange relationship" (Schurr & Ozanne, 1985, p. 940). However, research in trust in online contexts produced inconsistent results (Kim & Peterson, 2017).

In online contexts, the role of trust is a prerequisite for exchanges as in other transaction contexts (Corritore *et al.*, 2003; Kim *et al.*, 2008; Pengnate & Sarathy, 2017), and has been studied often in the ecommerce literature (Kim & Peterson, 2017). Trust is essentially a belief that "the selling party or entity will fulfil its transactional obligations as the consumers understands them" (Kim *et al*., 2008, p. 545). Trust, thus, refers to the willingness to depend on the goodwill of the trader and act in accordance with the recommendations of the seller and/or website (McKnight *et al.*, 2002).

Studies on online trust have initially looked at technical aspects, such as privacy and security and perceived web quality (Kim *et al.*, 2008; Al-Debei *et al.*, 2015). For example, a substantial body of research focuses on the connections between trust and perceived risk (Jarvenpaa *et al.*, 2000; Van Der Heijden *et al.*, 2003; Chang & Chen, 2008). However, studies focusing on other behavioral determinants of trust in ecommerce and online settings are scarcer. Bart *et al.* (2005) looked at website and consumer characteristics antecedents of online trust. Website characteristics included factors such as navigation and presentation features while consumer characteristics, included factors such as familiarity, expertise with the website and online entertainment. Kim *et al.* (2008) have developed a model of the antecedents of trust and proposed the following typology of antecedents: Cognition (observation)-based: e.g., protection issues; Affect-based, such as reputation or word-of-mouth; Experience-based: e.g., familiarity, previous experience, etc. and Personality-oriented. Wang and Fodness (2010) argue that the emotional element of experience is important online and that virtual customer service agents can contribute to mimic the interaction with a salesperson thus eliciting positive emotions.

Below, we discuss the perceived visual attractiveness, perceived enjoyment, and sociability, as relevant dimensions for online use. We posit that these factors are relevant because they have an impact on trust followed by satisfaction with the online experience which, in turn, impacts on loyalty.

Perceived Visual Attractiveness

Perceived visual attractiveness refers to ''the degree to which a person believes that the website is aesthetically pleasing to the eye''(Van der Heijden, 2003, p. 544). Robins and Holmes (2008) found that page aesthetics affected users' decision to remain or leave the website. Other studies have shown that the interface visual aesthetics contributes to not only to users' satisfaction (Lavie & Tractinsky, 2004; Tractinsky *et al*., 2004) but also to online trust (Pengnate & Sarathy, 2017).

A meta-analysis of online trust relationships in e-commerce showed that design quality, referring to the "the perception of the balance, emotional appeal, aesthetics, and uniformity of the website's overall visual look" (Kim & Peterson 2017, p. 46) impacts online trust. This impact is due to the fact that a visually appealing website indicates the vendor's ability and professionalism, which tends to generate trust (Bart et al. 2005; Kim & Peterson 2017). Thus, the following hypothesis is proposed:

H1. The higher the perceived visual attractiveness, the greater online trust.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perceived Enjoyment

The Perceived Enjoyment dimension, that is, the perception that using the computer was "enjoyable in its own right, apart from any performance consequences that may be anticipated'' (Davis, Bagozzi, & Warshaw, 1992, p. 1113) was also pointed as an important factor. This factor was shown to impact positively both on the attitude towards use and the intention to use (Dickinger *et al.*, 2008; Teo & Noyes, 2011; Van der Heijden, 2003).

Hedonic consumption experiences are by definition enjoyable or pleasurable. Enjoyment of technology has been found to be related to online initial trust in e-commerce (Chen & Barnes, 2007), and, in general, a positive experience online can lead to trust in the company (Koufaris & Hampton-Sosa, 2002; see also Bilgihan, 2016). Indeed, enjoyment creates positive associations in one's minds that should nurture trust.

H2. The higher the perceived enjoyment, the greater online trust.

Sociability

With regard to the sociability dimension, it refers to the perception of social presence and sensitive human contact through the medium (Wang & Fodness, 2010). This perception of social stimuli as courtesy, kindness, empathy and sympathy has been deemed important to overcome the consequences of the lack of face-to-face interactions between the consumer and the seller in online settings (Alves & Soares, 2014). Verhagen *et al.* (2014) argued that virtual customer service agents contribute to improve the quality of online service encounters, combining elements of both 'high tech' and 'high touch' to form a new type of service encounter: the 'social online service encounter'. In the same line, a study by Wang and Fodness (2010) revealed that consumers' perceptions of sociability, emotional answers, and trust toward the online seller are more positive when the online store contains an avatar with the capacity to be likeable and to empathize with the consumer.

Using a virtual customer service agent has also been identified as an important factor to offer consumers a more personalized experience (Alves & Soares, 2014; Moon *et al.*, 2013). In particular, extant research has posited that avatar-like virtual customer service agents can contribute to mitigate one of the main limitations of ecommerce: the lack of personalization and possibility of interaction with a sales person. Avatars offer a degree of humanness and socialization, allowing consumers to engage in conversations with sellers. This interaction and dialogue contributes to reduce ambiguity, reduce risk and increase trust. Hence, some studies found social presence to positively impact trust (Gefen & Straub, 2003). Thus, we propose:

H3. The higher the sociability, the greater the online trust.

Satisfaction

Consumer satisfaction has been defined as pleasurable fulfilment (Oliver, 1999), referring to the consumer perception that the purchase/consumption positively fulfils some needs, desires or goals. Satisfaction is key for customer retention and loyalty (Pappas *et al.*, 2014). In fact, a satisfied customer is more likely to return (Lee *et al.*, 2009), making satisfaction not only a key factor that affects customers' online purchase behaviour but also an important factor of customer loyalty. In their seminal study, Szymanski and Hise

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(2000) developed and tested a model of the determinants of e-satisfaction, and found that convenience, site design, and financial security were the most relevant factors for e-satisfaction (see also, Lin & Sun, 2009).

Several studies have proposed a link between trust and satisfaction (Kim *et al.*, 2008; Wu, 2013; Pappas *et al.*, 2014; Kim & Peterson, 2017). For example, Pappas et al. (2014) found that trust impacts positively satisfaction, regardless the level of consumer experience with online shopping. A meta-analysis study of antecedents of outcome of online trust in e-commerce found that out of six consequences of trust studied, satisfaction was the most strongly related (Kim & Peterson, 2017). Hence:

H4. The higher the trust, the higher the satisfaction.

Loyalty

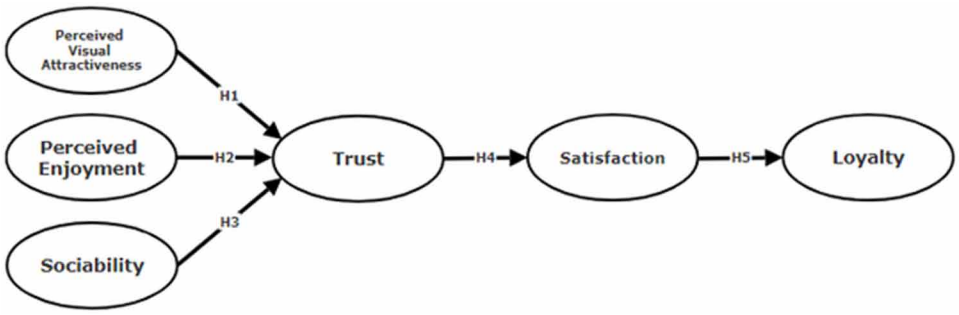
Gaining the loyalty of customers is arguably the ultimate goal of businesses. Loyalty has been defined as "a deeply held commitment to re-buy or re-patronize a preferred product/service consistently in the future, thereby causing repetitive same brand or same brand-set purchasing, despite situational influences and marketing efforts having the potential to cause switching behavior" (Oliver, 1999, p. 34).

Previous research has shown that satisfaction has a positive relationship with online shopping tendency (Zhou *et al.,* 2007). The link between trust and loyalty has been investigates by several studies, including in the online context (Forgas *et al.,* 2012; Yüksel *et al.*, 2007; Lin & Sun, 2009). Thus, the following is proposed:

H5. The higher satisfaction, the higher loyalty.

Figure 1, below, displays the research model and the proposed hypotheses.

Figure 1. Research model



METHODOLOGY

The purpose of this study is to assess the antecedents of satisfaction and their implications after the introduction of an avatar in the website of a large airline company. This website is used for making reservations and buying flights. We will henceforth refer to this site as unidentifiedairline.com (for

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

anonymity reasons). With such purpose in mind, we used a quantitative methodological approach as it seems to fit our research objectives. Our sample comprises 132 website users.

Profile of the Sample

The demographic profile of the respondents is presented in Table 1. The vast majority of respondents are male and middle-aged. Equally, most of them have a degree (86.4%) and around 60% belong to top management. Because we wanted to understand hedonic online experiences amongst those that are not new to the process, all of our participants are frequent flyers.

Data revealed that on a scale of 1 (disagree totally) to 7 (agree totally) the sample of respondents recommend the site unidentifiedairline.com (M=5.5; SD=1.2), if the respondents need to travel, they do not hesitate to book their travel through unidentifiedairline.com (M=5.6; SD=1.4). Also, they think the unidentifiedairline.com is a good site (M=5.10; SD=1.35) and in general they are very satisfied with unidentifiedairline.com (M=5.15; SD=1.20).

Table 1. Respondent profile

Variable		Frequency	% valid (Total)
Gender	Female	34	25.8%
	Male	98	74.2%
Age	73-55	61	46.6%
	54-39	61	46.6%
	38-24	8	6.1%
	>23	1	0.8%
Level of Education	Primary school	2	1.5%
	Secondary school	16	12.1%
	Higher education	114	86.4%
Occupation	Top Management	80	60.6%
	Middle Management	17	12.9%
	Qualified Workers	35	26.5%
Frequency of use the site unidentifiedairline.com	Sporadically	80	60.6%
	One time per week	30	22.7%
	More than one time per week	22	16.7%

Measurement Scales

Validated scales for the constructs of interest were sourced from the literature (van der Heijden, 2003 & 2004; Wang & Fodness, 2010; Alves & Soares, 2013; Forgas *et al.*, 2012).

In what concerns *perceived visual attractiveness* the items that tap into the construct are: "Overall, I find that unidentifiedairline.com looks attractive"; "The layout of unidentifiedairline.com is attractive" and "The colors, images and dynamic elements that are used on unidentifiedairline.com are attractive".

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

All these items were measured using a seven-point Likert scale. For *sociability*, we used six items adapted from Wang and Fodness (2010) and Alves and Soares (2013). Specifically, respondents were asked to rate the company website for each of the following attributes: Friendly; Warm; Helpful; Polite; Informative and Intelligent. A seven-point rating scale (1 = describes poorly/ 7 = describes perfectly) was used to measure these items. Regarding *perceived enjoyment*, we resorted to prior work from van der Heijden (2003). Four seven-point semantic differential scaled items were used to classify the website navigation, specifically: Enjoyable/disgusting; Pleasant/unpleasant; Exciting/dull and Interesting/boring.

With regard to *Trust*, we used four items which were adapted from Bart, Shankar, Sultan and Urban (2005) and Alves and Soares (2014) and include the following items: "The unidentifiedairline.com website appears to be more trustworthy than other similar websites I have visited"; "The unidentifiedairline.com website represents a company or organization that will deliver on promises made"; "The information set out in the unidentifiedairline.com website deserves my trust"; "I trust the recommendations of the unidentifiedairline.com website". For *Satisfaction,*_we used three items adapted from Forgas et al. (2012). Specifically, respondents were asked to classify the company website for each of the following items: "The website meet my expectations"; "All the contacts with the unidentifiedairline.com website are satisfactory" and "In general, I am satisfied with the unidentifiedairline.com website".

Finally, the items that tap into *Loyalty* were adapted from Forgas et al. (2012). Specifically, the following items measured on a seven-point Likert scale were used: "I like the unidentifiedairline.com website"; "I think unidentifiedairline.com is a good website"; "If I need it, I shall continue to book a flight on the unidentifiedairline.com website" and "I shall continue to recommend unidentifiedairline.com website".

DATA ANALYSIS

In order to test our research hypotheses, we used the PLS with SmartPLS v.3.2 (Ringle, Wende, & Becker, 2015), which is a SEM tool that focuses on the prediction of dependent variables, is not so demanding with regard to multivariate normal data and uses both formative and reflective constructs (Fornell & Larcker, 1981).

Before testing the research hypotheses an assessment of the constructs' psychometric properties (convergent validity, reliability and discriminant validity) was performed. Furthermore, despite the measurement and structural parameters are estimated together, the PLS algorithm is computed in two stages: 1) the assessment of the measurement model and 2) the assessment of the structural model. This sequence ensures that the constructs' measures are valid and reliable before attempting to draw conclusions regarding the major relationships among constructs (Barclay *et al.,* 1995).

Assessment of the Measurement Model

In line with Mackenzie *et al.* (2005) recommendations, only the sociability construct was conceptualized as formative whereas the remaining constructs were considered as reflective. When examining the formative model, it is crucial to evaluate both the potential multicollinearity between items and the analysis of their weights (Róldan & Sanchez-Franco, 2012). High Collinearity between items cause unstable estimates and make difficult to isolate the distinct effect of an individual item on its intended construct. Frequently, the maximum variance inflation factor (VIF) value for each variable indicates

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the presence of multicollinearity, i.e., a VIF above 3.3 indicates a multicollinearity problem (Róldan & Sanchez-Franco, 2012). At the present study all items are below the VIF cut-off point (Table 2).

The next step requires the assessment of weights, which measures the contribution of each items to the variance of the construct. A significant level of at least 0.05 suggests that a formative indicator is relevant for building a composite construct (Róldan & Sanchez-Franco, 2012). In order to test the significance of weights a bootstrapping resampling procedure of 5000 resamples was computed. Along this process only two of six formative items measuring sociability were identified as having a t-value below 1.96. Yet, in line with several authors, we decided to keep these items because deleting an item would imply to remove a part of the composite construct (Roberts & Tatcher, 2009).

The measurement model for reflective constructs is assessed in terms of individual item reliability, construct reliability, convergent validity and discriminant validity. In other words, we have examined the Composite Reliability (ρc), Cronbach's Alpha and rho_A, all of which present values above 0.70 (Henseler *et al.,* 2016). Convergent validity is evidenced by the large and significant standardized loadings ($t > 1.96$) and the average variance extracted (AVE), which ranged from 0.65 to 0.87. This indicates that the items are above the recommended cut-off point and share (on average) at least half of their variance with the construct (Bagozzi & Yi, 1988; Chin, 1998). Table 2 indicates that all reflective latent constructs satisfy this condition.

Table 2. Measurement scales (Factor Loadings, Weights and Reliabilities)

Items for each construct (Reflective Constructs)	Factor Loading	t-value
Trust (CR=0.88;CA= 0.82; Rho=0.84; AVE= 0.65)		
The website appears to be more trustworthy than other similar websites.	0.72	13.4
The website represents a company that will deliver on promises made.	0.76	12.9
The information set out in the website deserves my trust.	0.89	40.0
I trust the recommendations of the unidentifiedairline.com website.	0.85	26.8
Satisfaction (CR=0.95;CA= 0.92; Rho=0.93; AVE= 0.87)		
The website meets my expectations	0.94	89.5
All the contacts with the unidentifiedairline.com website are satisfactory.	0.89	26.7
In general, I am satisfied with the unidentifiedairline.com website	0.95	127
Perceived Attractiveness (CR=0.94;CA= 0.91; Rho=0.91; AVE= 0.85)		
Overall, I find that unidentifiedairline.com looks attractive.	0.92	30.0
The layout of unidentifiedairline.com is attractive.	0.94	46.2
The colors, images and dynamic elements on the website are attractive	0.91	44.0
Perceived Enjoyment (PE) (CR=0.94;CA=0.91; Rho=0.92; AVE= 0.80)		
Enjoyable / Disgusting (1)	0.90	45.5
Pleasant / Unpleasant (2)	0.91	45.9
Exciting / dull (3) Interesting / boring (4)	0.84 0.92	25.7 49.6
Loyalty- affective + conative (CR=0.95;CA=0.93; Rho=0.95; AVE= 0.83)		
I like the unidentifiedairline.com website	0.95	146
I think unidentifiedairline.com is a good website	0.94	115

Table 2. Continued

Items for each construct (Reflective Constructs)		Factor Loading	t-value
If I need it, I shall continue to book a flight from the airline website.		0.80	15.2
I shall continue to recommend unidentifiedairline.com website		0.95	89.7
Formative Construct - Sociability	**VIF**	**Weight**	**t-value**
1.Friendly	2.78	0.10	0.70
2.Warm	2.98	0.08	0.60
3.Helpful	3.28	0.59	3.51
4.Polite	2.24	0.07	0.50
5.Informative	2.47	0.45	2.44
6.Intelligent	3.32	0.04	0.50

This study follows two approaches to assess discriminant validity, which indicates the extent to which a given construct differs from other constructs. First, the Fornell-Larcker criterion was used, thereby we compare the square root of the AVE for each construct with the correlations between the focal construct and other constructs. For adequate discriminant validity, the diagonal elements should be significantly greater than the off-diagonal elements in the corresponding rows and columns (Roldán & Sánchez-Franco, 2012). Relying on this criterion, the data suggests acceptable discriminant validity (Fornell & Larcker, 1981). Second, we adopted the heterotrait-monotrait ratio (HTMT) as another criteria. Here we compared the obtained values with a predefined threshold (Henseler *et al.,* 2015). Table 3 shows that only one HTMT value equals the 0.85 threshold, so there are reasons to believe that there is no problem associated with discriminant validity.

Based on previous analyses, we concluded that the proposed measurement scales shows unidimensionality and conceptual consistency.

Table 3. Pearson Correlations, Means and Standard Deviations

Fornell-Larcker	1	2	3	4	5	6	HTMT	1	2	3	4
Loyalty	(0.91)						(1)				
Perceived Attractiveness	0.77	(0.92)					(2)	0.82			
Perceived Enjoyment	0.79	0.73	(0.89)				(3)	0.84	0.79		
Satisfaction	0.88	0.71	0.76	(0.93)			(4)	0.85	0.77	0.81	
Sociability	0.79	0.67	0.76	0.72	(-)		(5)	0.79	0.77	0.76	0.74
Trust	0.71	0.67	0.67	0.66	0.71	(0.81)	(6)				
Mean	5.27	4.94	5.00	4.93	5.04	5.20					
Standard Deviation	1.30	1.12	1.09	1.29	1.11	1.04					

Notes: The diagonal (in brackets) shows the square roots of the AVE;

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Assessment of the Structural Model

Based on a satisfactory assessment of the measurement model, the proposed hypotheses of the conceptual model can be estimated throughout the statistical significance of path coefficients. In order to generate the path coefficients, t-statistics and standard errors, the bootstrap procedure (5,000 resamples) was used. This technique generates a large number of sub-samples from the original sample through the systematic deletion of observations. The t-values and 95 percent bootstrap confidence intervals were computed to provide additional information on the stability of the coefficient estimates. As Castro and Roldán (2013) observed, the percentile approach is recommended because it has the advantage of being completely distribution free. Results are depicted in Table 4.

Table 4. Results of Hypothesis Testing

Paths Coefficients	Direct Effects	t-Value (bootstrap)	Conf. Interval	Supported
H1: Perceived Visual Attractiveness → Trust	0.29***	3.61	[0.179-0.443]	Yes
H2: Perceived Enjoyment → Trust	0.16*	1.90	[0.003-0.312]	Yes
H3: Sociability → Trust	0.39***	4.35	[0.178-0.504]	Yes
H4: Trust → Satisfaction	0.66***	10.95	[0.542-0.748]	Yes
H5: Satisfaction → Loyalty	0.88***	28.1	[0.812-0.922]	Yes
Controls				
Age → Loyalty	-0.07	1.62	[-0.140-0.001]	-
Education → Loyalty	-0.03	0.72	[-0.110-0.330]	-
Gender → Loyalty	0.04	0.99	[-0.025-0.116]	-

Based on t (4999); *p<0.05; t (0.05; 4999) = 1.645; ***p<0.001; t(0.001;4999) = 3.092; †bias-corrected and accelerated (BCa) BCI; one-tailed.

The predictive power of the model was also examined by assessing the cross-validated communality, the cross-validated redundancy index (Q2) and the coefficient of determination (R2) (Table 5). As acknowledged by Chin (1998), goodness-of-fit in a PLS estimation is demonstrated by strong factor loadings, significant path coefficients, high R2 values and Q2 values above zero. For instance, the proportions of the total variance in each endogenous construct explained by the model are: 78% for loyalty, 58% for trust and 43% for satisfaction. These values are largely above the minimum of 10% set for R2 of the endogenous variables. After analyzing the results it was concluded that the model showed predictive relevance.

Table 4 shows that all proposed hypotheses are positively and statistically significant. It is relevant to emphasize that the larger impact relates to the Hypothesis 5 that maintains that the higher the Satisfaction, the greater the loyalty (β=0.88; $p<0.001$). This is followed by the impact of Trust on Satisfaction (β=0.66; $p<0.001$) confirming H4.

The third larger impact relates to H3, which refers to the impact of Sociability on Trust (β=0.39; $p<0.001$).This is followed by H1 (β=0.29; $p<0.001$), which predicts that Perceived Visual Attractiveness (PVA) has a positive impact on Trust. Finally, it was also confirmed that Perceived Enjoyment has a positive and significant impact on Trust (β=0.16; $p<0.05$), confirming H2.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Effect size of the endogenous variables

Latent Variables	R^2	CV-C Q^2	CV-R Q^2
Loyalty	0.78	0.70	0.60
Perceived Visual Attractiveness	-	0.61	-
Perceived Enjoyment	-	0.61	-
Satisfaction	0.43	0.64	0.35
Sociability	-	0.45	-
Trust	0.58	0.41	0.34

CV-C (Cross-validated communality); CV-R (Cross-validated redundancy).

This study also applies several control variables, such as age, education and gender, however, results show that these do not affect significantly loyalty.

CONCLUSION

This study investigated the effect of hedonic factors in the navigation experience in satisfaction, trust and website loyalty. The primary theoretical contribution of this study lies in investigating the joint effects of hedonic and emotional functions embedded in a website featuring a virtual customer service agent of a large airline. This study focused on three major factors, namely, perceived visual attractiveness, sociability and perceived enjoyment. Taken as a whole, the results of our study confirm that these hedonic dimensions affect positively trust, which in turn affects satisfaction. Thus, pleasant online shopping environments seem to predispose consumers to trust more the e-seller, which impacts positively on the overall satisfaction with the online experience. This later subsequently impacts significantly and positively on loyalty. This is important since creating hedonic experiences online can be complex, where there is no real physical setting or store atmosphere to persuade consumers, as well as no one to physically interact with consumers. As this study suggests, virtual customer service agents, and other forms of immersive environments can facilitate such engagement with positive effects on the whole customer experience.

In particular, our study suggests that improving the aesthetics of the website improves the quality of the navigation and the quality of the consumer experience online, specifically by improving the trust on the site and this leads to satisfaction with the website. This corroborates Pengnate and Sarathy's (2017) findings that visual appeal helps to create a positive user experience and develop online trust. This, in turn, leads to higher loyalty.

Finally, certain shortcomings of the study need to be kept in mind. First, these results are not generalizable, though we believe this study may be a relevant contribution to the understanding of online behavior of consumers of airline companies. Second, this study did not focus on the utilitarian dimension of the consumer's online experience as our main goal was to understand the hedonic dimension and the former may affect the latter. Given the rapid advances of the graphical user interface technologies, it would be expected that in a near future the tasks assigned to this functionality will be more complex and interactive. Understanding how these developments affect consumer encounters online, for different types of tasks with varying levels of complexity, will remain a fertile area for further research.

KEY TERMS AND DEFINITIONS

Avatars: Similar to virtual customer service agents. Computer-generated characters with whom consumers can interact with when navigating an online platforms.

Perceived Enjoyment: Refers to the perception that using the website is enjoyable, pleasant and interesting.

Perceived Visual Attractiveness: Refers to the perception that the website is aesthetically pleasing.

Recommendation Agents: Similar to virtual customer service agents; Electronic screening tools that act as decision and recommendation aids to customize online shopping experiences.

Satisfaction: The perception by the consumer that the purchase/consumption positively fulfils some needs, desires or goals.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sociability: Refers to the perception of personal, sociable, and sensitive human contact in the website navigation.

Trust (Online Trust): The confidence that the website is reliable, has integrity and will fulfil his/her part.

Virtual Customer Service Agents: Computer-generated characters with whom consumers can interact with when navigating an online platforms.

Chapter 41
Determinates of Live Support Chat in Organizational Intranets: An Empirical Study in Kuwait

Ahmed Elmorshidy
https://orcid.org/0000-0002-2078-555X
Gulf University for Science and Technology, Mubarak Al-Abdullah, Kuwait

ABSTRACT

Live support chat (LSC) is a relatively new type of online customer support that is growing significantly in e-commerce websites. LSC bypasses the traditional types of customer support like phone, e-mail and web forms and it provides instant answers to customers' questions and concerns. Few researchers have empirically examined the factors affecting LSC at the individual level, however there is no evidence of research that explored the determinates of LSC in an organizational context and how it affects employees. This study attempts to fill this research gap by empirically examining the factors that affect LSC in the context of the organizational Intranets. Survey data from 389 employees at private and public organizations in Kuwait were collected to test the study hypotheses. The study findings have important implications at both the theoretical and practice levels.

INTRODUCTION

Live Support Chat (LSC) is a relatively new type of online customer support that is growing significantly in E-commerce websites. LSC bypasses the traditional types of customer support like phone, e-mail and web forms and it provides instant answers to customers' questions and concerns. We now live an era where online customers and employees are more demanding and require that their problems, questions and concerns be answered on the spot rather than even to wait for just a few hours to get a response. Few researchers have empirically examined the factors affecting LSC at the individual level (Ilk et al., 2012; Elmorshidy, 2013; Elmorshidy et al., 2015). There is also a limited number of research paper that

explored the determinates of LSC in an organizational context and how it affects employees as demonstrated in section 2.2 of the paper. This study attempts to fill this research gap by empirically examining the factors that affect LSC in the context of the organizational Intranets.

Online chat may refer to any kind of communication over the Internet which offers an instantaneous transmission of text-based messages from sender to receiver; hence the delay for visual access to the sent message shall not hamper the flow of communications in any of the directions. (Andrews, 2010). Now not just text-based information can be communicated through LSC but also images, sound and videos. Although early attempts to implement LSC existed a few years ago in a limited number of websites, the wide spread and actual use of this technology has grown exceptionally in the past four years to reflect a new paradigm shift in online customer support in e-commerce websites. LSC just recently became a new standard of service that online customers demand and expect while shopping or doing business online. (Elmorshidy et al., 2015).

LSC is viewed as a cost-effective way to reduce purchasing risk through increasing social interaction. It has also been regarded as a good method to respond to consumers' questions, and to personalize the shopping experience. There is also evidence demonstrating that this customer service solution improves the online shopping experience itself and reduces purchase abandonment rates. (Elmorshidy et al., 2015).

In an observation by Shane at al. (2007), service agents could handle at least three chat sessions simultaneously without significant increase in average chat duration. Other studies indicated that commercial live chat systems allow service agents to multi-task ten or more chat sessions. This feature is promoted by LSC vendors as a unique strength of live chat systems to maximize service productivity (Ilk et al., 2012).

This paper starts by reviewing literature that leads to the development of the research hypotheses pertaining to the determinates of LSC in the context of the organizational Intranets. The paper then discusses the research methodology including the research model and sampling. The research results and finding are then provided and analyzed. The conclusion section at the end of the paper discusses theoretical contributions, implication for practice and the limitation of the study as well as recommendations for future research.

LITERATURE REVIEW AND HYPOTHESES DEVELOPMENT

Live Support Chat in an Organizational Context

Glass and Li (2010) mentioned that one of the most appealing attributes of Instant Messaging (IM) as a live chat tool for businesses is the fact that unlike the delayed, asynchronous nature of e-mail, the current online status or presence of the intended recipients is displayed and allows for immediate response." They added that Approximately 45 to 50 percent of US firms currently permit their employees to use IM for business purposes and IM will be the de facto tool for voice, video and text chat with 95% of workers in leading global organizations. Glass and Li (2010) empirically investigated factors that influence individuals to adopt IM in the workplace. Findings showed that subjective norm, perceived critical mass, perceived usefulness and perceived ease of use were factor in determining IM adoption than the organization.

Ou et al. (2010) mentioned that Instant messaging (IM) technology as a live chat tool is currently growing rapidly in a variety of contexts. An IM has the capability to connect individuals instantly, thus

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

enabling almost real time interaction in a cost-effective manner, unlike other communication tools such as e-mail, video conferencing and online communities. Although IM is widely used in social contexts, its adoption in the work place remains controversial. Ou et al (2010) added that live chat tools have a potential to empower teamwork by establishing social networks and facilitating knowledge sharing among organizational members. Organizations are increasingly allocating complex tasks to teams, which consequently require more efficient communication and knowledge sharing for problem solving. Benefitting from IMs characteristic of instantaneous connections, the collaborative process among team members can be much smoother. Instant communication provides organizations with the opportunity to become real-time enterprises.

Robb (2001) mentioned that IM as live chat tool is emerging as a potent weapon in the corporate communications arsenal, led primarily by leading lights in the financial sector. Ernst & Young, UBS Warburg, State Street Bank, Thomas Weisel Partners and PaineWebber, which have all implemented some kind of IM or live chat system. Though some of these are purely internally facing, IM is also evolving into an external tool to enhance interaction with financial planners. Todd Bertsch, CEO of A.W. Bench in New York City, for example, says that instant messaging via wireless handhelds has made his brokers far more productive and also lets financial planners focus on critical information (Robb, 2001).

Zhang and Fjermestad (2008) employed a comparative case study approach about how instant messaging (IM) as a live chat tool can be in various ways in small businesses for organizational benefits. They mentioned that in the global economy, benefits of IM low-cost yet productive communication technologies to communicate with dispersed partners was innovative. Their results showed that small business managers play an important role in creating a constructive and creative communication strategy to achieve several benefits such as productive enhancement, knowledge sharing, relationship building and customer support.

Ou et al. (2010) developed a research model that explains how instant messaging (IM) as a live chat tool technology enable employees to be empowered. The paper uses survey of 253 Chinese work professionals with respect to their use of IM tools at work. Results showed that IM does empower work teams via shaping the social networks and facilitating knowledge sharing in the workplace, resulting in heightened team performance.

Chieh-Peng and Chou-Kang (2011) mentioned that helping intention is an important value that holds the key to the continuous user growth of instant messaging (IM) as a live support tool. They conducted a study to validate a research model that examines online helping intention from a perspective of online social capital. Empirical testing of this model, through a survey of employees from seven large companies, confirms some theoretical expectations of this study. Two of the seven companies are from general service industries and the other five companies are from high-tech industries. Of the 500 questionnaires distributed to participants, 364 usable questionnaires were returned for an effective response rate of 72.8%. Helping intention is influenced by reciprocity, shared narratives, centrality, and network ties, whereas commitment and shared codes and language are not significantly related to helping intention.

Licoppe (2010) conducted two empirical case studies on the uses of mobile musical ringtone and of instant messaging in organizations, showing the kind of work that users actually do to pattern their environments with an orientation toward shaping in advance the way in which they might be interrupted and notified. Concerned with how they might be notified, the users are becoming more skilled and turning into "pragmatic amateurs," less inclined to accept the imposition of a summons (which also testifies to a kind of "crisis of the summons"), and with a keener sense for appreciating the working and pragmatic consequences of a given type of notification.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Zhang and Fjermestad (2008) explained that independent low-cost instant messaging (IM) as live chat tools may allow small businesses with limited financial and technical resources to communicate and collaborate internally and externally. They added that little research has been done investigating IM in the small business context. Their study investigated how small businesses respond to and actively exploit the opportunities brought by IM. Two comparative case studies were conducted with two US small businesses. Multiple data collecting methods were used including observation, interview, and IM transcripts. Results showed that IM was found beneficial to small businesses in several way and that creative and constructive usage of IM could bring a variety of organizational benefits to small businesses. The study also showed that IM usage management is more a managerial issue than a technical one and a set of organizational and managerial factors were identified critical to the achievements of these benefits.

Ajjan et al. (2014) stated that Instant messaging has been widely utilized as a live chat tool by a variety of types of organizations to improve the efficiency and effectiveness of internal communication and knowledge management (KM). To date, though, the continuance use of enterprise instant messaging (EIM) and its impact on KM outcomes have not been well understood in both academia and practice. Ajjan et al. (2014) used the theory of planned behavior to explore factors that influence continual usage of EIM applications within organizations, as well as the impact of the continuance use decisions on knowledge creation, transfer, and retention within organizations. Results were useful in developing guidelines and strategies to increase the likelihood of the continuance use of EIM and to improve the potential outcome of its use within organizations.

Shen et al. (2012) investigated the adoption and use of instant messaging as a group-referent intentional social action. The concept of 'we-intention', which refers to one's perception of the group acting as a unit was the focus of interest. The cognitive, affective and social dimensions that contribute to 'we-intention' to adopt and use instant messaging were investigated. A survey was conducted, and the findings provided empirical evidence supporting the idea that cognitive, affective and social factors jointly lead to the development of we-intention. With the prevalence of instant messaging in organizations, managers are able to harness the collective wisdom of employees and find out the most effective solution to their problems. Managers also should make good use of the special features of instant messaging, such as messaging conferencing, chat room and white boarding, to promote employees' identification with the collaborative group and to enhance the similarity among group members.

Pazos et al. (2013) mentioned that fast-paced organizational environments and growing needs for permanent and fast connectivity have steered the adoption of technologies such as instant messaging (IM) for organizational communication. However, the use of IM as a communication tool to support task completion is not well understood. They conducted an exploratory mixed methods study investigating the use of IM as a communication tool to support task completion and multitasking in information technology organizations. The main purpose was to investigate IM use to support two types of tasks: collaboration and conflict tasks. They used a mixed methods approach incorporating quantitative and qualitative data from interviews and survey instruments. Results from the quantitative analysis suggest a significantly greater use of IM for collaboration tasks than for cognitive conflict tasks. The qualitative data helped in identifying specific tasks in the information technology corporate environment whose completion is supported by IM use. Those tasks were mapped into an existing task framework and analyzed using qualitative methods. Results from the qualitative analysis were used to complement and support the quantitative findings.

Licoppe (2014) studied the work and communication practices of two highly connected organizations, the members of which have all access to instant messaging (IM) as live chat support tools on a profes-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

sional basis. They documented the development of a communicational genre, that of 'quick questions', and analyze the sequence organization of such IM conversation threads. Results showed that 'quick questions' enable the collaborative accomplishment of complex, knowledge-intensive tasks by recruiting colleagues constituted as experts capable of quickly answering information requests related to ongoing tasks. 'Quick questions' articulate communicative practices, 'strong' distribution of tasks and 'organizing' in highly connected organizations. Licoppe (2014) argued that they enact a distinctive cognitive and moral economy based on minimal forms of interaction and exchanges (which we call 'contributions'), constituting a more general phenomenon.

Peslak et al. (2010) expressed that Instant messaging (IM) as a form of communication offers unique advantages to traditional email communication centered mostly on its immediacy. Levels of IM use are significantly less than email especially in business organizations. In order to understand IM behavior and encourage its adoption, Peslak et al. (2010) explored IM behavior using the Ajzen and Fishbein (1980) model of human behavior known as Theory of Reasoned Action (TRA). Results showed that attitude toward IM and "subjective norm" are positively associated with intention to use instant messaging. Also, the TRA model can be used to predict and understand the usage of instant messaging in the target population.

Hunt (2009) investigated contemporary business communication practices regarding instant messaging as a form of live chat support. The explode the strengths, weaknesses and best management practices of instant messaging in a small multinational company in the Oil & Gas industry. The research methodology included employee interviews, employee surveys, and direct observation. The interviews provided guidance for the development of the employee surveys. Findings showed that instant messaging is a highly utilized communication method in business and has become essential to efficient business operations.

Study Constructs

Drawing on research from North America, Europe and Australasia and based on several theoretical models, there is a wealth of evidence that suggest that a wide variety of factors influence LSC usage behavior. We provide the table (Table 1) to show how we extracted each factor for our study and the justification behind its selection. Those factors are perceived usefulness, perceived ease of use, compatibility, subjective norms, trust, and attitudes.

Compatibility

Compatibility was originally one of the factors determining the diffusion of innovation rate in the diffusion of innovation paradigm. It refers to the degree to which the use of the new technology is perceived to be consistent with the potential users' existing values, previous experience and needs. (Elmorshidy at al., 2015). Ifinedo (2018) empirically investigated the factors influencing students' continuance intention to use blogs to learn in an undergraduate-level course. The results showed that perceived usefulness and perceived compatibility have positive effects on students' attitudes towards blog use. Perceived compatibility perceived self-efficacy, and perceived support for enhancing social ties with blogs have significant effects on the positive impacts of learning with such tools. Ozturk et al. (2017) examined factors affecting restaurant customers' intention to use near field communication (NFC)-based mobile payment (MP) technology. More specifically, based on the valence theory, they examined the impacts of users' negative valence (perceived risk and acceptance). It was shown that compatibility exerts the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

greatest impact the intention to use MP services. Mkhize at al. (2016) empirically evaluated Learning Management System (LMS) usage in an open distance learning Institution in South Africa. The results revealed that both relative advantage and compatibility have a significant impact on the students' attitude towards the use of the LMS. Lee et al. (2011) investigate factors affecting business employees' behavioral intentions to use the e-learning system. Survey data were collected from 552 business employees using the e-learning system in Taiwan. The results showed that the effects of the compatibility is significant on both perceived usefulness and previewed ease of use and thus employees' intention to use the e-learning system. This discussion leads to the following hypotheses:

H1: Perceived compatibility of LSC services in the organizational Intranet positively influences employees' perceived usefulness of LSC.
H2: Perceived compatibility of LSC services in the organizational Intranet positively influences employees' perceived ease of use of LSC.
H3: Perceived compatibility of LSC services in the organizational Intranet positively influences employees' intention to use these services.

Table 1. Factors of the study and where they were extracted from

Study Construct	Theoretical Model Taken From	Justification
Compatibility	Diffusion of Innovation Theory (Rogers, 1960)	Diffusion of innovations is a theory that seeks to explain how, why, and at what rate new ideas and technology spread. Compatibility is the degree to which an innovation is perceived as being consistent with values, past experience, and need of potential adapters. An idea that is not compatible with their values, norms or practices will not as rapidly as an innovation that is compatible.
Trust	Theory of Perceived Risk (TPR) (Bauer, 1960)	In TPR, according to Bauer 1960, the two primary dimensions of risk are one related to uncertainty or probability of loss notion and the other is related to consequence or importance of loss notion. Bauer 1960 argues that at any transaction, individuals are forced to deal with uncertainty. Thus, trust will definitely have a positive effect on intention to use.
Subjective Norms	Theory of Planned Behavior (TBP) (Ajzen, 1991)	TBPP is a theory that links one's beliefs and behavior. Subjective norm is an individual's perception about the particular behavior, which is influenced by the judgment of significant others. (friend, parent, teacher). Subjective norms are shown to have a significant impact on intention to use.
Perceived Usefulness	Technology Acceptance Model (TAM) (Davis, 1989)	TAM is a Well-established model that has been studies intensively about how users accept and use the technology. Perceived Usefulness is shown to have a strong impact on intention to use the technology
Perceived Ease of Use	Technology Acceptance Model (TAM) (Davis, 1989)	TAM is a Well-established model that has been studies intensively about how users accept and use the technology. Perceived Ease of use is shown to have a strong impact on intention to use the technology
Attitude	Theory of Planned Behavior (TBP) (Ajzen, 1991) and Technology Acceptance Model (Davis, 1989)	In both TBP and TAM, attitude is shown to have a significant impact on intention to use.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perceived Usefulness

Perceived usefulness is defined as the degree to which an information technology system is perceived to provide benefits in performing certain activities (Davis, 1986). Dong et al. (2017) studied the factors affecting the usage of Internet of Things (IOT) in China. Perceived usefulness was shown to have a significant impact on intention to use Internet of Things. Koo et al. (2015) investigated the determinants of perceived usefulness of smart green information technology (IT) device in reducing electricity consumption. Though there are many determinants of intention to use a technology, perceived usefulness is a key determinant of continuance intention to use smart green IT devices. Almaiah (2018) empirically studied the Acceptance and usage of a mobile information system services in University of Jordan. The results revealed that user acceptance of mobile information system services is largely affected by trust, perceived security, perceived ease of use and perceived usefulness. Elmorshidy et al. (2015) empirically examined factors affecting live chat customer support in Kuwait through the technology acceptance model. The results showed a significant positive impact of perceived usefulness and perceived ease of use on the intention to use live chat support. In an empirical study by Sarrab et al. (2016), factors driving the adoption of mobile learning tools in Omani higher education were examined through the use of the technology acceptance model framework. Results showed that perceived usefulness has a significant effect on the adoption of mobile-learning. This discussion leads to the following hypothesis:

H4: Perceived usefulness of LSC services in the organizational Intranet positively influences employees' intention to use these services.

Perceived Ease of Use

Perceived ease of use is defined according to Davis (1989) as the degree to which the prospective user expects the target system to be free of effort. Al Zubi et al. (2017) mentioned that Individuals expect that, if a new technology is easy to use, this will create a positive attitude toward it. Al Zubi et al. (2017) examined the relationship between independent variables (technology, perceived usefulness, and perceived ease of use) and intention to use internet banking (IB) among 200 Small-to-Medium Enterprises SMEs owners in Yemen. The results showed a significant impact of perceived ease of use on intention to use IB among SMEs'. Joo et al. (2014) conducted a study to add new variables, namely user interface, personal innovativeness, and satisfaction in learning, to Davis's technology acceptance model TAM and also examine whether learners are willing to adopt mobile learning. The results of the structural equation modeling revealed that user interface and perceived ease of use had significant effects on perceived usefulness and intention to use. In a study of technology adoption in government agencies, Hamner and Qazi (2009) found a statistically significant association between perceived ease of use and attitude and intention to use. Elmorshidy et al. (2015) empirically examined factors affecting live chat customer support in Kuwait through the technology acceptance model. The results showed a significant positive impact of perceived ease of use perceived on the intention to use live chat support. Chin et al. (2015) explored Malaysian Internet and Mobile Banking consumers' intention in adopting a single platform E-payment system using TAM model. The empirical results showed that convenience, design, perceived risk, perceived usefulness and perceived ease of use influence consumers' intention to use single platform E-payment system. This discussion leads to the following hypothesis:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H5: Perceived ease use of LSC services in the organizational Intranet positively influences employees' intention to use these services.

Trust

Perceived risk was defined as consumer's belief about the potential uncertain negative outcomes from the online transactions. E-commerce risk can be conceptualized as a function of data protection and system reliability. (Velmurugan, 2009). Yu et al. (2017) explored how trust can transfer among diverse business channels in smart phone industry. They further examined the impact of trust repairing strategies in creating the positive emotions of customers and consequently trust restoring when customers experience unfavorable events in the multichannel context. Based on an empirical survey of smart phone users, the results showed that brand users' that develop initial trust of telecom operators tend to transfer their trust to channel distributors; moreover, positive emotion has a mediating effect between trust repair and trust. Krom (2015) evaluated the significance of innovation driven online entrepreneurship as well as the impact of innovation on brand trust, customer satisfaction and brand loyalty in the extent of service innovations. Global online entrepreneurship was explored on a theoretical basis and correlation and regression analyses were used in order to evaluate the impact of the innovations of Google on brand trust, customer satisfaction and brand loyalty. According to the research findings, brand trust and customer satisfaction have a direct and positive relationship with brand loyalty. Musleh (2015) investigated the extension of the unified theory of acceptance and use of technology (UTAUT) model to online shopping. Trust was found to have a significant positive impact on the attitude towards online shopping and actual online shopping. Elmorshidy et al. (2015) empirically examined factors affecting live chat customer support in Kuwait. The results showed a positive impact of attitude on the intention to use live chat support. Paul and McDaniel (2014) examined the relationship between interpersonal trust and virtual collaborative relationship (VCR) performance in a study of 10 operational telemedicine projects in health care delivery systems. Their finding of a positive association between integrated interpersonal trust and performance not only yields the strongest support for a relationship between trust and VCR performance but also contradicts prior research. This discussion leads to the following hypotheses:

H6: Trust in LSC services in the organizational Intranet positively influences employees' attitude towards using LSC.
H7: Trust in LSC services in the organizational Intranet positively influences employees' intention to use these services.

Attitude

The social psychology literature on behavioral research has established attitudes as important predictors of behavior and behavioral intention. (Göckeritz, 2010). Arora and Rahul (2017) empirically examined the impact of trust on online shopping attitude among women shoppers in India in an attempt to explain how trust in online shopping impacts attitude and what is the impact of online shopping attitude on online shopping intention. Results showed that trust impacts significantly online shopping attitude. The study also showed that that online shopping attitude has a positive impact on online shopping intention. Cheng (2013) empirically examined consumer attitudes toward the use of and consumer behavioral intention to use a Radio Frequency Identification (RFID) door security system at Taipei Arena Ice

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Land. The results showed that attitudes toward using these systems have a significant positive impact on behavioral intentions to them. In a study by Elmorshidy et al. (2015), factors affecting live customer support chat in Kuwait were examined. The result showed that attitude of using live support chat has a significant impact on behavioral intentions to use this system. Yushkova and Feng (2017) examined the determinants of the intention to bring mobile phones for recycling. Using structural equation modeling, the study confirmed that attitude, social norms, and knowledge contribute positively and significantly to the intention to bring phones for recycling. Lee et al. (2015) investigated the relationship between attitudes towards using mobile application services and customer satisfaction. Attitudes have proven to be the most significant factor for customer satisfaction and compatibility. This discussion leads to the following hypothesis:

H8: Attitude towards using LSC services in the organizational Intranet positively influences employees' intention to use these services.

Subjective Norms

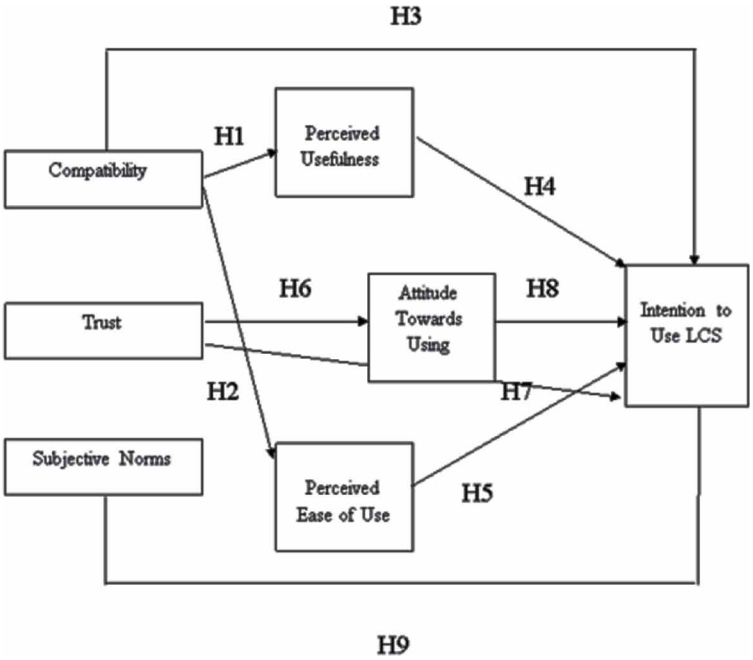
Subjective norm refers to users' perception of whether other important people perceive they should engage in the behavior (Elmorshidy et al., 2009). Diddi (2017) explored the role of values and norms towards consumers' intentions to patronize retail apparel brands engaged in corporate social responsibility (CSR). Data were collected via a web-based survey from a national sample of 407 US consumers. Findings revealed that moral norms, subjective norms, and attitudes were all important predictors of US consumers' intentions to patronize retail apparel brands engaged in CSR. Deng (2013) conducted a survey to examine the impact of subjective norms, behavioral attitude and perceived behavioral control on ethical purchase intention with 445 consumers selected by random sampling in Wuhan City, China. Results based on a structural equation model showed that behavioral attitude, subjective norms and perceived behavioral control had significantly influenced on ethical purchase intention of the respondents, with subjective norms being the strongest predictor of ethical purchase intention. Xiao et al. (2015) investigated the linear and nonlinear relationships among the concerned variables in electronic repository adoption. The results showed the perceived behavioral control which is a critical part of the planned behavior theory is not a significant predictor to electronic library adoption, while the subjective norms and attitude are the two significant predictors. Sang-Yon and Mi-Ryang (2013) examined the attitudes and perceptions of teachers toward the adoption of and intention to use Smart Education, more specifically the relationship between intention to use Smart Education and the consequential effect factors. The results of the study showed that attitude, subjective norms, teacher efficacy, resistance to class, and organizational citizenship behavior, respectively, affect intention for using Smart Education. Aghamolaei et al. (2012) examined fish Consumption in a Sample of People in Bandar Abbas, Iran to test the Application of the Theory of Planned Behavior. Multiple regression analysis revealed that attitude, subjective norms, and perceived behavioral control significantly predicted intention to eat fish. This discussion leads to the following hypothesis:

H9: Subjective norms of LSC services in the organizational Intranet positively influences employees' intention to use these services.

Based on the discussion above and our research model is illustrated in Figure 1.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Research model



RESEARCH METHODOLGY

In this section we discuss our sample acquired in the state of Kuwait, how the survey questionnaire was developed and distributed as well as the different scales adopted for perceived usefulness, perceived ease of use, perceived compatibility, subjective norms, perceived trust, attitude and the intention to use scale.

Sampling

The sample selected for this study was the employees using LSC services in organizational Intranets in Kuwait. Kuwait is a small oil company with a small population. Public and private companies there have access to the latest advanced technology pertaining to computes, internet-bases applications and internal communications networks including intranets. It The population of employees in Kuwait is around 1,800,000 individuals. A total of 500 questionnaires were distributed to employees at 11 private and 7 public organizations totaling 18 organizations. Of those 18 organizations combined, we divided the destitution equally between 6 large organizations, 6 medium organizations and 6 small ones. We emphasized the confidentiality of responses in the cover letter. We have received a total of 427 surveys by the deadline, 38 questionnaires were excluded because respondents did not complete the questionnaire appropriately. The final sample size was 389, which represents a 77.8% response rate. The sample size is 2.2% of the population which is a representative sample size.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Measures

The questionnaire developed to measure the variables of the study used a five-point Likert scale. The five-point Likert-type scale was used to increase response rate and response quality along with reducing respondents' "frustration level (Buttle. 1996).

Also, a five-point scale rather than a seven-point scale was chosen because it becomes possible to compare reliability coefficients with other research using five-point Likert Scales. (Saleh, & Ryan 1991). Finally, the literature suggests that a five-point scale appears to be less confusing and to increase response rate (Bouranta et al., 2009).

The perceived usefulness, perceived ease of use and attitude constructs were adopted from Davis (1989). The perceived compatibility scale was adopted from Wu and Wang (2005). The subjective norms scale was adapted from Al-Gahtani et al. (2007). The perceived trust scale was adapted from Kim et al. (2008). The intention to use scale was adapted from Ajzen (1991). The first part of the questionnaire was designed to obtain some demographic information including gender, age, and type of organization that the responder belongs to. Table 2 shows the demographic profile of the respondents.

Table 2. Demographic profile of respondents

Measure	Items	Frequency	Percent
Gender	Male	274	70.4
	Female	115	29.6
	Total	**389**	**100**
Age	16-19 years	0	0
	19-22 years	67	17.2
	23-25 years	140	35.9
	Above 25 years	182	45.9
	Total	**389**	**100**
Organization Type	Private	11	61
	Public	7	39
	Total	**18**	**100**
Organization Size	Large	6	33.3
	Medium	6	33.3
	Small	6	33.3
	Total	**18**	**100**

RESEARCH FINDINGS/RESULTS

Measurement Model

Model testing can be carried out using measurement model if it is reliable and valid. In this case, the reliability of measures and their convergent and discriminate validity can be verified. Fornell and Larcker

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(1981) suggested three criteria for verifying convergent validity: the factor loading for individual items is more than 0.50, the average variance extracted (AVE) are above 0.50 and the composite reliability (CR) of all the constructs is above 0.80. As shown in table 3, all three criteria were met, and thus, convergent validity of the measurement model is verified. For confirmation of validity of data Cronbach Alpha is calculated and as shown in it was in all the constructs above 0.90, which is higher than the minimum acceptable value of 0.60 as suggested by Nunnally (1978).

An exploratory factor analysis on SPSS was carried out to explore the variables of the research model. All the proposed constructs loaded on single component. AMOS v.16 was used to assess the validity and reliability of the data. The proposed model consisted of 26 items describing seven constructs: Perceived usefulness, perceived ease of use, perceived compatibility, perceived subjective norms, perceived trust, attitude and intention to use.

Table 3. Confirmatory factor analysis, validity analysis, and reliability test results

Concept	Item	Estimate	Average Variance Extracted (>0.50)	Composite Reliability (>0.80)	Cronbach Alpha (>0.60)
Perceived Usefulness	PU1	0.817			
	PU2	0.835			
	PU3	0.856	0.751	0.938	0.939
	PU4	0.823			
	PU5	0.874			
Perceived Ease of Use	PEU1	0.789			
	PEU2	0.745	0.765	0.942	0.953
	PEU3	0.759			
	PEU4	0.813			
Perceived Compatibility	PC1	0.836			
	PC2	0.784	0.747	0.933	0.947
	PC3	0.773			
	PC4	0.816			
Perceived Subjective Norms	PSN1	0.813			
	PSN1	0.834	0.742	0.958	0.955
Perceived Trust	PT1	0.841			
	PT2	0.847	0.774	0.948	0.931
	PT3	0.863			
	PT4	0.856			
Attitude	ATT1	0.877			
	ATT2	0.869	0.789	0.953	0.952
	ATT3	0.874			
	ATT4	0.843			
Intention to Use	IU1	0.843			
	IU2	0.854	0.762	0.931	0.949
	IU3	0.851			

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

To assess the discriminate validity of the constructs, product moment correlations between the variables was conducted as shown in Table 4 below. This was to assess the associations among the eight constructs constituting the model. All the correlation coefficients were significant which show that the constructs have a high degree of relation to each other.

Table 4. Discriminate validity of constructs (correlation analysis)

Construct	PU	PEU	PC	PSN	PT	ATT	IU
PU	1						
PEU	0.773	1					
PC	0.312	0.836	1				
PSN	0.426	0.32	0.824	1			
PT	0.362	0.369	0.382	0.836	1		
ATT	0.402	0.311	0.478	0.323	0.785	1	
IU	0.476	0.463	0.593	0.365	0.462	0.879	1

Structural Model Analysis / Hypotheses Testing

Structural Equation modeling was applied next to investigate the relationships among the research variables and the standardized path coefficients for confirmation of the hypotheses proposed. As shown in Table 5, the measurement model test presented a good fit between the data and proposed measurement.

Table 5. Overall fit measurement / model evaluation

Measure	Suggested Value	Observed Value
Root mean square residual (RMR)	< 0.05	0.043
Comparative fit index (CFI)	> 0.9	0.961
Goodness of fit index (GFI)	> 0.9	0.974
Normed fit index (NFI)	> 0.9	0.977
Non-normed fit index	> 0.9	0.968
Root mean square error of approximation (RMSEA)	< 0.05	0.369

Path coefficients are standardized versions of linear regression weights which can be used in examining the possible causal linkage between statistical variables in the structural equation modeling approach. The standardization involves multiplying the ordinary regression coefficient by the standard deviations of the corresponding explanatory variable: these can then be compared to assess the relative effects of the variables within the fitted regression model. Table 6 shows the results of the hypotheses testing indicating the Standard Path Coefficients, T-Values, Significance and whether each hypothesis was supported or not.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Hypotheses testing results

Hypothesis	Standard Path Coefficients β	T-Values	Significance	Supported
H1: PC to PU	0.325	7.562	$p < 0.001$	Yes
H2: PC to PEU	0.334	7.785	$p < 0.001$	Yes
H3: PC to IU	0.271	6.394	$p < 0.001$	Yes
H4: PU to IU	0.347	7.452	$p < 0.001$	Yes
H5: PEU to IU	0.336	7.526	$p < 0.001$	Yes
H6: PT to ATT	0.328	7.426	$p < 0.001$	Yes
H7: PT to IU	0.326	7.681	$p < 0.001$	Yes
H8: ATT to IU	0.386	7.684	$p < 0.001$	Yes
H9: PSN to IU	0.287	7.453	$p < 0.001$	Yes

PC: Perceived Compatibility; PU = Perceived usefulness; PEU = Perceived ease of use; PT = Perceived trust; ATT = Attitude; PSN = Perceived subjective norms; IU = Intention to use.

PC has a significant positive effect on PU ($\beta = 0.325$), and thus hypothesis H1 is accepted, PC has a significant positive effect on PEU ($\beta = 0.334$), and thus hypothesis H2 is accepted, PC has a significant positive effect on IU ($\beta = 0.271$), and thus hypothesis H3 is accepted, PU has a significant positive effect on IU ($\beta = 0.347$), and thus hypothesis H4 is accepted, PEU has significant positive effect on IU ($\beta = 0.336$) and thus hypothesis H5 is accepted. PT has a significant positive effect on ATT ($\beta = 0.328$), and thus H6 is accepted, PT has a significant positive effect on IU ($\beta = 0.326$), and thus hypothesis H7 is accepted, ATT has a significant positive effect on IU($\beta = 0.386$), and thus hypothesis H8 is accepted, PSN has a significant positive effect on IU ($\beta = 0.287$), and thus hypothesis H9 is accepted.

Discussion of Results

In this section, the results of the study are compared to previous studies related to factors affecting live support chat in an organizational context only. Our study revealed that perceived usefulness of LSC has a positive impact on intention to use these services. This is confirmed by previous study (Glass & Li, 2010). The results also showed that perceived ease of use of LSC has a appositive impact on intention to use these services. This is confirmed by previous studies (Ceccucci et al., 2010; Glass & Li, 2010). The results of study also revealed that perceived compatibility of LSC has a significant positive impact on intention to use these, which conforms to other studies about live support chat (Ceccucci y et al., 2010; Luo et al., 2010). The study further released that perceived subjective norms of LSC has a positive impact on intention to use these services, which also conforms to previous studies related live chat support (To et al., 2008; Glass & Li, 2010; Shih & Fan, 2013). The results also revealed that perceived trust in LSC has a positive effect on intention to use these services as confirmed by previous studies about live support chat (Ajjan et al., 2014). Finally, the results showed that attitude towards using LSC has a significant positive effect on intention to use these services, which conforms to previous studies about live support chat (Peskal et al., 2010; Ceccucci et al., 2010).

CONCLUSION

Theoretical Contributions

At the theoretical level, this study filled out a research gap by empirically investigating the factors that affect LSC service in the context of organizational Intranets. Few researchers have empirically examined the factors affecting LSC at the individual level (Ilk et al., 2012; Elmorshidy, 2013; Elmorshidy et al., 2015), and some researchers explored the determinates of LSC in an organizational context and how it affects employees. (Zhang & Fjermestad, 2008; Ou et al., 2010; Licoppe, 2010). This makes this research among the first studies to attempt do that. The results of this study also showed that several specific factors have a positive effect on intention to use LSC in an organizational context. These factors are perceived usefulness, perceived ease of use, perceived compatibility, perceived subjective norms, perceived trust, and attitude.

Implications for Practice

At the practice level, understanding the factors that influence LSC should be useful to developer and designer of LSC services and especially those who develop it in the Intranet of organizations. The study provides critical success factors as seen by the users (employees) of the organization that can make LSC services more customized to their needs, flexible and responsive. Organizations can also benefit from the findings of this study when developing their digital business strategy so it can accommodate LSC services. This should increase work efficiency, save time on solving problems, and strengthen employees' knowledge through sharing valuable information through these organizational instant chat services.

Limitations and Future Research

This study has a number of limitations. First, the study is limited in terms of the sample size and selection. The study focused on employees at private and public organizations in the state of Kuwait. The study did not focus on the type of business of these organizations (e.g. agricultural, industrial, technology). We recommend that this study be replicated with a focused approach that classifies organizations according to the type of business to explore how LSC is viewed and used in these organizations (according to their line of business). The second limitation is that this study was done only in Kuwait. To increase the external validity of the study, it is highly recommended to apply it again in organizations in other parts of world. Another limitation is that this study examined factors affecting LSC use in an organizational context only. We recommend that future research expand to examine factors affecting LSC in other contexts, which will also help increase both the internal and external validity of the study. Another limitation is that this study used cross-sectional data rather than longitudinal data. This means it focused more on observing respondents' behaviors rather than changes in behavior. Therefore, further research is encouraged to use longitudinal data to further explain the relationship between the variables of the study. Finally, this study used a quantitative approach to examine the factors affecting LSC in an organizational context. Using both quantitative and qualitative approaches will strengthen the analysis of the relationship between variables and will provide enhanced and better results that can prove the findings of this study.

APPENDIX

Table 7. Survey questionnaire

Construct	Item	Measure	Source
Perceived Usefulness (PU)	PU1	Live chat support is useful in solving my problems	Davis (1989)
	PU2	Live chat support is useful in increasing my productivity because I have more time to work on other issues	
	PU3	Live chat support is useful in increasing my effectiveness in finding ways to solve my problems	
	PU4	Live chat support is useful in making my problems getting solved easier	
	PU5	Live chat support is useful in solving my problem more quickly	
Perceived Ease of Use (PEU)	PEU1	Live chat support is easy to use	Davis (1989)
	PEU2	Live chat support is easy to learn	
	PEU3	Live chat support makes it easy for me to become more skillful in dealing with my problems	
	PEU4	I feel I have control over the use of live chat support	
Perceived Combativity (PC)	PC1	Using live chat support is compatible with all aspects of my work	Wu and Wang (2005)
	PC2	Using live chat support is completely compatible with my current situation	
	PC3	Using live chat fits well with the way I like to work	
	PC4	Using live chat support fits into my work style	
Perceived Subjective Norms (PSN)	PSN1	My friends who are important to me think I should use live chat support	Al-Gahtani et al. (2007)
	PSN2	My superiors/advisors who are important to me think I should use live chat support	
Perceived Trust (PT)	PT1	I believe the technologies supporting the live chat support system are reliable all the time	Kim et al. (2008)
	PT2	I believe the technologies supporting the live chat system are secure all the time.	
	PT3	Overall, I have confidence in the technology used in live chat support	
	PT4	Live chat support has the ability to reliably solve my problems over the Intranet	
Attitude (ATT)	ATT1	I like using live chat support	Davis (1989)
	ATT2	I feel good when I use live chat support to solve my problems and inquiries	
	ATT3	Overall, my attitude towards live chat support is favorable	
	ATT4	I strongly recommend other to use live chat support.	
Intention to use (IU)	IU1	I intend to use live support chat at work	Ajzen (1991)
	IU2	I intend to use live support frequently chat at work	
	IU3	Given that I have access to live support chat, I would definitely use live support chat

Chapter 42
Mobile Commerce Technologies and Management

Kijpokin Kasemsap
Suan Sunandha Rajabhat University, Thailand

ABSTRACT

This chapter reveals the prospect of mobile commerce (m-commerce); m-commerce and trust; m-commerce, privacy, and security issues; m-commerce adoption and technology acceptance model (TAM); and the significant perspectives on m-commerce. M-commerce is used for business transactions conducted by mobile phones for the promotional and financial activities using the wireless Internet connectivity. M-commerce is the important way to purchase the online items through online services. The main goal of m-commerce is to ensure that customers' shopping experience is well-suited to the smaller screen sizes that they can see on smartphones and tablets. Computer-mediated networks enable these transaction processes through electronic store searches and electronic point-of-sale capabilities. M-commerce brings the new possibility for businesses to sell and promote their products and services toward gaining improved productivity and business growth.

INTRODUCTION

Recently, the emergence of wireless and mobile networks has made possible the admission of electronic commerce (e-commerce) to mobile commerce (m-commerce), which is defined as the buying and selling of commodities, services, and information on the Internet through the utilization of mobile handheld devices (Lee, Hu, & Yeh, 2009). M-commerce technology is widely acknowledged as the next business format and its emergence has changed the business landscape (Faqih&Jaradat, 2015). M-commerce is of growing interest for vendors and customers and with that its importance within the combination of marketing and distributing channels (Möhlenbruch, Dölling, & Ritschel, 2010). The wide utilization of m-commerce includes the applications in banking, shopping, ticketing, entertainment, event management, and education (Gupta, Muttoo, & Pal, 2016).

E-commerce is the business that is transacted by transferring data electronically, especially over the Internet. (Kasemsap, 2016a). Through e-commerce, the cost for the entrepreneurs to sell their products can be saved and diverted to another aspect of their business (Kasemsap, 2016b). Both m-commerce and e-commerce applications have been enhanced by social networking sites, such as Facebook, Twitter, and LinkedIn (Lin & Lu, 2015). Social commerce is recognized as the commerce activities mediated by social media (Curty & Zhang, 2011). In social commerce, people explore the commerce opportunities by engaging in a collaborative online environment (Curty & Zhang, 2011). Organizations should accommodate and energize mobile users and design changes to their social networking sites to facilitate interaction and information sharing (Heinrichs, Lim, & Lim, 2011). Secure, reliable, and economical modes of payment play a critical role in the successful implementation of m-commerce (Lu, Yang, Chau, & Cao, 2011).

Advances in wireless technology have increased the number of people using mobile phones and accelerated the rapid development of mobile service conducted with these devices (Wang, Lin, &Luarn, 2006). M-commerce emerges as the ubiquitous technology among the existing wireless payment mode (Arora, 2016). Smartphones penetrate business and consumer markets, and mobile applications have engendered an innovative market (Keith, Babb, Lowry, Furner, &Abdullat, 2015). In order to attract more m-commerce users, companies and managers need to carefully consider elements (e.g., subjective norm, cost, risk, and enjoyment) that relate more to individuals' roles from both social and consumer perspectives (Zhang, Zhu, & Liu, 2012).

This chapter is based on a literature review of m-commerce. The extensive literature of m-commerce provides a contribution to practitioners and researchers by revealing the applications and implications of m-commerce in order to maximize the business impact of m-commerce in the digital age.

BACKGROUND

Development in the number of the Internet and telecommunications users since the late 1990s has provided companies with new ways to conduct business and exchange information through the development of the e-commerce market (Charbaji, Rebeiz, & Sidani, 2010). M-commerce is the new trend in business transactions (Hu, 2009) and the Internet-enabled smartphones become very popular these days (Hu, Zuo, Kaabouch, & Chen, 2010). Products are recommended to users based on their browsing behavior on the new mobile channel as well as the consumption behavior of heavy users of existing channels, such as catalogs and the Internet (Liu & Liou, 2011). Consumers use smartphones in their shopping experiences, such as browsing for product information and consulting friends before buying online (Ozuem & Mulloo, 2016). When shopping with a virtual catalog, customers can select products which meet their requirement concerning price range (Pierre, 2009).

Mobile devices, such as smartphones, tablets, and e-books readers, are gradually replacing traditional personal computers as the main method of accessing the Internet, organizing the widely deployed 3G/4G telecommunication technologies (Miao & Jayakar, 2016). Through m-commerce, users receive the large volumes of commercial messages (Wang, Hong, Xu, Zhang, & Ling, 2014). The evolution has triggered an increase in the use of mobile phones to conduct m-commerce and mobile shopping on the mobile web (Liou & Liu, 2012). M-commerce makes networks more productive by bringing together voice, data communication, and multimedia services (Wang, 2007). Regarding mobile shopping, the use context is

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

found to have the mediating role between time saving and satisfaction as well as between mobility and satisfaction (Kim, Chung, Lee, & Preis, 2015).

The rapid development of information technology enables the increasing numbers of consumers to seek and reserve products online first and then consume them in brick-and-mortar stores (Xiao & Dong, 2015). Guillén et al. (2016) indicated that the rapid growth of social networks has led many companies to use mobile payment systems as business sales tools. M-commerce environments are characterized by the high complexity, including myriads of technical and organizational aspects (Veijalainen & Weske, 2003). It is necessary to investigate how to design and develop m-commerce applications to ensure the successfulness of their deployment (Binsaleh & Hassan, 2013). Mobile voice service and innovation experience of mobile data services affect subscribers' consumption intention greatly; subscribers' perceived ease of use and brand experience can affect the subscribers' attitude toward mobile data services (Qi, Li, Li, & Shu, 2009).

PRINCIPLES AND PRACTICES OF MOBILE COMMERCE

This section provides the prospect of m-commerce; m-commerce and trust; m-commerce, privacy, and security issues; m-commerce adoption and TAM; and the significant perspectives on m-commerce.

Prospect of Mobile Commerce

The proliferation of mobile devices has created many opportunities for m-commerce (Chen, 2012), and mobile phones serve a wide variety of customers as the multi-sided platforms (Campbell-Kelly, Garcia-Swartz, Lam, & Yang, 2014). While the traditional PC access to the Internet continues to be vital for exploiting the advantages of the Internet, the mobile access appears to attract more people because of flexible accesses to the Internet in the ubiquitous manner (Sumita & Yoshii, 2010). Mobile phones are the global communication and business devices (Eze & Poong, 2016). Many mobile applications can have a much larger impact on the emerging economies than those of the developed world (Patel, 2006).

The advent of m-commerce is a natural phenomenon of the wireless convergence (Moqbel, Yani-De-Soriano, & Yousafzai, 2012). M-commerce applications have two major characteristics: mobility and broad reach (Ngai & Gunasekaran, 2007). In today's digital economy and the extended enterprise paradigm, mobility is on the rise (Godbole, 2006). Regarding mobility, m-commerce users can conduct business through mobile devices in real time. With m-commerce, users can be reached at any time through mobile devices (Ngai & Gunasekaran, 2007). Access to multiple wireless networks leads to the high transaction completion probability even when individual wireless networks do not offer the continuous access (Varshney, 2007). Smartphone users can access the Internet and search information more easily with built-in keyboards, which allow for the rapid data entry regarding m-commerce applications (Okazaki & Mendez, 2013).

Group-oriented m-commerce services are likely to be transaction-oriented with the significant monetary value of business transactions (Varshney, 2008). The challenges in the group-oriented m-commerce services include how to provide group management for m-commerce users who may even experience connectivity problems; how to support transaction performance, such as reliability; how to charge for transactions and other business model and strategies issues for wireless service providers; and user issues including adoption, training, and trust issues (Varshney, 2008). Secure multicast is a key element

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of m-commerce infrastructure toward supporting the group-oriented m-commerce applications, such as mobile auctions, product recommendation systems, and financial services (Eltoweissy, Jajodia, & Mukkamala, 2008).

In the m-commerce schemes, the users can use their electronic identity to register, such as mobile phone number and e-mail address. Then, they can use their mobile phones to conduct transactions at any place and any time (Han et al., 2016). When m-commerce users move between the stores, the mobile information which includes user identification, stores, and item purchased are stored in the mobile transaction database (Argade & Chavan, 2015). In m-commerce, companies provide location based services to mobile users, who report their locations with a certain level of granularity to maintain a degree of anonymity (Chorppath & Alpcan, 2013). Yu et al. (2011) indicated that mobility management, which includes location management and handoff management, is essential in cellular wireless networks to provide service to mobile users.

Examples from the financial sector include the instant funds transfer (mobile banking) and share trading (mobile brokerage) (Petrova, 2008). Mobile banking is an emerging application of m-commerce that can become the additional revenue source to both banks and telecommunications service providers (Kim, Shin, & Lee, 2009). Mobile banking helps fulfill the personal banking requirements and provides the location-free conveniences. Mobile brokerage services allow mobile phone users to conduct financial transactions using client software at any place and any time (Lin, Lu, Wang, & Wei, 2011). Compared with online brokerage services and telephone-based trading services, mobile brokerage services have unique features, such as ubiquity and mobility (Lin et al., 2011). Investors are able to conduct financial trades without spatial and temporal constraints (Kleijnen, Ruyter, & Wetzels, 2007).

As advertisers increasingly rely on mobile-based data, consumer perceptions regarding the collection and use of such data becomes of great interest to scholars and practitioners (Eastin, Brinson, Doorey, & Wilcox, 2016). Knowing the demographic patterns in m-commerce usage activities can assist companies in improving their mobile advertising strategies (Chong, 2013). Over the years, mobile messaging has become an essential method of communication through the utilization of the Internet and mobile networks (Yow & Mittal, 2008). Perceived network externalities contribute to higher perceived usefulness and perceived ease of use and significantly affect the m-commerce-related short message service (SMS) adoption (Lu, Deng, & Wang, 2010). Smartphone-based mobile advertising is a promising marketing approach, especially in retail and point-of-purchase environments (Atkinson, 2013). Trust in SMS advertising and subjective norms contribute to the intention to use (Zhang & Mao, 2008).

This section is dealing with the prospect of m-commerce and the next section is dealing with m-commerce and trust. With the proliferation in the mobile device usage, most of the business activities are centered around mobiles. Realizing the importance of m-commerce app development, most of the business organizations implement their own mobile app to offer a better service to their customers. Businesses are lining up to build m-commerce app dedicated to access their products and services.

Mobile Commerce and Trust

Trust over the mobile platforms is more critical due to the open nature of wireless networks (Nilashi, Ibrahim, Mirabi, Ebrahimi, & Zare, 2015). The high level of trust enhances the transaction and eliminates perceived risks regarding m-commerce adoption (Li & Yeh, 2010). Despite the popularity and potentials of m-commerce, real m-commerce activities in many developing countries remain low due to the users concern about trust issues (Chong, Chan, & Ooi, 2011). One of the main reasons for low intention is

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

uncertainty that leads to lack of trust that has been challenged and surveyed by the network capabilities (Siau & Shen, 2003) and interface design (Lee & Benbasat, 2003). The link between interface design and ease of use holds an important approach to motivating the females' utilization of m-commerce (Okazaki & Mendez, 2013).

The website with a greater level of trust is often associated with a higher degree of purchase intentions and higher customer retention rate (van der Heijden, Verhagen, & Creemers, 2003). M-commerce has empowered consumers to easily switch from one website to another at any time (Peng, Quan, & Zhang, 2013). By using websites for promotion and sales, companies are able to sell to markets (Falk & Hagsten, 2015). McKnight and Chervany (2001) claimed a well-designed mobile website with considering the ease of navigation and useful links to other websites give customers adequate information for making purchase decisions. Chae and Kim (2003) stated that limitation in system resources (e.g., small screens in mobile device and reduced multimedia processing capabilities) can constrain the development of trust in m-commerce.

Many predictors of trust have been acknowledged in previous literature, such as perceived site attribute (Wakefield, Stocks, & Wilder, 2004) and website quality (Koufaris & Hampton-Sosa, 2004). With the aid of information technology, a virtual shopping environment is effective in prompting the transactions and has implications of building trust (Li & Yeh, 2010). Trust plays a crucial role in the formation of dependent relationships represented by online transactions (Li, Pieńkowski, van Moorsel, & Smith, 2012). The user's trust behavior toward m-commerce application is composed of three constructs: using behavior, reflection behavior, and correlation behavior (Yan, Dong, Niemi, & Yu, 2013). However, the difficult task for m-commerce is to ensure consumers' trust by making them feel comfortable with wireless transactions (Kapoor, 2016).

This section is dealing with the prospect of m-commerce and trust and the next section is dealing with m-commerce, privacy, and security issues. With the increased usage of smartphones, there are a sizable reduction in the number of people browsing through desktops. Everyone prefers to purchase using a mobile app as they find it more interesting and quick. Consumers are greatly benefited from a mobile app because they need not search for the discounted products and latest collections. Trust is very important to make consumers satisfied with m-commerce application. Most online consumers are intensely aware that various websites are collecting and storing their private information. The more consumers trust companies, the more willing they are to share data regarding m-commerce application.

Mobile Commerce, Privacy, and Security Issues

Mobile devices are at a higher security risk due to the large amount of critical financial and personal data available on them (Adlakha, 2016). In m-commerce, consumers are facing higher security and privacy risks because of the data transaction in a wireless environment (Chong, Darmawan, Ooi, & Lin, 2010). It is essential to consider the maximum security that is an urgent precedence in the m-commerce applications (Nilashi et al., 2015). For example, a secure credit-card mechanism for m-commerce should securely protect the corresponding transactions and personal information (Leu, Huang, & Wang, 2015).

Security is the most important issue for the widespread deployment of m-commerce applications based on mobile agent technology (Muñoz & Maña, 2011). Mobile agent is the technological promising product that can migrate from host to host toward autonomously performing tasks (Chang & Lin, 2006). Most of the existing solutions (e.g., execution tracing, code obfuscation, encrypted code execution, and partial result encapsulation) mainly cover the security threats of mobile agents' code (Shibli, Masood,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Ghazi, & Muftic, 2015).For secure communications in public network environments, various three-party authenticated key exchange (3PAKE) protocols are proposed to provide the transaction confidentiality and efficiency in the m-commerce environments (Yang & Chang, 2009). Cryptography is one of the most important elements in providing security for the m-commerce systems (Hu, Hoang, & Khalil, 2011).

Regarding security issues, the secure m-commerce system must have the following properties: confidentiality, authentication, integrity, authorization, availability, and non-repudiation (Lee, Kou, & Hu, 2008). The authentication and authorization of transactions are generally performed by certification authority (Pai &Wu, 2011). For business transactional tasks, both perceived usefulness and perceived security affect the user's intention to utilize m-commerce (Leonard, 2010). Chen (2008) indicated that perceived transaction, perceived transaction rapidity, privacy, and security concerns are the important antecedents of consumer intention to m-commerce.

Big data is a data management system that can reduce the need for storage facilities for data and lower the computational requirements for various sectors (Kasemsap, 2016c). When the adoption of big data is properly aligned to the business, existing governance structures can be easily adjusted to address security, assurance, and general approach to embracing new technologies (Kasemsap, 2017a). Regarding privacy perspectives, consumers' mobile information privacy concerns are largely rooted in the big data-related ecosystem (Cleff, 2007).

Nowadays, digital consumer is no longer entirely anonymous since every form of communication virtually generates the data that can be collected, aggregated, and analyzed (Wessels, 2012). Information gathered for one purpose can be readily retrieved for another, and the possible linkage between mass amounts of aggregated data about an individual makes collected data personally identifiable (Eastin et al., 2016). Okazaki et al. (2009) indicated six determinants toward individuals' information privacy concerns in online settings (i.e., data collection, data control, unauthorized secondary use, improper access, location tracking, and awareness related to these practices).

This section is dealing with the prospect of m-commerce, privacy, and security issues, whereas the next section is dealing with m-commerce adoption and technology acceptance model. Consumers' lack of trust remains the largest single obstacle to growth in the mobile content and commerce industry. M-commerce brings the new challenges in providing information security as information travels through multiple networks often across wireless links. Online businesses must strive to maintain open privacy policies along with strong encryption and authentication processes in order to stay ahead of the attackers. When consumers feel free of risks and have high level of trust in the intention to utilize m-commerce, they actually adopt it.

Mobile Commerce Adoption and Technology Acceptance Model

The technology acceptance model (TAM) has been used for several years to predict the attitudes and behaviors of consumers of mobile services (Molina-Castillo & Meroño-Cerdan, 2014). TAM can be applied to predict consumer's acceptance to the mobile telecommunication innovations in the presence of network externalities (Wang, Lo, & Fang, 2008). TAM with trust is utilized to explore the influence of perceived ease of use and perceived usefulness in mobile shopping on customers' attitudes and behavioral intention to use, mobility, convenience, and information richness, characterized by m-commerce (Chen & Lan, 2014).

Jung et al. (2009) considered TAM, content, and cognitive concentration in a mobile TV service for the potential users who intend to use and suggested that cognitive concentration has the critical impacts

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

on consumer's intention to subscribe the mobile TV service. Luarn and Lin (2005) extended TAM with three factors (i.e., credibility, self-efficiency, and financial cost) and examined consumer's behavioral intention to use the mobile banking. User satisfaction is recognized as one of the useful measures of m-commerce system success (Wang & Liao, 2007). Thus, it is an essential to identify the user requirements for establishing the m-commerce system standards (Büyüközkan, 2009). Brand loyalty is the tendency of customers to keep buying the same brand of a particular product instead of trying other brands (Kasemsap, 2016d). Users' continuance usage and satisfaction on m-commerce can promote brand loyalty (Hew, Lee, Ooi, & Lin, 2016).

The adoption of mobile phones tends to lead to an increase in the demand for mobile content (Eze & Poong, 2016). Investigating mobile technology adoption is the growing interest for technology developers, marketing managers, and researchers (Su & Adams, 2009). Network designers, service providers, and application developers must carefully take the considerations of various users into account to provide better services and attract them to m-commerce (Pedersen, Methlie, & Thorbjornsen, 2002). The importance of perceived value in customer decision making is well-recognized (Pihlström & Brush, 2008).

Perceived compatibility, perceived usefulness, and perceived ease of use are positively related to the behavioral intention to use m-commerce (Halbach & Gong, 2013). Position experience, cognitive style, and computer self-efficacy are the major factors that can predict the suitability of applying mobile devices (e.g., personal digital assistants and tablets) technology for insurance tasks (Lee, Cheng, & Cheng, 2007). Users greatly value the accuracy of the reliability and simplicity of the m-commerce applications (Choi & Stvilia, 2013). Retailers have increased their investment in mobile shopping channels to deliver the content, products, and promotions to customers toward enhancing m-commerce adoption (Liu & Liou, 2011).

Adopters perceive smartphones as both an essential device in which to invest money and a symbolic device to signal their affiliation and timely technology adoption (Kim, Chun, & Lee, 2014). The ability of customer value and the lock-in mechanism are important for maintaining online shoppers through m-commerce (Shih, 2012). Mobile users perceive their devices as a method to quickly assist them in their offline activities, such as rapid communication, price checking, and location-related services (Narang & Arora, 2016). Location-based m-commerce incorporates location-aware technologies, wire-free connectivity, and locationalized web-based services to support the processing of location-referent transactions (Wyse, 2009).

Significant Perspectives on Mobile Commerce

M-commerce is the modern technology which has enhanced the way of conducting business transactions (Sharma, 2016). M-commerce is an emerging discipline involving the use of mobile computing technologies (Faqih &Jaradat, 2015). M-commerce developers and practitioners must understand consumers' perception of m-commerce applications in order to better design and deliver the m-commerce service (Chen, Li, Chen, & Xu, 2011). In m-commerce, the consumer has to deal with the online vendor and the payment provider (Köster, Matt, & Hess, 2016). Consumers order products and services at the online vendor and provide personal information (e.g., financial data) to the mobile payment provider (Köster et al., 2016).

Mobile technologies allow companies to execute various activities toward communicating with current and potential customers (Kapoor, 2016). Modern marketers have the capability to aggregate multiple information sources to establish personal profiles about consumers, which can be used to nar-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

rowly target individuals with various forms of marketing communications (Vesanen, 2007). The benefits of m-commerce include the easy purchase process, instant updating of the information, improved customer satisfaction, cost savings, new opportunities for business, and the ability for the customer to use it everywhere (Kasemsap, 2016e). M-commerce offers the convenience of personalized marketing on mobile phones (Kaur & Malhotra, 2016).

Mobile tasks performed on handheld devices significantly challenge the m-commerce developers to adopt new methods and design guidelines that take into account contextual variations in the m-commerce environments (Chan & Fang, 2003). Companies and businesses have opted to adopt m-commerce to offer more widespread services to their different stakeholders (Alfahl, Sanzogni, Houghton, & Sandhu, 2014). The increased mobile usage is a clear example of the growth of mobile services as it offers the significant opportunities as the independent sales channel toward deserving special attention from researchers (Aldas-Manzano, Ruiz-Mafe, & Sanz-Blas, 2009).

Business process management is the development and control of processes used in a company, department, and project to ensure they are effective (Kasemsap, 2017b). With the emergence of business process management, the focus has shifted to the development of electronic services that integrate business processes and that diversify the functionalities available to customers (Chou & Seng, 2012). Due to its inherent characteristics (e.g., ubiquity, personalization, flexibility, and dissemination), m-commerce promises business market potential, great productivity, and high profitability (Siau, Lim, & Shen, 2003). The Internet-enabled mobile handheld devices are one of the most important components of the m-commerce system, making it possible for mobile users to directly interact with m-commerce applications. Enhancing users' ability and their sense of personal control can promote the use of future mobile text-based applications and services (Mahatanankoon & O'Sullivan, 2008).

There are various barriers that obstruct the proliferation of m-commerce, such as mobile devices inefficiency, lack of consumer's trust, incompatible networks, poor network coverage, limited bandwidth, low speed, lack of security, high cost of handsets, and lack of awareness (Gupta, 2016). Poor usability of mobile Internet sites for commerce activities is the major obstacle for the adoption of mobile solutions (Chan & Fang, 2009). Even though providing a mobile site for mobile device users may greatly enhance their news reading experience, many news organizations cannot afford the additional option due to limited funding and staffing resources (Lu, Wang, & Ma, 2013).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of m-commerce will provide the potential opportunities for future research. M-commerce describes online sales transactions that use wireless electronic devices, such as handheld computers, mobile phones, and laptops. These wireless devices interact with computer networks that have the ability to conduct the online merchandise purchases. Customer satisfaction is significant because it provides marketers and business owners with an effective marketing metric that they can utilize to manage and improve their businesses (Kasemsap, 2016f). Creating positive customer experiences across all stages of the product's life cycle drives higher satisfaction among current customers, which builds customer loyalty (Kasemsap, 2016g). An examination of linkages among m-commerce, customer satisfaction, and customer loyalty would seem to be viable for future research efforts.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Consumer attitude influences the way consumer thinks and it is important for the marketers who study it to understand how consumer behaves toward increasing business profit (Kasemsap, 2017c). The use of social media has created the highly effective communication platforms where any user, virtually anywhere in the world, can freely create the content and disseminate this information in real time to a global audience (Kasemsap, 2017d). Social media offers a chance to redefine the delivery of service to customers, thus changing the way they think about a company's brands while considerably lowering service costs (Kasemsap, 2017e). Web mining techniques can be applied with the effective analysis of the clearly understood business needs and requirements (Kasemsap, 2017f). Business process management is the development and control of processes used in a company, department, and project to ensure they are effective (Kasemsap, 2017g). Considering the relationships among m-commerce, consumer attitude, social media, web mining, and business process management would be beneficial for future research directions.

CONCLUSION

This chapter highlighted the prospect of m-commerce; m-commerce and trust; m-commerce, privacy, and security issues; m-commerce adoption and TAM; and the significant perspectives on m-commerce. M-commerce is used for business transactions conducted by mobile phones for the promotional and financial activities using the wireless Internet connectivity. M-commerce is the important way to purchase the online items through online services. The main goal of m-commerce is to ensure that customers' shopping experience is well-suited to the smaller screen sizesthat they can see on smartphones and tablets. Computer-mediated networks enable these transaction processes through electronic store searches and electronic point-of-sale capabilities.

M-commerce brings the new possibility for businesses to sell and promote their products and services toward gaining improved productivity and business growth. There are a number of business opportunities and grand challenges of bringing forth viable and robust wireless technologies ahead for fully realizing the enormous strength of m-commerce in the digital age and thereby meeting both the basic requirements and advanced expectations of mobile users and providers. The successful future of m-commerce depends on the power of the underlying technology drivers and the attractiveness of m-commerce applications toward obtaining m-commerce adoption.

KEY TERMS AND DEFINITIONS

Electronic Commerce: The business conducted through the use of computers or other electronic appliances without the exchange of paper-based documents.

Internet: The worldwide computer network that provides information on many subjects and enables users to exchange the messages.

Mobile Commerce: The business that is conducted on the Internet through the use of mobile phones or other wireless, handheld electronic devices.

Mobile Payment: The point of sale payment made through the wireless devices, such as a mobile phone and personal digital assistant.

Smartphone: The mobile phone with the highly advanced features.

Technology: The purposeful application of information in the design, production, and utilization of products and services.

Technology Acceptance Model: The most widely utilized model to predict and explain the user acceptance of information technology.

Transaction: The exchange of products or services between a buyer and a seller.

This research was previously published in Mobile Platforms, Design, and Apps for Social Commerce; pages 197-218, copyright year 2017 by Business Science Reference (an imprint of IGI Global).

Chapter 43
The Impact of Emergent Technologies in the Evolutionary Path for M-Commerce

Justino Lourenço

Polytechnic Institute of Gaya, Portugal

ABSTRACT

M-commerce is a fast-growing opportunity and is acting as an innovative lever for achieving the purpose of increasing sales while better interacting with the clients. Simultaneously, several emerging technologies have appeared in the market and promise to change the current m-commerce paradigm. Therefore, this chapter plans to explore a set of new trend technologies that can plan to build a more efficient relation between the consumer and the m-commerce platform. This study conducted surveys with several market players like marketers and IT leaders to understand their point of view, perceive the relevance and impact of these emergent technologies in m-commerce, identify resistance and challenge points to the proposed change, and look how to allow cohabitation between this new e-commerce paradigm and the traditional physical trade. The main novelty of this study is the inclusion of multiple points of view on the evolution of m-commerce which will allow companies and citizens to perceive the impact of emerging technologies in the future of m-commerce.

INTRODUCTION

Nowadays, any relevant small or big company has a digital presence, even if most part of cases there isn't a delineated strategy in the business (Razavi et al., 2010). The consumers interact each day more with different forms of digital presence for a business. The companies, on another hand, show their presence in the social networks, threw: digital advertising across multiple platforms; websites, mobile applications and even in gaming solutions. The shopping environment, in a few decades, has moved from physical stores to hybrid solutions that merge physical space with the digital world, creating the new concept of Omnichannel presence (Frazer, 2014).

One strong concern of a company is the overall exposition of the business and product over the Internet. The consumers with a behavior pulled by the trend movements, convenience, the proliferation of portable digital devices (that provide easy and fast access) – are feeling the wealth of the new commerce solutions. So the focus is in: strong, clear and clean presence over all the digital channels. Another relevant aspect is developing innovative approaches for gaining new customers while keeping strong ties to the first time visitor to an m-commerce provider. The loyalty client programs should always be appealing, trendy and effective to maximize its goal: keep a consumer connected to a product, solution or brand.

Currently, there is a new blurring between online (e-commerce), and offline retail as described in (Rogojanu et al., 2018) as we planned to propose in our solution. This new technological framework means a powerful tool that can and should be used. This preliminary study plans to provide a reflection of a possible evolutionary path to all the previous topics that were presented. The proposed solution binds the future physical store and m-commerce in this new era. The introduction of new technologies that will enable a stronger tie with consumers such as: Chatbot with Artificial Intelligence (AI) agents for interacting, improved location based services, Virtual Reality (VR) and Augmented Reality (AR) for creating a new product showroom and improving the loyalty programs with the support of a Blockchain structure – are the key for the proposal. By conducting surveys with several market players such as marketers and IT leaders we will understand their point of view, resistance to the proposed change, the relevance of the new proposed solution and the timetable proposed for their implementation.

The manuscript is organized as follows: Initially, a conceptual analysis of the characteristics and properties of emerging technologies with potential impact on m-commerce is performed, respectively: (i) Location Based Services (LBS); (ii) 5G and Delay Tolerant Networks (DTN); (iii) Bluetooth and Near Field Communications (NFC); (iv) Augmented Reality (AR) and Virtual Reality (VR); (v) Internet of Things (IoT); (vi) blockchain; and (vii) Artificial Intelligence (AI). The adopted methodology and the main results of the study are presented below. After that, some solutions and recommendations are presented in the adoption of these emerging technologies in the context of the m-commerce paradigm. Finally, the conclusions of the work are presented and some indications are given about relevant future works in this field.

BACKGROUND

Location Based Services (LBS)

The geographic position of the consumer is of great relevance to the retail activity, in particular for a conventional store. The crucial elements to LBS have been a two-way wireless data communications link

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

plus navigation data inputs to permit a screened flow of information from LBS data servers. Today, most LBS system designers consider the fusion of Global Position Satellite (GPS) receivers and cellular phone services the starting point. This approach provides geo-detection in outdoor scenarios. In fact, for a local store is very relevant to understand when a consumer is in the near vicinity of the store, but also when he is the near region. So, it would be relevant to define a zone in the vicinity of the retail store where all possible consumers will get a notification for promoting a visit to the store. (Kanfade et al., 2018)

The GPS approach is widely used for LBS in outdoor solutions. However, it is not suitable for solutions in the scenario of non-line-of-sight (NLOS) and several indoor scenarios where there is almost no coverage of GPS signal. In indoor locations, the common approach uses the support of Wi-Fi for position detection. The common solution involves the Wi-Fi fingerprinting to obtain the desired accuracy. This preliminary solution has the cost of a new calibration for each environment. A new approach is an adaptive Wi-Fi trilateration-based indoor localization system that provides better accuracy, as required for the LBS (Yi et al., 2018). A new model that can improve accuracy relies on a range-based localization algorithm in non-GPS positioning systems. This model adopts the enhanced Kalman Filter (KF) and Centroid Localization Algorithm that can manipulate noise signal from raw Received Signal Strength Indicator (RSSI). The solution shows that the proposed model improves the accuracy percentage by more than 80% (Din et al., 2018).

Xiaojie Zhu (2019) resumes the newest challenges in LBS architectures, which include: minimizing resources consumption, improving accuracy while taking into consideration the user privacy with all UE regulations.

5G and Delay Tolerant Networks (DTN)

The evolution of mobile network from 2.5G to 3G, enabled the development of e-commerce to the m-commerce contributes to the fact that mobile commerce activity will be the important content in the future mobile application.

A reliable and fast path for all the information sharing with a mobile user is a relevant topic for the existence of a comfortable channel between the retail store and end user. According to Kshetri (2018), Wi-Fi and 5G networks will play a relevant role in this achievement. The 5G will enable the creation of better and strong ties in e-commerce, but will also new business models within the next upcoming years (Yrjölä, et al., 2018).

The 5G will open a new world that will provide a wide range of interesting requirements, such as enhanced mobile broadband, massive machine type communications, ultra-reliable communications, low latency and support an increasing number of connected devices. Chochliouros, et al. (2017) advocate that 5G will provide the chance for the development of an all-new architecture proposed, aiming to attend several operators/service providers and "engage" them in a modern multi-tenant ecosystem that will work as leverage for the 5G adoption.

Even with the future coverage of 5G and Wi-Fi some undesirable scenarios may occur like the lack or low network coverage and temporary congestion of the networks. In fact, the numbers of devices that work with the support of a network do increase exponentially every year. The combination of AI, machine learning and contextually rich, real-time data streams delivered by IoT sensors and networks, along with the conventional data services that will be powered by the 5G can cause problems in the network in particular in the early days of 5G. A strategy of building classes of tolerance to the delay can provide an interesting approach in order to avoid congestion of the network, as the traffic dramati-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

cally increases. Some future and current services can have their communication delayed in a convenient way without harming their function (Esaki, 2009; Penurkar, 2015). The DTN networks also referred as Disruptive Tolerant Networks can play a relevant role in a smart prioritization of the traffic generated in severe communication scenarios.

A DTN is a network designed so that intermittent or disruptive communication scenarios will not avoid communication between nodes, there are several aspects for an adequate design on this approach: (i) support of fault-tolerant methods and technologies; (ii) even under severe communication scenarios, it is expected that a computer, machine, electronic system or network to maintain limited functionality even when a large portion of its data has been destroyed or rendered inoperative; (iii) fast recover from network attacks; and (iv) minimize latency even under severe communications.

Bluetooth (BT) and Near Field Communications (NFC)

In the scenarios of short-range and proximity communications, the BT and NFC technologies surely will play a relevant role.

Bluetooth is a specification for a wireless network in a Persona Area Newark (PAN) context. The BT solution enables the data exchange between a bundle of heterogeneous devices as long as they have BT support. The previous versions of BT enabled proximity detection systems with the support of the measurement of the signal strength. It was possible with relatively poor accuracy the distance in meters, but it was not possible to determinate the direction. A new desired feature is now present in BT 5.1, announced by the Bluetooth Special Interest Group: the development a positioning service that can now determine the direction of a BT signal that enables the precision detection of a BT device with the accuracy down to the centimeter. This feature is possible after the introduction of two innovative methods: Angle of Arrival (AoA) and Angle of Departure (AoD).

Several new features will improve BT efficiency such as (Monteiro et al., 2012; Alshahrani & Walker, 2013): (i) faster connections with low power; (ii) connection broadcast improvements; (iii) near filed communication that can be spread on point of sales (PoS), security check-in, eTickets and small range data transfers.

NFC is promising in providing a reliable and secure paired communication between two distinct devices. Because it is only reliable within a short-range scenario, the risks of interception are very low, so it can be considered a secure solution. In comparison with other available technologies – it achieves physical-level security but sacrifices convenience.

Public Digital Terminals (PDT) can also perform a relevant role in the commerce activity. There is a wide array of PDTs that a common person uses frequently including Automated Teller Machines (ATM), interactive kiosks, and self-service kiosks. The widespread use of smartphones and tablets has given rise to the next generation of m-commerce solutions. A proximity-aware solution to address the security, privacy and accessibility concerns when using PDTs will be of great relevance (Misbhauddin & Alshamari, 2018).

The issue of tracking a customer using Bluetooth Low Energy (BLE) is also presented in the literature (Shende et al., 2017). In this proposed solution the tracking of the clients is supported by BT beacons that are set up in the retail shop vicinity. Taking into consideration the clients' profile, supported by their shopping patterns and purchase behavior, a mobile application can detect the presence of a client and send this information to a server. The server can react worth personalized offers for the client, this way stimulating the process of shopping in a retail store.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The short-range technologies such as NFC can be used instead of SMS and/or Bluetooth solutions. It can be demonstrated that NFC, compared with SMS technology, is faster and more convenience (Alshahrani, 2013). The NFC is a common support for contactless payment systems that has several proposed mechanism to grant the necessary security (Chattha, 2014; Oleh Zolotukhin, 2018; Raza et al., 2018). Some studies also present the future relevance of wireless technologies such as Zigbee (Dhauta & Kapoor, 2017). It can demonstrate the eligibility of a BT solution for several use cases, such as: (i) localization/route of a client in a small area; (ii) payment support; (iii) broadcast of promotion or sales of products; and (iv) interaction with products.

Augmented Reality (AR) and Virtual Reality (VR)

The main definition of VR is supported by the definition of the concepts virtual" and reality. The "virtual" is a near reality concept that is applied in VR. The VR can create a reality that will bring a new reality approach for a human. On the other hand: AR can be defined as an enhanced version of the reality created with the support of technology to add more information to an image or scenario.

Both technologies can be used to enhance the experience of a consumer with a product (Hah et al., 2011; Stoyanova et al., 2013). Some approaches propose this enhancement experience in a stadium: amplifying the sports contents, invisible to the spectators and generating new content on-screen to improve the sports experience in a stadium (Hurwitz & Jeffs, 2009).

The m-commerce experience also can be improved. The idea is to offer to consumers a similar experience to a visit in a physical retail shop. The technology that supports the sort can also build an interesting bundle with AR, the AR experience can be triggered by the presence of the consumer (Erışık, et al., 2015). A shopping assistant prototype with simulated augmented reality information that helps the consumer in the process of online shopping or in a physical store is also a proposal (Ganapathy et al., 2011). Some studies also suggest that provide a comparison between a normal shopping experience and an AR shopping experience are promising (Stoyanova et al., 2015). Integrating LBS solutions, previously discussed, with AR also improves the shopping effectiveness (Adhikari, et al., 2015).

The AR is a very interesting approach, but pushing one step forward to VR, the final virtual scenario created around a product or service will grant a much better experience to the consumer: the combined experience of a 3 environment of a physical store with the e-commerce characteristics will, for sure, enhance the consumer desire, this way, bringing a new push o the e-commerce (Yu & Pan, 2012; Speicher, 2018). The interaction and the visual impact of a store virtual scenario on a phone will be the key in the future (Jayachandran et al., 2017; Kang, 2017).

Internet of Things (IoT)

The IoT is a connected ecosystem between all the existing computing devices with mechanical and digital machines, objects, animals or people that with the support of a unique identifier are enable to transfer directly data without human-to-human or human-to-computer interaction.

The IoT will sure have a relevant role in the future concept of a retail shop or even in an e-commerce solution, the chance to generate physical interactions will be of considering relevance. A smart shopping platform including four components, location of everything component, data collection component, data filtering/analyzing component and data mining component is proposed in (Rezazadeh et al., 2018).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The association, as described in the definition of IoT, of each product with a unique identifier can provide a way to build virtual assistants, real-time stock update and product georeferencing (Chen et al., 2010). The solutions addressed will also face new security issues, as described in: (Li et al., 2017),

Blockchain

The term Blockchain derives from the structure of the digital records that are linked together in a single list, named as chain. The main purpose of Blockchain was to store transactions made by the crypto currencies, such as bitcoins, but it has several other applications. Blockchain technology may pull a variety of industries, including e-commerce, financial services, real estate, supply chain management, health care, academia and more.

Besides the possible scenario of a transaction on an e-commerce site that is supported by crypto currency, the technology that supports Blockchain can have other applications. In order to provide several bottlenecks in the current loyalty programs such as lost paper coupons, payback process complications, setup of several mobile applications and the grow of heterogeneous solutions the Blockchain technology can provide a new approach. It may provide more usability for users, use only digital content and more detailed information can be gathered from the companies' perspective (Bülbül & İnce, 2018).

The issue of managing a queue in shopping that supported by e-commerce has the big challenge of delivering requests from clients that can be queued, also, can be solved more efficiently with the support of Blockchain (Yadav et al., 2018).

Artificial Intelligence (AI)

The AI topic is by definition the ability for a digital system to perform a task commonly associated with intelligent human beings. The AI is a strong topic of research in several areas: manufacturing; traffic control; eHealth systems; traffic management; risk management; car industry; efficient stock optimization, gaming, and several others. This trend has an evolutionary path, and nowadays AI technologies is becoming a path for e-commerce solutions: topics such as keyword advertising, multivalent decision making, social networks management, information retrieval, semantic web, logistic management, and clients support with the help of Chabot's support (Zeng, et al., 2008).

The presence of AI tools and solutions suffered a recent but important evolution: the initial monolithic system became a distributed artificial intelligence, known as intelligent agent technology (Galuszewska & Sahut, 2003). One strong goal in the e-commerce scenario is the chatbot technology for consumer contact and support. Some bibliographic sources provide studies about future chatbot integration in commerce services (Pricilla et al., 2018; Rychalska et al., 2018; Albayrak et al., 2018; Santoso, et al., 2018). Furthermore, the AI concept is also a relevant topic of research in providing a new and efficient tool in optimizing the commerce and e-commerce ecosystem and is in detailed described in the literature (Rao et al., 2018).

E-commerce is an example of a large-scale multi-agent system. Consequently, it is of great relevance to study and integrate a model and devise an implementation for the large-scale knowledge sharing solution with the support of Bayesian networks, game theory and network security, as proposed in: (Ai-Ping et al., 2006). An electronic platform is a possible application of such a concept. Such a platform can be viewed as a collection of software agents: customer, search engine, catalog, manufacturer, dealer, and bank agents, all of them on the Internet and the need and ability to negotiate with each other efficiently.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

It is clear that the retail organizations much have a clear vision about the customer's needs, expectations and forms of fulfillment and this task can be achieved through the support of AI and the ability to store and analyzing an encoded sentiment data based on feedbacks considering the context and the environment. (Rogojanu et al., 2018).

FOCUS OF THE ARTICLE

The chapter plans to provide a reflection about an evolutionary path for both: physical retail shop and electronic commerce platform. Nowadays, it is common for a commerce business to have presence in a multichannel: shoppers are not only shopping online, but are in fact merging their online and offline shopping practices. Several technologies can enable a much richer experience in optimizing the entire ecosystem. Among these technologies are included VR/AR, BT, LBS, IoT, AI, and Blockchain. This study collects the opinion from marketers, IT leader and other professionals in the IT sector on the relevance and impact of emergent technologies in m-commerce. It also intends exploring how it would be possible to allow cohabitation between this new e-commerce paradigm and the traditional physical trade.

This study adopts a quantitative methodology through the use of a questionnaire. Quantitative research is a statistical study that aims to describe the characteristics of a study, numerically assessing the hypotheses formulated considering a research problem. The information is typically collected through a structured questionnaire with clear and objective questions. According to Creswell (2018), the quantitative methodology is especially indicated to generate accurate and reliable measures that allow statistical analysis. The sample should also be large enough to enable a reliable statistical analysis. Additionally, Queirós et al. (2017) argue that in a quantitative survey it is especially important to look at the representativeness of the results that should be based on probabilistic criteria for sample selection.

The survey is organized into three dimensions (e.g., contextual, evaluative, and forecast) as depicted in Table 1. In the contextual dimension, an attempt is made to characterize the profile of respondents. For this purpose, information is collected on professional experience, company size, and the number of years of experience in e-commerce and m-commerce. Next, in the evaluative dimension, respondents are asked to classify the degree of relevance of six emerging technologies that have contributed to the evolution of the m-commerce paradigm. Finally, in the forecast dimension, respondents are asked about the impact of the technologies identified in the previous point on the shopping experience in a physical store, namely if the shopping experience in a physical store could be improved with the integration of those technologies.

In the contextual dimension, multiple choice boxes were used to get textual and numeric information. Instead, in the evaluative dimension, a multiple choice grid was employed. A Likert scale composed of five levels (i.e., 1. little importance to 5. great importance) was adopted for all questions presented in the evaluative dimension.

A total of 83 respondents was received and considered valid. The profile of respondents is detailed in Table 2. Two profiles of respondents stand out: marketing professionals and IT tech engineers. In total, these two profiles represent more than 60% of the sample. The size of the company is quite heterogeneous, with most respondents working in large enterprises followed by micro companies. The majority of the respondents have experience in e-commerce for more than 10 years. Although the e-commerce experience is quite significant, the number of years of experience in m-commerce is relatively low, and most respondents (43.4%) have less than 2 years of experience.

Table 1. Organization of the survey

Dimension	Variables	No. of items
Contextual	Professional occupation	4
	Size of the company	
	Years of experience in e-commerce	
	Years of experience in m-commerce	
Evaluative	Relevance: Virtual Reality / Augmented Reality	6
	Relevance: Bluetooth	
	Relevance: Location Based Services	
	Relevance: Internet of Things	
	Relevance: Artificial Intelligence	
	Relevance: Blockchain	
Forecast	Engagement	1

Table 2. Sample characteristics

Variable	Absolute frequency	Relative frequency
Professional occupation		
CEO	13	0.157
CTO	8	0.096
Marketing	19	0.229
IT Tech	31	0.373
Other	12	0.145
Size of the company		
Micro companies (less than 10 employees)	20	0.241
Small enterprise (10 to 49 employees)	18	0.217
Medium-sized enterprise (50 to 249 employees)	12	0.145
Large enterprise (250 or more employees)	33	0.398
Years of experience in e-commerce		
Less than 2 years	19	0.229
Less than 5 years	17	0.205
Less than 10 years	22	0.265
More than 10 years	25	0.301
Years of experience in m-commerce		
Less than 2 years	36	0.434
Less than 5 years	28	0.337
Less than 10 years	12	0.145
More than 10 years	7	0.084

The results of the questionnaire are presented in Table 3. The findings allow us to conclude that artificial intelligence and the internet of things are the two technologies that present the greatest potential impact on the evolution of the m-commerce paradigm. These two technologies simultaneously register the highest mean and mode. The importance of these two technologies in the evolution of m-commerce is also highlighted in the literature. Huang & Rust (2018) emphasizes the role that artificial intelligence as a source of innovation in services with particular impact on the retail sector. In the same vein, Chen (2018) proposes the use of artificial intelligence models that can exploit information about customers stored in a database, namely for marketing and sales services. On other perspectives, the IoT promises to bring disruptive innovation to the online purchasing process. The traditional purchasing process based on a human-human or human-thing model evolves into a thing-thing model. In a model based on IoT, a great diversity of devices is connected as wearables, smart-watches, or fitness trackers that allow creating smart applications (Turban et al., 2017). In fact, IoT is related to other technologies that increment the potential impact in the retail sector, such as big data, M2M, cloud computing and industry 4.0 (Almeida, 2017). Despite the unequivocal benefits of the introduction of IoT associated to the increase of commercial transactions and improving the online shopping experience, several challenges persist, especially in terms of security, technological dependence, integration and social impact on employability (Bena et al., 2017).

The analysis of the standard deviation allows us to deepen our knowledge about the behavior of the variables under study. Bluetooth, VR/AR, and Blockchain are the technologies that registered the most divergent opinions. The impact of these technologies is seen in a relatively heterogeneous way, and the opinions on their impact on the evolution of m-commerce differed significantly. Bluetooth proved to be essentially useful in an initial phase of m-commerce adoption, but it has gradually lost importance in recent years due to the evolution of NFC and ZigBee (Pine, 2017). VR/AR is still very emerging technologies and whose practical application is still relatively little known by retailers, but which offers a lot of potential when combined with artificial intelligence (Smith, 2018). Finally, blockchain intends to significantly reduce trade costs by increasing transparency and facilitating process automation. However, several challenges still persist in its adoption, such as (Bodó et al., 2018; Ganne, 2018): (i) scalability; (ii) privacy and security; (iii) data standardization; (iv) legal validity; and (v) governance.

Table 3. Statistical analysis of the questionnaire

Variable	Mean	Mode	Std. dev.
Relevance: Virtual Reality / Augmented Reality	3.542	4	1.140
Relevance: Bluetooth	2.723	3	1.243
Relevance: Location Based Services	3.964	4	0.890
Relevance: Internet of Things	4.229	5	0.888
Relevance: Artificial Intelligence	4.289	5	0.904
Relevance: Blockchain	3.398	4	1.136

Table 4 shows a statistical hypothesis test considering the number of years of experience (YE) in m-commerce. ANOVA was applied to test the equality of the averages of the four groups of years of experience in m-commerce. For this purpose, a significance level of 0.05 was adopted and it was as-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

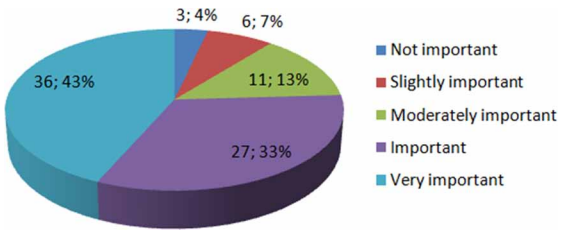
sumed that the errors are independent and come from a normal distribution with mean equal to zero and constant variance. A large p-value for the F-test means that the data obtained are consistent with the null hypothesis, and there is no evidence of a linear relationship or explain the variance of the dependent variable (relevance of each considered emergent technology). The results show that only the blockchain technology presents a value below 0.05, which indicates that the user groups with more years of experience in m-commerce consider that blockchain will have greater relevance in the development of m-commerce when compared to the junior users in m-commerce.

Table 4. Hypothesis test for the number of years of experience in m-commerce

Variable	Mean (YE < 2)	Mean (YE < 5)	Mean (YE < 10)	Mean (YE ≥ 10)	Prob > F
Relevance: Virtual Reality / Augmented Reality	3.333	3.607	3.667	4.143	0.341
Relevance: Bluetooth	2.722	2.821	2.833	2.143	0.624
Relevance: Location Based Services	4	3.893	4.167	3.714	0.704
Relevance: Internet of Things	4.139	4.214	4.417	4.429	0.744
Relevance: Artificial Intelligence	4.111	4.393	4.333	4.714	0.347
Relevance: Blockchain	3.083	3.393	4.167	3.714	0.029

Next, the study sought to explore the respondents' perception of the use of the above technologies in increasing shopping experience in a physical store. The information collected in Figure 1 is unanimous in considering that its impact should not be negligible. More than 75% of respondents considered that the impact of the use of these technologies on the shopping experience in a physical store is important or quite important. Only 3.61% of respondents mentioned that these technologies would not have any impact. These findings are aligned with the results of recent studies published in the literature, which refer that the incorporation of new technologies in a physical store positively affects both the experience and the buying intention (Foroudi et al., 2018; Mosquera et al., 2018). Additionally, Grewal et al. (2017) and Almeida (2018) mention the use of these technologies in fostering big data collection, contribute to a better analytical analysis of business profitability, and provide new insights and forecasts using predictive analysis models.

Figure 1. Impact of emergent technologies in the shopping experience at a physical store



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

SOLUTIONS AND RECOMMENDATIONS

A bundle of new technologies described in the previous session can and should be implemented in order to enrich the shopping experience. The inquiry results described in the previous section also validate the relevance of the solution that will be proposed in this section.

The authors believe in a merged and new approach: the physical store experience can be enhanced with the support of new technologies enabling a best advising and fitting between the consumer profile, product exhibition, and product advice. On the other hand, the e-commerce experience can and should be more similar as possible to a physical store shop. This means an enhanced overall experience for the consumer in both scenarios, real and virtual shopping. The solution is to combine actual technologies and integrate them with new trend technologies to achieve an optimized solution.

The LBS solutions can be a major key aspect in the new proposed model in several ways. Nowadays, the LBS solutions are already integrated into a premature form. The proposal is to turn LBS into a key element in promoting shopping activity. But, new challenges arise, one of them is the new data regulation in Europe that takes into consideration the data privacy of each user, and should and will be taken into consideration in this proposal. (Tian, Liu, Wu, & Hu, 2017; Jung & Park, 2017)

Nowadays, the user can be informed about the existence in the vicinity of a retail shop that fits its typical customer behavior stored in its customer profile acquired in many forms. This information, at the moment, is broadcasted to promote a visit to a physical store, when the consumer is traveling in the vicinity. The new challenge is to acquire as much information as possible from a visitor/potential client taking into consideration the new regulations, in particular, in Europe: General Data Protection Regulation (GDPR). The UE has developed legislation concerning the protection of UE citizens with regard to the processing of personal data and on the free movement of such data. A new privacy concept called user-centric privacy framework (UPF) can be adopted in this particular solution: a user adapting system that follows the adaptable privacy statement that complies with best privacy practices and with the actual legal regulations; supported by privacy-enhancing technologies for single-user and group-based activities; provide user-controlled privacy considerations. (Garcia-Barrios, 2009)

The privacy of a citizen will be for sure, even, a more relevant discussion topic in the next years. A key factor for acquiring and maintaining new data from the clients is through the device's ID when connected to Wi-Fi, 4G/5G, mobile application login, and loyalty programs. Each day fewer consumers are comfortable about sharing their personal data. Several approaches are presenting different forms of dealing with the LBS issue and user protections: user identifiers are permuted at regular intervals to prevent identification based on statistical analysis of long time sequences (Takbiri et al., 2017); location privacy preservation protocol (Deb et al., 2010), and several others. The basic idea is to refer to a client with a unique identifier, not necessarily correlated with a name, address, email or any other sensitive personal data. The common approach of generating a consumer profile threw the data mining of conventional data as the user, email, professional occupation, age, and potential income will only be possible – with a clear authorization of the user, and even then – with restrictions. On the other hand, most users are leading their concerns to the data privacy issue and new privacy issues methodologies are presented, such as User-Tailored Privacy (UTP) to adapt Facebook's privacy features to the user's personal preferences (Knijnenburg, 2017; Namara et al., 2018) and several others mirroring the new concern and regulations.

In the actual state of technology it isn't feasible to track a mobile user without the need to acquire its personal data or identification, and e.g. if a user changes its connecting devices the data mining process used in the client's profile definition with AI tools can predict from the unknown new consumer if it

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

fits in a behavior type of a previously stored profile and with a good level of liability understand that this unknown client is in reality – a previous profile stored in the client's profile database or a new one. All of this can be achieved without interference in personal critical data and, consequently, it is not an irregular procedure taking into consideration the GDPR.

The effective loyalty programs will also be relevant for enabling the consumer to cooperate on sharing some useful data as presented in Chakraborty (2018) and Sumarliyanti et al. (2018). The loyalty program data, taking into consideration the authorized items supported by GDPR, can be stored in a blockchain structure for a group of retails, this way, using the benefits of this technology, such as: trust, transparency, security, and reliability of data processing. Also, it can be stated that a shared loyalty platform will mean less cost in building and supporting it.

The fast-growing of solutions supported in IoT can and will be a challenging issue in the near future (Liu et al., 2018). The ability to generate interactions between a user in a physical store and the shopper can be very promising. As an example, a user that stands near a exhibition stand of a product in a store can generate an relevant event: change in the lightning; sound message about the product; a VR-AR animation that starts for fully exploring the potential of a product or for collecting statistical metrics about the average time that a shopper stands looking for the product exhibition. The association of an IP address, smart capacity processing can promote the described interaction process. The technologies of Wi-Fi, Bluetooth, and NFC can be of great relevance for the determination of the client's position in the physical space of a store.

Machine learning (ML) is one of the main approaches to address the problem of big data mining. ML can enable the e-commerce ecosystem bringing self-innovate and improvement by accumulating prior knowledge (Rao et al., 2018). The data collected and processed with the ML tool will enable a much richer decision-making service for marketing strategy. This also means a better approach to the customer's expectation and needs (Rogojanu et al., 2018), enabling to overcome also the inefficacy of the customer behavior: the majority of the shoppers do not do the purchase in the first visit (Yeo et al., 2018).

The interaction between a client in a shopping process on a conventional approach or online can be more efficient with the introduction of a full support solution that could enable a much richer shopping experience. The customer could and should be advised in real time to enable a faster shopping time experience providing all the relevant information that the customer needs in the shopping moment. This important interaction solution can be supported by an intelligent conversational agent (CA). A CA also widely known as chatbots is a computer program to simulate the conversations between human and machine (Leong et al., 2017; Albayrak et al., 2018).

Enriching the shopping experience, while merging the experience of a retails shop experience with the electronic experience, is the emergent challenge. It should also be considered another relevant experience in an electronic shopping experience: the product visualization and interaction with the client in a common physical store. But we can also have referred that the physical experience of the shopper can and should be enriched with the ability to sense the product more in detail.

Nowadays, Virtual Reality (VR) and Augmented Reality (AR) are a new and extend existing customer experience: increasing interaction with user or equipment motion, applications have been strongly continuing to produce and reach more user experience target (Atalar & Özcan, 2017). The VR and AR solution can be understood as a process for overlaying virtual information of products on the real world (Li & Chen, 2010). With most of the information in the digital form and with the typical use of JPEG format as a form for enabling the visualization of the products – the JPEG AR standardization has been started in 2012, enabling the integration of images in an AR scenario – the JPEG committee enabled

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the development of a standard, JPEG AR (ISO/IEC 19710). This part is an extension of relevant JPEG standards with image-based AR application, which is ideal for AR application's behaviors.

The enrichment of the experience, keeping in mind the proposed evolutionary path for electronic and conventional shopping development, means bringing the AR/VR experience, as previously referred, to the physical store. The introduction of new hardware in-store will enable the desired enrichment: virtual mirrors and touch-screen digital signage - all integrated into a physical store, and often making use of shoppers own mobile devices, ranging from tablet PCs to smartphones, as described in Bodhani (2013).

On another perspective, this revolution will also affect the way we think about electronic commerce applications: visiting an electronic store can be a panoramic experience where visitors can select a product they are interested in and freely view the product from any angle by rotating the tablet or smartphone. Products can be displayed as if it were in the hands of the user by a photo-based augmented reality system (Photo AR), allowing comparison with other objects possessed by the user as described in: (Ohta et al., 2014). The 3D experience in an e-commerce store is also described in Khedwala et al. (2018). As a final remark in Chakraborty & Gupta (2017) that explored the factors impacting the adoption of augmented reality in online purchases in India, an important finding was identified, which concluded that people who are Gadget Lovers and those who prefer to buy online frequently were more likely to try Augmented Reality.

FUTURE RESEARCH DIRECTIONS

The introduction of several technologies and the new proposal for an evolutionary path for the e-commerce, taking into consideration a merging between the physical store and the electronic stores open a new bundle of new research topics for the near future.

The AR/VR conceptualization and implementation will push the mobile phones, tablets and other personal communication devices within the Personal Area Network (PAN) will be pushed to new features and more powerful integrations of AR/VT features. It will also be expected that new algorithms will perform more efficiently the files required to induce the new paradigm around VR/AR.

The challenge of using LBS is essentially in managing the compromising between the actual and future regulations around user privacy and the ability to keep on tracking the users in a more efficient way. The R&D challenges points to the determination with expected increasing accuracy the position of the customer. Nowadays we can easily spot a user in a store, but we need to spot a user near a product in a part of the store where user intervention should be as minimal as possible to be effective (e.g. we should expect the user to remember to turn on the Bluetooth on its device on entering a shopping zone).

The flow of data within the ecosystem of electronic commerce will increase with the introduction of the proposed solution. All new signaling will be used to spot, interact, promote, generate AR/VR objects and dealing with future loyalty platforms. A topic of research can be the definition of priorities in this big flow of information and in some cases implement DTN approaches to avoid special coverage areas, delays and congestion instants in the network. The application of the concept of an overlay network that can disseminate lower priority traffic will be a major concern, enabling a DTN solution.

A platform supported by LBS, IoT, AI, and Blockchain that collects and deals with relevant information about the shopper and the electronic commerce business should have an enhanced mechanism of security. Some studies should work around new proposals for hard secure algorithms that could be efficient even in elementary hardware modules that will build the censoring network, for example in a

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

product exhibition stand. In the topic of research of AI, the speed of processing can enable fast responses when, for example, a client is in the advising process to get the product that best fits his profile.

CONCLUSION

The proposed solution plans to describe a possible evolutionary path for electronic commerce solutions. During the chapter, it is clear that the authors believe in the introduction of several technologies with the focus to promote a better shopping experience, consequently better results for the m-commerce business. The results of the survey among professionals working in e-commerce and m-commerce showed that IoT and AI have greater potential in the context of the evolution of m-commerce paradigm. These technologies will play a crucial role in identifying the client, understand the client, advice and enrich the experience of "feeling" a product prior to the final and desired shopping act being done. Additionally, it was possible to identify that users with more years of experience in the adoption of m-commerce identify blockchain technology as offering greater relevance in the development of m-commerce than users with fewer years of experience.

The conventional activity of shopping in a physical store can also be improved by building new displays and interacting capabilities. Also new forms of building metrics about customer behavior around the new product exhibition and their impact in the number of visitors that leave the store with at least one purchase successfully. A key to the success of the proposed solution will be the interaction supported by IoT sensors and actuators around a product with the support of AI. This approach will keep on collecting data, processing it and elaborating strategies for maximize customer satisfaction.

The enrichment of the experience of navigating through an online store was also tooled into consideration. Again a solution of AR/VR combined with AI agents can promote the desirable merging between the two worlds: physical and electronic commerce platform. Additionally, the relevance of a trustful, reliable and easy-of-use loyalty program supported by the Blockchain technology was demonstrated that can optimize in a secure way the process.

KEY TERMS AND DEFINITIONS

Agent: Software developed to automate and perform a task on a network for the user.

Chatbot: Computer program that tries to simulate a human being in conversation with people.

General Data Protection Regulation (GDPR): Regulation for the protection of the data and identity of European Union citizens that started to be idealized in 2012 and was adopted in 2016.

Omnichannel: Communication and sales strategy between channels that organizations use to improve customer experience.

Personal Area Network (PAN): Computer network for interconnecting devices centered on an individual person's workspace.

Wi-Fi: Wireless network in which users can have access to the internet only by radio wave signal.

ZigBee: Set of specifications for wireless communication between electronic devices, with emphasis on low operating power, low data transmission rate and low implementation cost.

Chapter 44
Secure Payment Modes Technology for E-Commerce Applications

Niteesha Sharma
Anurag Group of Institutions, India

Adiraju Rao Prashanth
Anurag Group of Institutions, India

ABSTRACT

E-commerce refers to business and customers buying and selling products online. There are significant improvements in the areas of initiating sale of products, placing orders, making payments, and transfer of funds. This has led to a much better global economy and better living standards for all. While buying products online, it is essential to know the payment method that ensures authentication and also many other security issues. There are many payments modes available in market today. This chapter presents different protocols and its security issues that relate to a specific payment mode.

INTRODUCTION

Commerce is the most major aspect of any civilization. Improving Commerce can bring prosperity into all segments of society. In today's world there have been major changes to the commerce industry. The most important of it is the introduction of computers into the commerce industry. Computerization of commerce has taken the world by a storm. There are significant improvements in the areas of initiating sale of products, placing orders, making payments, and transfer of funds. This has led to a much better global economy and better living standards for all.

Payment started with the barter system centuries ago. Goods were exchanged directly between people in the barter system. The major drawback of barter system was that the buyer and the seller had to mutually like the goods that they had in surplus. This led to next generation of payment method called Commodity Money System. Here, the buyer would buy goods from the seller in exchange of some commodity in the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

form of gold, silver, corn etc. Commodity Money slowly evolved into standard of having paper notes at the exchange parameter. The cash payment method does not require the seller to like the commodity that he/she is going to receive in exchange for the goods. About 80 percent of all the transactions in the world are done through cash payment. The process is simple and there is no bank involvement. There is however an overhead of printing notes.

The cash payment method is very insecure. There is no record of the transaction maintained. There is a possibility for generating counterfeit notes. Cash Payment is mostly used for low-value payments. Check Payment is employed for making medium to high value payment. A record of the transaction is maintained at the bank at the cost of the transaction fee. However, it is not a guaranteed form of payment since the checks do not represent real time cash. There is a possibility that the checks could be turned down by the buyer's bank due to various reasons. As the volume of check processing started increasing, banks had to think about ways of improving the turn-around time for payment processing.

Problems of traditional processing system (Raj Garg, 2016):

- **Lack of Security:** It is because the consumer has to send all the confidential data on paper, which is not secured and encrypted.
- **Lack of Convenience:** Traditional Processing system requires consumer to send paper cheques duly signed by them before performing any transaction. This may lead to in convenience by consumers.
- **Lack of Time and Eligibility:** Not all the buyers may have the bank accounts.

E-commerce (electronic commerce or EC) is the buying and selling of goods and services, or the transmitting of funds or data, over an electronic network, primarily the internet. These business transactions occur either as business-to-business, business-to-consumer, consumer-to-consumer or consumer-to-business. The terms e-commerce and e-business are often used interchangeably. The term e-tail is also sometimes used in reference to transactional processes for online shopping.

Advantages of E-Commerce

The advantages of E-Commerce are as follows:

- E-commerce helps organization to provide better customer services.
- E-Commerce reduces paper work a lot.
- E-Commerce increased the productivity of the organization.
- E-Commerce provides option of virtual auctions.
- Customers need not to travel to shop a product thus less traffic on road and low air pollution.
- E-Commerce application provides user more options to compare and select the cheaper and better option.

Applications of E-Commerce

The applications of E-commerce are used in various business areas such as retail and wholesale and manufacturing. The most common E-commerce applications are as follows:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Marketing

E-commerce marketing is a practice of redirecting and guiding online customers to an e-commerce website and convincing them to buy the products or the services online.

E-Commerce Marketing can be divided in to two major actions: maintaining and driving the website traffic and optimizing the user experience. Both the factors are essential and failure of one result in undetermined success of other. Big commerce is the leading e-commerce platform for growing mid-market retailers.

Finance

Most of the financial companies have been using E-commerce to a large extent. The customers can check their online account statements, balance, transfer money to other accounts and also pay their bill through online banking or e-banking systems. As the main developing trend of e-commerce in finance realm, the finance trends provide many advantages like the funds circulation can be delivered to whole world quickly, improving efficiency, improving security, can connect more number of users and have instantaneous access to information.

Manufacturing

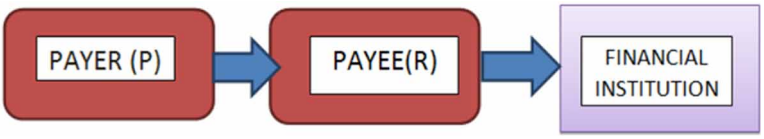
Manufacturing can be defined as a process of collecting the raw materials and then converting them into finished qualitative goods or products for the consumers.

In order to raise the profitability and also to improve the customer's service many companies/ manufacturers move their supply chain operations on to internet using an electronic exchange which is a forum where all the manufacturers, suppliers, customers buy and sell goods and also trade the market information. Also effective e-commerce lies in the ability to deliver a buyer-centric and engaging online experience that enables customers to interact and transact with the brand and allows manufacturers to reduce administrative costs, increase sales and improve brand loyalty. This is achieved by reducing costs.

Different Payment Modes of E-Commerce

Electronic Commerce industry is exploding at a fast pace. One of the key aspects of electronic commerce is payments. There are different methods to pay electronically. These can be through Credit Cards, Electronic Checks, Electronic Cash, Debit Cards, or Charge Cards.

Figure 1. Typical scenario of e-commerce system involves three types of actors



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Payer (P)/Consumer:** Payer transfers some money to his/her wallet.
- **Payee (R) / Merchant:** Payer transfers the withdrawn money to the payee's (R) wallet
- **Financial Institution:** A bank with whom both payer and payee have accounts.
- Main factors which help society to make use electronic payment systems are:
- **Decrease in Technology Cost:** Since the technology used in networks is being decreased day by day, the internet is becoming almost free everywhere.
- **E-Commerce is Secure:** The usage of secure electronic transaction ensures the security of financial transactions on internet.
- **Minimal Operational and Processing Cost, Time:** Due to reduced technology cost the processing cost of various commerce activities are becoming less with much more less usage of Paper and Time.
- **Increasing Online Commerce:** Considering the above two factors many Organizations are leading towards Online Commerce (Raj Garg, 2016).

E-Commerce involves trading using the latest electronic equipment and software between the sellers and the buyers. The trade in e-commerce is conducted in a slightly different way than the traditional trading. The first form of automated payments was to disburse salaries to employees from an employer's account. Gradually, the information revolution changed the outlook of the banking sector and computerized majority of the functions. This is achieved with the help of different E-commerce payment systems which is explained in detail in next section.

TYPES OF E-PAYMENT SYSTEMS

Bogdan-Alexandru URS (2015)presented the most used electronic payment systems are as following: Smart card-based e-payment system, online payment system, Mobile phone based payment system, E-Wallet Payment System and the E-Cheque Payment System. New payment types are continuously discovered and there are additional methods that exist or are being developed continuously each year.

Digital Cash

e-Cash or digital cash is purely software based, anonymous, untraceable, online token payment system, available on Unix, Windows as well as Macintosh platform (Rachna & Singh, 2013). Digital Cash entails the use of digital wallet where in it works as a system of purchasing cash credits in small amounts and storing them in the computer and using it for the electronic purchases. The digital cash numbers are unique and are issued by banks, money in your bank is converted into digital code. Also referred as e-currency, e- cash, e-money etc. Figure 2 represents e-cash processes in general:

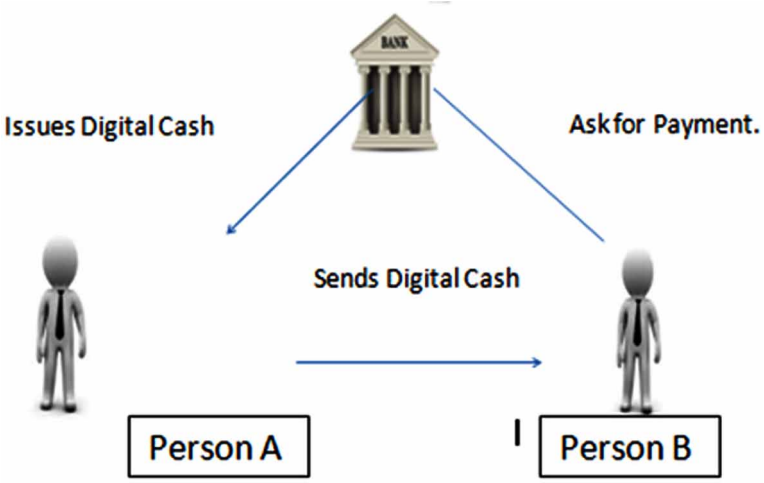
Security in E-Cash

Any E-cash system to be accepted, security is one of the prime concerns that need to be considered. The originality of the message being transferred among consumers, merchants and banks need to be secured to avoid any unauthorized individual intercepting or changing the content of the messages. In order to protect E-cash from such illegal activity, E-cash system must possess quality such as integrity,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

nonrepudiation and able to authenticate. All parties must know to whom they are dealing with, before engaging or committing in any transaction. Integrity comes in place where the message sent by consumers, merchants and banks must be intact when it reaches respective recipients. Razali (2002) discussed that once the integrity and authentication are achieved, consumers, merchants or banks could no longer deny the bank transactions.

Figure 2. The usage of digital cash



Credit Cards

There are two major organizations issuing 80% of the credit cards in the market today. They are:

- Visa International and
- MasterCard.

An overview of the credit card processing is depicted in the Figure 3.

- Card Issuer
- Financial Network
- Acquirer
- Card Holder
- Merchant

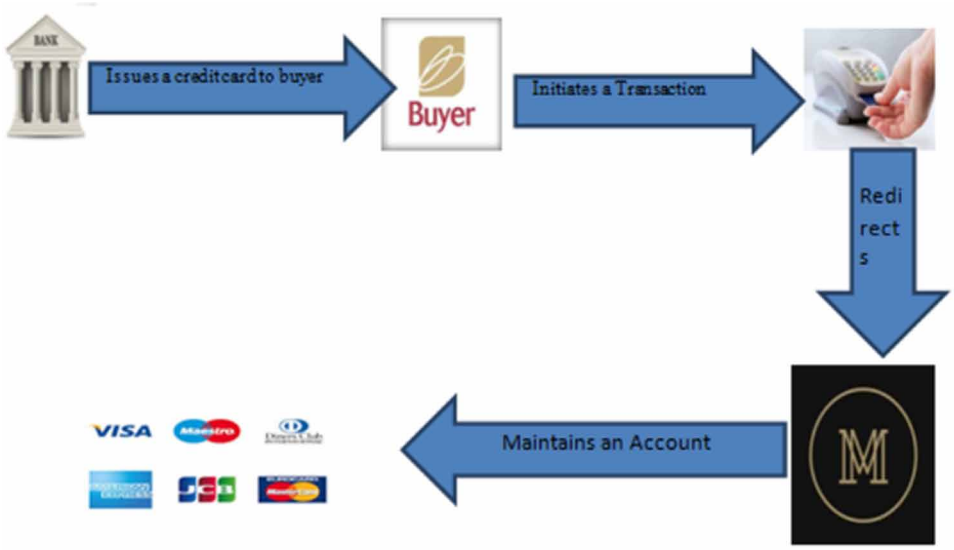
There are four main partners in a Credit Card transaction.

1. The Issuing Bank is the bank that maintains the account of the buyer and issues a Credit Card to the buyer. The issuing bank also sets a limit on the amount of purchases that can be made using the card and the percentage of interest on the unpaid portion of the bill.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. The cardholder is also known as the buyer in the transaction. The cardholder initiates a transaction.
3. The merchant is the seller of goods and services.
4. The merchant maintains an account with a bank or a financial institution known as the acquirer. Acquiring institutions contracts with merchants to enable them to accept credit card transactions and charges a certain percentage of fees for the transaction.

Figure 3. Entities in conventional credit card processing system



Credit Card Payment Process

A Credit Card Payment is a two-step process:

1. Authorization
2. Capture/Settlement

Authorization is a process in which the merchant verifies the cardholder's identification and credit limit. The merchant sends the credit card information like the card number, expiration date, and amount to the acquirer. The acquirer will forward the card details to the issuing bank via the existing financial network. The credit card issuer will either return an approval, decline or referral for the authorization request. If the transaction was approved, then the merchant can deliver the goods purchased to the buyer. A transaction can be declined for various reasons like unavailable credit, bad credit history, wrong address, etc.

Capture/Settlement is the process of actual transfer of funds from the cardholder's account to the merchant's account. It collects the money for the merchant after the goods have been delivered.

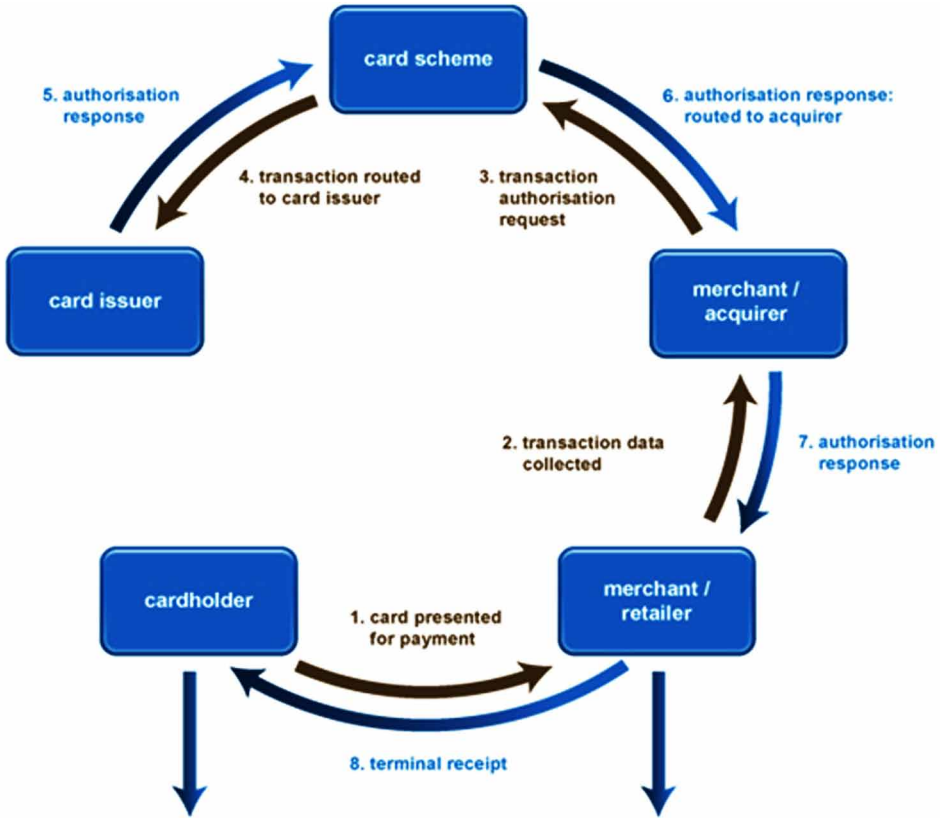
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Debit Cards

Debit card, like credit card is a small plastic card with a unique number mapped with the bank account number. It is required to have a bank account before getting a debit card from the bank. The major difference between debit card and credit card is that in case of payment through debit card, amount gets deducted from card's bank account immediately and there should be sufficient balance in bank account for the transaction to get completed. In case of credit card there is no such compulsion. Having restriction on amount being in bank account also helps customer to keep a check on his/her spending.

The Figure 4 demonstrates the usage of debit cards.

Figure 4. Debit card payment processing cycle



Smart Card

Smart card is again similar to credit card and debit card in appearance but it has a small microprocessor chip embedded in it, used to perform financial transactions. It has the capacity to store customer work related/personal information. Smart card is also used to store money which is reduced as per usage. Smart card can be accessed only using a PIN of customer (Chakrabarti & Kardile, 2002, as cited in Sumanjeet, 2009). Smart cards are secure as they store information in encrypted format and are less expensive, provides faster processing. Mondex and Visa Cash cards are examples of smart cards.

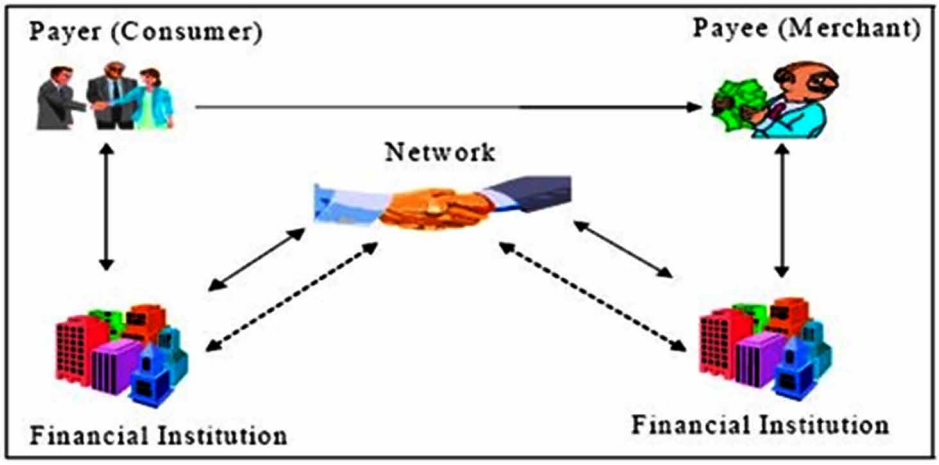
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5. Smart card

Online Cheque or Electronic Fund Transfer

Electronic Fund transfer is a transaction that happens among the accounts of same bank or different bank without the intervention of bank staff members which share a common computerized network. EFT's are also called as online transactions or PIN-Debit transaction. In EFT's there is a financial house called as Automated Clearing House (ACH) responsible for transferring the money from Payer consumer) to Payee (Merchant) account on the completion of transaction.

Figure 6. The figure depicts the usage of Electronic Fund Transfer [EFT]



Electronic Wallets (E-Wallets)

E-wallet applications may reside on mobile devices, computers or on Web servers at a service that manages digital wallet information. These apps can make online purchasing faster populating order forms

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

with billing, shipping and other information that you'd normally type manually. Some digital wallets may also store other important personal information, such as your driver's license and health care card data. If you lose a mobile device that has a digital wallet, people who find it won't be able to read its information because it's encrypted.

Electronic wallets being very useful for frequent online shoppers are commercially available for pocket, palm-sized, handheld, and desktop PCs as presented by the authors (Kaur & Pathak, 2015). They offer a secure, convenient, and portable tool for online shopping. They store personal and financial information such as credit cards, passwords, PINs, and much more. E-Wallets allow higher speed and much more efficiency for online shoppers.

Figure 7. The figure depicts the usages of E-wallet

METHODS OF ONLINE PAYMENT

Credit cards constitute a popular method of online payment but can be expensive for the merchant to accept because of transaction fees primarily. Debit cards constitute an excellent alternative with similar security but usually much cheaper charges. Besides card-based payments, other forms of payment have emerged and sometimes even claimed market leadership. Wallets like PayPal and Alipay are playing major roles in the ecosystem.

Net Banking

This is a system; well known that does not involve any sort of physical card. It is used by customers who have accounts enabled with Internet banking. Instead of entering card details on the purchaser's site, in this system the payment gateway allows one to specify which bank they wish to pay from. Then the user is redirected to the bank's website, where one can authenticate oneself and then approve the payment. Typically there will also be some form of two-factor authentication.

It is typically seen as being safer than using credit cards, with the result that nearly all merchant accounts in India offer it as an option.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

PayPal

PayPal is a global e-commerce business allowing payments and money transfers to be made through the Internet. Online money transfers serve as electronic alternatives to paying with traditional paper methods, such as cheques and money orders. It is subject to the US economic sanction list and other rules and interventions required by US laws or government. PayPal is an acquirer, a performing payment processing for online vendors, auction sites, and other commercial users, for which it charges a fee. It may also charge a fee for receiving money, proportional to the amount received. The fees depend on the currency used, the payment option used, the country of the sender, the country of the recipient, the amount sent and the recipient's account type.

Paymentwall

Paymentwall an e-commerce solutions providing company launched in 2010, offers a wide range of online payment methods that its clients can integrate on their website.

Google Wallet

Google Wallet was launched in 2011, serving a similar function as PayPal to facilitate payments and transfer money online. It also features a security that has not been cracked to date and the ability to send payments as attachments via email.

Mobile Money Wallets

In developing countries the banked population is very less, especially in tier II and tier III cities. Taking the example of India, there are more mobile phone users than there are people with active bank accounts. Telecom operators, in such geographies, have started offering mobile money wallets which allows adding funds easily through their existing mobile subscription number, by visiting physical recharge points close to their homes and offices and converting their cash into mobile wallet currency. This can be used for online transaction and E-Commerce purchases. Many payment options such as Airtel Money and M-Pesa in Kenya, ATW are being accepted as alternate payment options on various E-Commerce websites.

Comparison of E-Payment Systems

The table below shows the comparison of various E-payment systems such as Digital cash, credit cards, debit cards, smart cards, EFT, E-wallets against various features like users, transaction, efficiency etc., as presented by Sumanjeet (2009).

SECURITY MECHANISMS IN E-COMMERCE APPLICATIONS

E-commerce security is the protection of e-commerce assets from unauthorized access, use, alteration, or destruction. While security features do not guarantee a secure system, they are necessary to build a secure system. Online payment security protecting card details is the primary security risk with electronic

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

transactions. Customers are very comfortable using cards in shops and over the phone despite the ever-present risk of details being copied or stolen. With payments over the Internet, there is more resistance towards disclosing card information.

Table 1. Statistics of online shoppers as a percentage of Internet users in India

S. No	Feature	Digital Cash	Credit Cards	Debit Cards	Smart Cards	Electronic Fund Transfer	E-Wallets
1	Users	Any User	Any Credit Card Holders	Any user with a bank or credit card account	Any user with a bank or credit card account	Any User with a bank account	Any User with a bank account
2	Payment Time	Prepaid	Paid later	Prepaid	Prepaid	Direct Debit	Quick Payments
3	Transaction	Online	Online	Offline	Offline	Online	Online
4	Transfer Limit	Depends on Prepaid limit	Depends on limit of credit card	Depends on amount of money in account	Depends on amount of money Saved	Depend on account limits	Depends on Merchant
5	Mobility	No	Yes	Yes	Yes	Yes	Yes

Perception can get in the way of fact. Both software and hardware companies have invested a great deal to further protect online data and build up customer confidence. Be aware of the security issue and help customers to feel at ease by telling them about the precautions we have taken. In the current Internet climate it is vitally important that we are not only secure but are seen to be secure.

Security is an essential part of any transaction that takes place over the internet. Customer will lose his/her faith in e-business if its security is compromised (Tutorials Point, 2017).

Following are the essential requirements for safe e-payments/transactions:

- **Authentication:** Verifies who you say you are. It enforces that you are the only one allowed to logon to your Internet banking account.
- **Authorization:** Allows only you to manipulate your resources in specific ways. This prevents you from increasing the balance of your account or deleting a bill.
- **Encryption:** Deals with information hiding. It ensures you cannot spy on others during Internet banking transactions.
- **Auditing:** Keeps a record of operations. Merchants use auditing to prove that you bought specific merchandise.
- **Integrity:** prevention against unauthorized data modification.
- **Nonrepudiation:** prevention against any one party from reneging on an agreement after the fact.
- **Availability:** prevention against data delays.

Measures to Ensure Security

Major security measures are following:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Encryption:** It is a very effective and practical way to safeguard the data being transmitted over the network. Sender of the information encrypts the data using a secret code and specified receiver only can decrypt the data using the same or different secret code.
- **Digital Signature:** Digital signature ensures the authenticity of the information. A digital signature is an e-signature authentic authenticated through encryption and password.
- **Security Certificates:** Security certificate is unique digital id used to verify identity of an individual website or user.

Some of the best known options for the encryption and security of personal and card details are explained below. Almost every payment solution mentioned in this online payments tool includes this technology as standard. Online retailers will not need extra security measures if they use these market-tested and well-established products (Camenisch, Piveteau, Stadle, 1996).

Protocols for Securing E-Commerce Transaction

The security of E-Commerce transactions depends both on the network protocols and the payment framework used to perform the transaction.

Network Transport Security

Models such as Digi Cash, First Virtual, and Millicent provide a secure payment method. However, the transaction still depends on the privacy and authentication of the data stream. Basic TCP/IP networking protocols do not include encryption and strong authentication. Higher level protocols such as HTTP, FTP, and Telnet do little to provide advanced security measures beyond user id and password authentication. All information sent using these protocols is unencrypted, so the data stream lacks confidentiality.

Traditional networking protocols and applications are unable to enforce strong security measures for performing E-Commerce transactions securely. This lack of security led to the design and implementation of many new security protocols that strive to reach different security goals. There are some secure transport protocols that provide confidentiality and authentication between systems and applications by using encryption. The following section describes some of the more popular secure transport protocols.

Virtual Private Networking (VPN)

Virtual Private Networking technology provides the medium to use the public Internet backbone as an appropriate channel for private data communication. With encryption and encapsulation technology, a VPN essentially carves out a private passageway through the Internet. VPNs will allow remote offices, company road warriors, and even business partners or customers to use the Internet, rather than pricey private lines, to reach company networks. So the companies can save a lot of money.

Virtual private networks are flexible. They are point-to-multipoint connections, rather than point-to-point links. They can be set up or closed down at the network administrators will, making them ideal for short-term projects.

VPN has many advantages: It is much cheaper for connecting WANs than 800 numbers or dedicated T1 lines. It provides encryption and authentication services for a fairly good measure of privacy. Main-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

tenance of the WAN-to-WAN connection is left to Internet Service Providers. It is highly flexible, and can be set up and taken down very easily.

IPSec (Ipv6)

IPsec is a framework of open standards developed by the Internet Engineering Task Force (IETF). IPsec provides security for transmission of sensitive information over unprotected networks such as the Internet. IPSec acts at the network layer, protecting and authenticating IP packets between participating IPSec devices ("peers"), such as Cisco routers. IPsec provides the following network security services.

1. **Data Confidentiality:** The IPsec sender can encrypt packets before transmitting them across a Network.
2. **Data Integrity:** The IPSec receiver can authenticate packets sent by the IPSec sender to ensure that the data has not been altered during transmission.
3. **Data Origin Authentication:** The IPSec receiver can authenticate the source of the IPSec packets sent.
4. **Anti-Replay:** The IPSec receiver can detect and reject replayed packets.

Secure Socket Layer (SSL)

SSL is the Secure Sockets Layer protocol. Version 2.0 originated by Netscape Development Corporation, and version 3.0 was designed with public review and input from industry.

SSL (Secure Sockets Layer) is a communication system that ensures privacy when communicating with other SSL-enabled products. Technically speaking, SSL is a protocol that runs above TCP/IP and below HTTP or other top-level protocols. It is symmetric encryption nested within public-key encryption, authenticated through the use of certificates. An SSL connection can only occur between an SSL-enabled client and an SSL-enabled server. In fact, when a server is running in SSL mode, it can only communicate through SSL.

SSL allows traffic to be scrambled (or encrypted). The standard SSL developed by Netscape provides a high level of protection. It meets the following security requirements like:Authentication, Encryption, Integrity, and Non-reputability.

Secure Electronic Transaction (SET)

SET encrypts payment card transaction data and verifies that both parties in the transaction are genuine. SET, originally developed by Mastercard and Visa in collaboration with leading technology providers, has a large corporate backing and is perceived to be more secure as a result of its validation from card companies.

Private Communications Technology

SSL, created by Netscape, provides users with authentication of the server they are attaching to, encryption of the data sent and received, and integrity of the data being sent and received. PCT, created by Microsoft, provides protection against eavesdropping on a network or altering a network packet.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The Private Communications Technology (PCT) protocol furnishes the following elements of transmission security for client/server relationships over the Internet:

- Provides symmetric session-encryption keys between servers and clients.
- Accommodates authentication of server to client via Certificate of Authority (CA) trusted public keys; optionally, it also authenticates client to server.
- Verifies message integrity with hash function message digests, as explained earlier for the SET protocol.

Secure Hypertext Transfer Protocol (SHTTP)

SHTTP extends the HTTP internet protocol with public key encryption, authentication and digital signature over the internet. Secure HTTP supports multiple security mechanism providing security to end users. SHTTP works by negotiating encryption scheme types used between client and server.

CONCLUSION

Technology has inarguably made our lives easier. It has cut across distance, space and even time. One of the technological innovations in banking, finance and commerce is the Electronic Payments. E-Commerce or Electronics Commerce sites use electronic payment where electronic payment refers to paperless monetary transactions. Electronic Payments provides greater freedom to individuals in paying their taxes, licenses, fees, fines and purchases at unconventional locations and at whichever time of the day, 365 days of the year. Electronic payment has revolutionized the business processing by reducing paper work, transaction costs, labor cost. Being user friendly and less time consuming than manual processing, it helps business organization to expand its market expansion.

FUTURE RESEARCH DIRECTIONS

On the basis of present study, the first remark is that despite the existence of variety of e-commerce payment systems, credit cards are the most dominant payment system. Second, alternative e-commerce payment systems are some countries are debit cards. In fact, like many other studies, the present study also reveals that the smart card based e-commerce payment system is best and it is expected that in the future smart cards will eventually replace the other electronic payment systems. Third, given the limited users bases, e-cash is not a feasible payment option. Thus, there are number of factors which affect the usage of e-commerce payment systems. Among all these user base is most important. Added to this, success of e-commerce payment systems also depends on consumer preferences, ease of use, cost, industry agreement, authorization, security, authentication, non-refutability, accessibility and reliability and anonymity and public policy.

Chapter 45
Predictors of the Continued Adoption of WECHAT Mobile Payment

Isaac Kofi Mensah
https://orcid.org/0000-0003-2964-1736
School of Economics and Management, Jiangxi University of Science and Technology, Ganzhou, China

ABSTRACT

This research article integrates the technology acceptance model and diffusion of innovation theory to explore the factors predicting the continuance intention to use WECHAT mobile payment services in China. The results showed that perceived usefulness, perceived ease of use, perceived service quality, social influence, internet self-efficacy, relative advantage, compatibility, and complexity of were all significant predictor of the continued intention to use WECHAT mobile payment services. However, trust in the internet was not significant determinants of the continued intention to use. The results also demonstrated that internet self-efficacy is a predictor of perceived ease of use, relative advantage, compatibility and complexity of mobile payment services. Again, perceived ease of use and social influence were found to have a significant impact on the perceived service quality of WECHAT mobile payment. The implications of these findings on the adoption of mobile payments are discussed.

INTRODUCTION

E-commerce (EC) is defined as the use of the internet to exchange goods and services including information in a protected and secured manner (Kanchanopast, 2014). It is also the integration of business processes for business transactions to be conducted online through a computer network system (Kanchanopast, 2014). E-commerce also has the capacity to increase the efficiency, effectiveness, and performance of organizations (Ray, 2011). EC is also about the integration of business processes such as electronic fund transfer, supply chain management, online transaction processing, e-marketing, cooperate purchasing and value chain integrations (Thomas & Jose, 2015). Mobile payment is a kind of mobile transactions which

Copyright © 2021, IGI Global. Copying or distributing in print or electronic forms without written permission of IGI Global is prohibited.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

has to do with the payment transactions completed or enabled through a digital mobile technology via handsets with or without the use of mobile telecommunications networks (Diniz, Porto de Albuquerque, & Cernev, 2011). Mobile payment development and integration into the e-commerce platform have revolutionized the consumer engagement and completion of payments online through mobile payment apps. The mobile payment era has changed and provides a convenient environment for consumers to pay for goods and services without recourse to a banking card, visa/master card or any banking card payment system. Mobile payment has arisen due to the consumer desire to shop online through mobile handsets and tablets. This desire is premised on the availability of the internet and affordable smartphones which retail outlets are cashing on to provide better mobile shopping services to consumers and also as a better means to reaching the consumer faster (Yang & Forney, 2013). The mobile payment technology according to Diniz et al. (2011) has the capacity to deal with two very important issues on the demand and supply side of payment. The demand side offers a great chance for financial inclusion for persons are out of the catchment domains of traditional banking while the supply side creates opportunities for financial institutions to provide different services at low cost to the poorest sections of society (Diniz et al., 2011). The success of mobile payment technology in China is based on the massive technological investment in the development of electronic commerce in China.

The consumer's interaction with an EC technology will be incomplete without paying for the kind of good and services purchased online. The payment of goods and services has shifted from the desktop computers to notebooks and mobile or wireless systems of payment. In China, the mobile payment system has developed and spread so rapidly to the extent that is it has become a daily phenomenon. Mobile payment transactions in China reached RMB 294.97 trillion as at 2017 and it is expected to reach RMB 793 trillion in 2021. There are several mobile technology applications that are used by consumers to complete their transactions with vendors online in China. Statistics available indicate that as of February 2017, the majority of users of mobile payment services in China use Alipay and WeChat which represents 39% and 33% respectively of the mobile payment market in China. These mobile payment methods (Alipay AND WECHAT) are the two dominants mobile payment transactions in China. Other smaller mobile payment services are Apple Pay, Xiaomi Pay, and Huawei Pay which represents 5%, 2%, and 1% usage respectively in China.

The objective of this study is to investigate the factors influencing the continued adoption of the WECHAT mobile payment in China for payment of goods and services. The focus on WECHAT is because it is the most widely used mobile payment services in China. It has been opined that the consumer reluctance to uptake mobile payment services is due to the lack of adequate studies that critically examine the factors affecting the consumer acceptance and the factor discoursing its adoption (Bailey, Pentina, Mishra, & Ben Mimoun, 2017). Hence understanding the factors driving the continued adoption of WECHAT payment services can contribute to the designing and implementation of payment systems aimed at improving the efficiency and service quality of mobile payment services such as Apple Pay, PayPal, Alipay Wallet, and WeChat Wallet. Ultimately, these factors can largely ensure the users of mobile payment according to Zhou (2013) are empowered to use mobile access points such as smartphones to engage in payment of goods and services. Furthermore, understanding these factors can help companies to better appreciate and understand the consumer better and therefore can according to (Shin, 2010) increase the number of users of such payment systems. This study integrated the Technology Acceptance Model (TAM) and the Diffusion of Innovation Theory (DOI) to explore the predictors of the continuance intention to use WECHAT mobile payment. The integration of these two models is to provide a better contextual explanatory power for the adoption mobile payment services. The results

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of this integration on mobile payment adoption have contributed to enriching the e-commerce literature and by extension the mobile payment adoption literature. The research questions to be explored are: what factors predict the continued intention to use WECHAT mobile payment services and what is the significant impact of these predictors on the continuance intention to use?

The rest of this research paper is organized in the following manner: the research theoretical framework, research model and hypotheses development, results and data analysis, discussion and conclusion and limitation and future works are presented.

RESEARCH THEORETICAL FRAMEWORK

Technology Acceptance Model (TAM)

Perceived usefulness and perceived ease of use are the two major determinants of the user acceptance of new information technologies in the Technology Acceptance Model proposed by Davis (1989). The Technology Acceptance Model is considered the most widely applied theory to examine the intention to use a technology-related application in different fields and studies (Lai, 2017; Surendran, 2012). According to Davis (1989), Perceived usefulness is the extent to which a new user feels that the use of technology application will improve his or her job performance while the perceived ease of use is the user firm belief that in using any new technology-related applications it will be free from effort or challenges. These usefulness and ease of use of new technologies are crucial predictors of the actual use of technology (Davis, 1989). Recent studies have validated the direct impact of these two major determinants on the intention to use information system applications such as e-commerce/online shopping (Chen & Lan, 2018), e-government services (Mensah, Vera, & Mi, 2018; Susanto, Diani, & Hafidz, 2017), e-banking (Samar, Ghani, & Alnaser, 2017) and e-learning systems (Gamble, 2018).

TAM has been modified or combined with other models to examine the user acceptance of information systems. For instance, a model name the TAM-TPB model was developed to integrate TAM and the Theory of Planned Behavior and TAM2 which included new factors in the original TAM (Taylor & Todd, 1995; Venkatesh, Morris, Davis, & Davis, 2003). Trust was integrated with TAM to explore the user adoption of online shopping which explained some variance in the intended online behavior (Gefen, Karahanna, & Straub, 2003). This integration showed that online trust can be achieved through understanding that the vendor has nothing to gain by cheating, that are available adequate safety mechanisms in the website interface and also that the is easy to use (Gefen et al., 2003). Another study also integrated TAM with the TOE framework to expand the characteristic determinants for the adoption of e-commerce by SMEs (Awa, Ojiabo, & Emecheta, 2015). In a similar study, TAM was integrated with perceived risk to explain the customer acceptance of e-commerce which explains about 78.2% of the variance in the user's acceptance of e-commerce (ALraja & Aref, 2015). The results of this integrated model revealed that information misuse risk, failure to gain product benefits risk and functionality ineffective risk and perceived ease of use were significant determinants of the consumer acceptance of e-commerce (ALraja & Aref, 2015). Also, in the study by Zhao, Xue, Jin, Li, and He (2016), TAM was combined with TRA to study factors influencing the mobile e-commerce software adoption and use. Their study demonstrated that perceived usefulness, perceived ease of use, perceived security and perceived entertainment had both a direct and indirect impact on the consumer attitudes and intention to use while subject norms, as well as attitudes, had a direct effect on consumer intention to use (Zhao

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

et al., 2016). In examining the internet banking adoption issues in Pakistan, TAM was again integrated with customer service and customer satisfaction which revealed that perceived usefulness, perceive of ease of use, customer service and satisfaction are direct motivation factors for internet banking in that country (Ghani, Rahi, Yasin, & Alnaser, 2017).

Diffusion of Innovation (DOI) Theory

The Diffusion of Innovation (DOI) theory developed by Rogers (1995) to examine the way new technology-related applications are adopted within the population. Diffusion according to Rogers (1995, 2003), is the process through which a particular technological innovation is channeled or diffused in a frame of time among members of a social system. The diffusion of a particular technology can cover these areas: Firstly, characteristics of an innovation which may influence the adoption of such technologies. Secondly, the decision-making process when a person wants to adopt a new technology or product. Thirdly, the characteristics of a person can make them want to use an innovative technology. Fourthly, the consequences for the persons and society to use a new technology/innovation and lastly, the communication channels applied during the process of adoption (Rogers, 1995, 2003). According to Rogers (1995), there are four main factors that affect the diffusion of new technology innovation which are innovation itself, communication channels, time and a social system. Innovation has to do with an idea or practice that is considered new by users. The communication channel is a system which enables the user or consumers of new technology to share information with one another. The channel process is very important because the quicker or faster communication channel is, the quicker the process of diffusion of new technologies (Rogers, 1995). Time perspective in the diffusion process has to do with the time of uptake of the new innovation until the moment it stops to be in use. It takes notice of the pace with which an innovation is diffused into society and the extent to which it is used by a variety of users. Lastly, the social system is considered as an interrelated segment which is engaged in dealing with a problem to achieve a common goal (Rogers, 1995). All of these four elements are based on the crucial factor of human capital which implies that innovation should be adopted and used extensively in order for its sustainability (Rogers, 1995).

The extent to which an innovation is adopted can be as a result of five attributes such as relative advantage, compatibility, complexity, trialability, and observability (Rogers, 2003). Relative advantage is the user understanding that the use of an innovation-related technology would be advantageous to him or her. When innovation is considered by the user to be of greater benefits then it will lead to faster adoption rate. Complexity is the extent to which the user-perceives an innovation to be consistent with the values, past experiences and meeting the expectations of the user. Complexity is when innovation does not require new users to develop new skills and understandings towards using such technologies. Triability has to do with the extent to which new technology can be experimented on by users and lastly, observability is the potential of the user of new technology or innovation to see the outcome of such innovations. The Diffusion of Innovation has been applied and experimented on different technology applications to explain the extent to which such technologies will be adopted (Wu & Chiu, 2015; Zhu, Kraemer, & Xu, 2006).

RESEARCH MODEL

The research model to be investigated in this study is depicted in Figure 1. Perceived usefulness, perceived ease of use, perceived service quality, social influence, trust in the internet, internet self-efficacy, relative advantage, compatibility, and complexity are presumed to have a direct effect on the continuance intention to use WECHAT mobile payment services. Social influence and perceived ease of use are also expected to influence perceived service quality. In addition, internet self-efficacy is presumed to have a positive effect on the perceived ease of use, relative advantage, compatibility, and complexity.

Figure 1. Research model

RESEARCH HYPOTHESES DEVELOPMENT

Perceived Usefulness (PU)

The usefulness of new technologies has the potential to influence the extent to which individuals will be attracted to use such technologies. Perceived usefulness is considered one of the major determinants of the intention to use (Davis, 1989). According to Davis (1989), perceived usefulness is the extent to which the user is of the firm conviction that the use of a particular technology can improve his or her work performance. Hence it can be said that if the consumer perceives mobile payment apps to be usefulness they will then will be attracted to use such mobile payment app technologies. It has been demonstrated that perceived usefulness has a direct impact on the intention to use (José Liébana-Cabanillas,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sánchez-Fernández, & Muñoz-Leiva, 2014; Lee et al., 2017; Sánchez-Prieto, Olmos-Migueláñez, & García-Peñalvo, 2017). Consequently, H1 was proposed.

H1: Perceived usefulness has a positive influence on the continued intention to use WECHAT mobile payment.

Perceived Ease of Use (PEOU)

Perceived ease of use is also the main predictor of the intention to use in the Technology Acceptance Model (TAM) (Davis, 1989). It has to do with consumers understanding that the use of technology will be free of challenges or difficulties. If the use of new technology is considered by consumers to be of less effort, they will surely be drawn to use such technologies. Perceived ease of use has been validated to have a positive impact on the intention to use (Lee et al., 2017; Richard & Mandari, 2018). Also, the way a consumer perceives a technology to be free of challenges or less stressful to use can have a direct impact on the extent to which the service quality emanating from such technology will be perceived by the consumer. Hence, H2 and H3 were accordingly proposed.

H2: Perceived ease of use has a positive influence on the continued intention to use WECHAT mobile payment.
H3: Perceived ease of use has a positive influence on the perceived service quality of WECHAT mobile payment.

Perceived Service Quality (PSQ)

Service quality is considered as the consumer's anticipation of particular service and it is the difference between what the consumer expects and the actual service received (Grönroos, 1981; Parasuraman, Zeithaml, & Berry, 1985). It is also seen as the delivery of service of the excellent standard to meet the demand and expectation of consumers (Parasuraman et al., 1985). The extent of service received which matches the expectations of consumers have the capacity to influence the purchase intentions of would-be consumers positively or negatively. Studies have shown that service quality has positive impact on the decision of consumers to engage in repurchase and also the intention to use as well as the continuance intention (Chuang & Chiu, 2017; Gera, Mittal, Batra, & Prasad, 2017; Shi et al., 2018; M. Yang, Shao, Liu, & Liu, 2017). Consequently, H4 was proposed.

H4: Perceived service quality has a positive influence on the continued intention to use WECHAT mobile payment.

Social Influence (SI)

Social influence is considered as the extent to which a person's behavior, attitudes/actions or emotions change based on what others think or do and feel (Dolinski, Nawrat, & Rudak, 2001). Social influence in terms of comments, opinions, and emotions from relatives or persons of importance in society can affect the uptake or use of a particular related technology application such as mobile payment apps either positively or negatively. Not only do these comments or opinions affect the intention to use but

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

can also determine the service quality of such technologies. Social influence has been shown to have a direct impact on the willingness to purchase and intention to use (Almaimouni, Houghton, & Sandhu, 2014; Chin, Wafa, & Ooi, 2009; Razak, Bakar, & Abdullah, 2017). H5 and H6 were therefore proposed.

H5: Social influence has a positive influence on the continued intention to use WECHAT mobile payment.
H6: Social influence has a positive influence on the perceived service quality of WECHAT mobile payment.

Trust in the Internet (TI)

Trust is fundamental to human existence and interaction or engagement in any transactions. In this era of internet technology, a consumer's decision to trust is based on the assessment of risk which is explicit or implicit (Cerf, 2010). In situations where trust is low, it will be easier for the consumer to trust and if the risk is high, the consumer tendency to trust is expectantly low (Cerf, 2010). According to Quelch and Klein (1996), trust is an important element which can stimulate the decision of consumers to purchase over the internet technology. It has been demonstrated that trust in the internet has an impact on the willingness of consumers to patronize online stores and consumer purchase intention (Che, Cheung, & Thadani, 2017; Hallikainen & Laukkanen, 2018; Jarvenpaa, Tractinsky, & Vitale, 2000). Consequently, H7 was proposed.

H7: Trust in the internet has a positive influence on the continued intention to use WECHAT mobile payment.

Internet Self-Efficacy (ISE)

Internet self-efficacy is the consumer/ customer understandings or perceptions about their potential capabilities to use related internet technologies (Tsai, Chuang, Liang, & Tsai, 2011). It measures the confident levels of consumers' ability use and operates an internet application such as WECHAT mobile payment app (Purushothaman, 2017). The potential of would-be consumers to interact with and operate new Internet-related applications is definitely requires for the successful adoption of such technologies in terms of the consumer intention to use, relative advantage, perceive ease of use and the compatibility. Internet self-efficacy as shown by previous studies has an influence on the intention to use and perceived ease of use (Isaac, Abdullah, Ramayah, & Mutahar, 2017; Sharif & Raza, 2017). The following hypotheses (H8, H9, H10, H11, and H12) were therefore proposed.

H8: Internet self-efficacy has a positive influence on the continued intention to use WECHAT mobile payment.
H9: Internet self-efficacy has a positive influence on the perceived ease of use of WECHAT mobile payment.
H10: Internet self-efficacy has a positive influence on the relative advantage of WECHAT mobile payment.
H11: Internet self-efficacy has a positive influence on the compatibility of WECHAT mobile payment.
H12: Internet self-efficacy has a positive influence on the complexity of WECHAT mobile payment.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Relative Advantage (RA)

Relative advantage is of the major construct in the Diffusion of Innovation (DOI) Theory developed by Rogers (1995). Relative advantage has to do with the extent to which innovative technology is considered by users as superior/better as per the experiences of such users of that particular technology (Rogers, 1995). According to Rogers (1995), the greater the perceived relative advantage of a particular technology (innovation), the more likely such technologies will be adopted by would-be consumers. Since relative advantage is based on the perception and experiences with particular technological innovation, then it sounds it says that if they encounter good experiences then their understanding of such technology will be greater and vice visa which may have a positive or negative effect on the extent of adoption of such technologies. This can be related to the WECHAT mobile payment technology. Studies have shown that relative advantage has an effect on the intention to use (Carter & Campbell, 2011; Sin et al., 2016). H13 was hence proposed.

H13: Relative Advantage has a positive influence on the continued intention to use mobile payment.

Compatibility

Compatibility is also one of the variables in the Diffusion of Innovation (DOI) Theory propounded by Rogers (1995). Compatibility is considered as the extent to which a particular innovation technology is perceived or understanding of being consistent with the past experiences, values, and expectations of would-be consumers/adopters (Rogers, 1995). A new technology which the consumer considers incompatible with their beliefs, norms, values, and practices will be hard to adapt and hence will suffer diffusion challenges among the potential consumers but an innovation that is compatible will diffuse quickly (Rogers, 1995). This compatibility or incompatibility of new technology innovation can either have a positive or negative effect on the adoption and diffusion of new technologies like WECHAT mobile payment apps. Compatibility of innovation has been validated to have a direct effect on the intention to use (Carter & Bélanger, 2005). H14 was therefore proposed.

H14: Compatibility has a positive influence on the continued intention to use WECHAT mobile payment.

Complexity

Complexity is the extent to which a particular innovation is considered by users as difficult to comprehend and adopt (Rogers, 1995). Technology innovations that are easy to comprehend and understand will lead to faster adoption and diffusion as compared to innovations that are hard to comprehend (Rogers, 1995). In the EC platform, mobile payment systems which are less complex in terms of use to complete an online purchase will be adopted more as compare to apps that are complex. Hence, H15 was proposed.

H15: Complexity has a positive influence on the continued intention to use WECHAT mobile payment.

Research Methodology

The data for the conduct of this study was acquired through a self-administered questionnaire instrument to student population within the university community in Harbin Institute of Technology, China. The variable items were carefully selected after a thorough literature review was conducted. Perceived useless and perceived ease of use were adapted from (Alalwan, Dwivedi, Rana, & Williams, 2016; Davis, 1989; Moridis, Terzis, Economides, Karlovasitou, & Karabatakis, 2018; Venkatesh et al., 2003), perceived service quality, social influence and trust in the internet were adapted from (Jiang, Jun, & Yang, 2016; Nor & Pearson, 2015; Schnall, Higgins, Brown, Carballo-Dieguez, & Bakken, 2015; Sharma & Lijuan, 2015), internet self-efficacy, relative advantage, compatibility, and complexity were also adopted from (H. Akhter, 2014; Ozturk, Bilgihan, Nusair, & Okumus, 2016; Ramanathan, Ramanathan, & Karpuzcu, 2016; Sin et al., 2016). The questionnaire instrument was made up of two components. The first part was made up of demographic information about the respondents and the second part was about variables to be investigated in this study. The instruments were pretested and piloted to ensure that any misunderstanding that potential respondents may have in answering some of the questions were removed or reduced. The questionnaire was first prepared in English and translated into the Chinese Language for maximum comprehension of the expected respondents who are Chinese students. The questionnaire items used in this study is attached as Appendix 1. The items in the questionnaire were between using the Likert scale of measurement ranging from 1= Strongly Disagree (SD) to 5= Strongly Agree (SA). 20 undergraduate students were recruited to administer the research questionnaires which lasted for about a month between September and October 2017. The targeted population size was 1000 university students but after the administering of the instruments, only 896 of the instruments was duly returned which accounted for 89.6%. During the screening and checking of the returned questionnaire instruments, it was discovered that 102 of them were not fully completed and so they were discarded, leaving only 794 of instrument fully completed. The 794 instruments were found to be suitable (79.4), hence were captured and used for the data analysis. The Technology Acceptance Model (TAM) and Diffusion of Innovation theory were used as the theoretical framework for this study. The SPSS was used to capture and analyze the data.

RESULTS AND DATA ANALYSIS

Demographic Statistics

The demographic statistics of the respondents who participated in this study are shown in Table 1. The gender statistics of the respondents who took part in this study indicated that the majority were female (51.9%). Majority of the respondents were between the ages of 18-25 which represented 84.8%. Again, the majority of the respondents were undergraduates which account for 46.7%.

Average money spent a month shopping online

The average amount of money spent by the respondents to shop online is shown in Table 2. The majority of respondents spent between 100 to 500RMB per month on purchasing of items online (online shopping).

501-1000 RMB	213	26.8
1001+ RMB	174	21.9
Total	794	100

RELIABILITY ANALYSIS

The results of the reliability analysis conducted are shown in Table 3. Computation of the factor analysis was first conducted to determine the loadings of each question item. Question items whose loadings were below the values of 0.50 were not included in the computation of the Cronbach alpha. For instance, under the Compatibility variable, the item such as Campart_5 (0.425) was deleted because it has low values of 0.50. Also under the Complexity variable, the item Complex_5 (0.451) was also removed because of the same reason. The 48 items generated an alpha value of 0.827 which could be considered as good and acceptable Cronbach value and hence the data used for the analysis can be said to be reliable and consistent. The detailed analysis, as well as the computation of the factors and cronbach alpha, composite reliability, and average variance extracted, is shown in Table 3.

Correlation Analysis

The results of the correlation analysis conducted are shown in Table 4. It can be observed that perceived usefulness correlated positively and significant with perceived ease of use (PEOU) ($r = 0.351$, $p < 0.1$), perceived service quality (PSQ) ($r = 0.244$, $p < 0.01$), Social influence (SI) ($r = 0.093$, $p < 0.1$), internet self-efficacy (ISE) ($r = 0.135$, $p < 0.01$), Relative Advantage (RA) ($r = 0.152$. $p < 0.1$), Compatibility (CPT) ($r = 0.100$, $p < 0.1$), Complexity (CP) ($r = 0.114$, $p < 0.1$) and the continuous intention to use (CIU) ($r = 0.095$, $p < 0.1$). Furthermore perceived ease of use also correlated positively and significant

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

with PSQ ($r = 0.360$, $p < 0.01$), SI ($r = 0.191$, $p < 0.01$), TI ($r = 0.080$, $p < 0.01$), ISE ($r = 0.184$, $p < 0.01$), RA ($r = 0.166$, $p < 0.01$) and CIU ($r = 0.242$, $p < 0.01$). Also perceived service quality correlated positively and significantly with SI ($r = 0.377$, $p < 0.01$), TI ($r = 0.112$, $p < 0.01$), ISE ($r = 0.234$, $p < 0.01$), RA ($r = 0.291$, $p < 0.01$), CPT ($r = 0.115$, $p < 0.01$) and CIU ($r = 0.229$, $p < 0.01$).

** Correlation is significant at the 0.01 level (2-tailed)

* Correlation is significant at the 0.05 level (2-tailed)

In addition, social influence was positively correlated and significant with ISE ($r = 0.505$, $p < 0.01$), RA ($r = 0.330$, $p < 0.01$), CPT ($r = 0.179$, $p < 0.01$), CP ($r = 0.104$, $p < 0.01$) and CIU ($r = 0.114$, $p < 0.01$). Trust in the internet correlated negatively with CP but was significant ($r = -0.136$, $p < 0.01$).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

However Internet self-efficacy correlated positively and significant with RA ($r = 0.322$, $p < 0.01$), CPT ($r = 0.210$, $p < 0.01$), CP ($r = 0.135$, $p < 0.01$) and CIU ($r = 0.072$ $p < 0.05$). Again, RA correlated positively and significant with CPT ($r = 0.273$, $p < 0.01$), CP ($r = 0.084$, $p < 0.01$) and CIU ($r = 0.110$, $p < 0.01$). CPT also correlated positively and significant with CP ($r = 0.123$, $p < 0.01$) and CIU ($r = 0.094$, $p < 0.01$). Finally complexity correlated positively and significantly with CIU ($r = 0.118$, $p < .01$).

Testing of Research Hypotheses

A simple regression analysis was conducted to test the research hypothesis. The results of the research hypothesis tested are shown in Table 5. As shown in Table 5, perceived usefulness was significant in predicting the continuous intention to use WECHAT mobile payment ($\beta = 0.95$, $p < 0.05$). Hence H1 was supported and accepted. Perceived ease of use was also significant in determining both the continuous intention to use WECHAT payment app. ($\beta = 0.242$, $p < 0.05$) and the perceived service quality ($\beta = 360$, $p < 0.05$). H2 and H3 were also supported. Perceived service quality was also a significant predictor of the continuous intention to use WECHAT mobile payment. ($\beta = 0.229$, $p < 0.05$). H4 therefore supported. Social influence also found to be a significant determinant of both the continuous intention to use WECHAT mobile payment. ($\beta = 0.111$, $p < 0.05$) and the perceived service quality ($\beta = 0.377$, $p < 0.05$). Consequently, H5 and H6 were statistically supported and hence accepted. Trust in the internet was however not significant in predicting the continuous intention to use WECHAT mobile payments ($\beta = 0.31$, $p > 0.05$). H7 was hence not supported.

Table 5. Results of research hypotheses tested

Hypotheses	Path	r2	β	t	sig.	Supported
H1	PU→CIU	0.119	0.095	2.696	0.007	YES
H2	PEOU→CIU	0.159	0.242	7.021	0.000	YES
H3	PEOU→PSQ	0.230	0.360	10.859	0.000	YES
H4	PSQ→CIU	0.152	0.229	6.615	0.000	YES
H5	SI→CIU	0.113	0.114	3.225	0.001	YES
H6	SI→PSQ	0.245	0.377	11.460	0.000	YES
H7	TI→CIU	0.088	0.031	0.878	0.380	**NO**

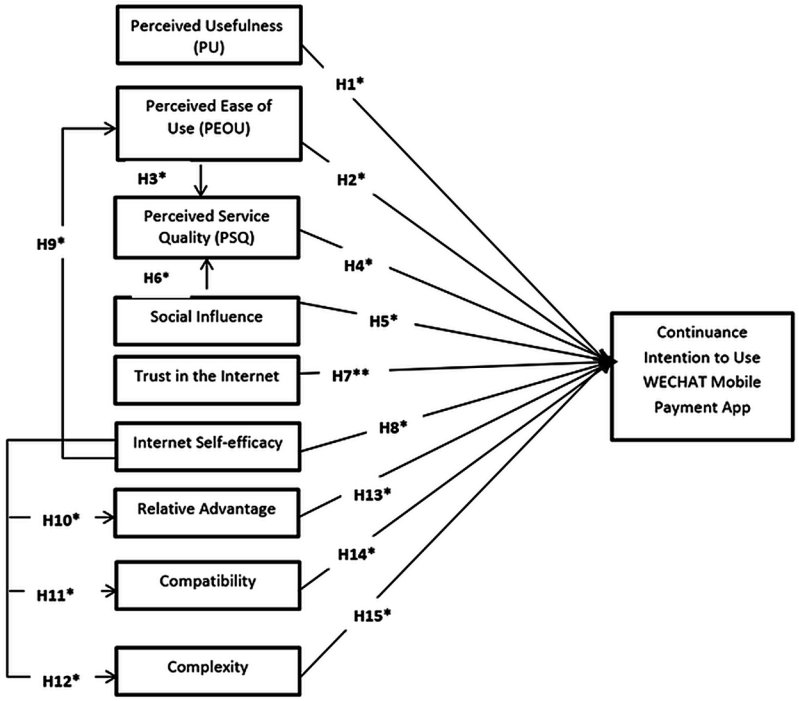
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, internet self-efficacy was significant in predicting the following variables: continuous intention to use WECHAT mobile payment ($\beta = 0.72$, $p < .05$), perceived ease of use ($\beta = 0.184$, $p < .05$), relative advantage ($\beta = 0.322$, $p < .05$), compatibility ($\beta = .210$, $p < .05$) and complexity ($\beta = 0.135$, $p < 0.05$). Hence, H8, H9, H10, H11 and H12 were all supported and accepted. Also, relative advantage was a significant determinant of the continuous intention to use WECHAT mobile payment. ($\beta = 0.110$, $p < 0.05$). H13 was therefore supported. Compatibility ($\beta = 0.094$, $p < 0.05$) and complexity ($\beta = .118$, $p < 0.05$) were both respectively significant predictor of the continuous intention to use WECHAT mobile payment. Consequently, H14 and H15 were supported and therefore accepted.

The significant path of the research model tested is shown in Figure 2.

Figure 2. Significance path model (. sig.; **. not sig.)*



DISCUSSION

China is the home to some of the largest internet users and active online shoppers in the world. This has provided a strong basis for the explosive development of the e-commerce market over the years. This Innovative technology as a result of this e-commerce boom has prompted the development of mobile payment technologies which enables the consumer to purchase goods and services without necessarily carrying hard cash. The mobile payment technology has consumed the daily life of the Chinese and has become the core aspect of the Chinese routine. This paper, therefore, explored the predictors of the continuance intention to use WECHAT mobile payment by Chinese users. The results demonstrated that perceived usefulness and perceived ease of use which is the core constructs in the TAM model were both

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

found to be a significant predictor of the continuance intention to use WECHAT mobile payment. This finding is consistent with studies that have shown that both perceived usefulness and perceived ease of use are positive determinants of the intention to use (Kim, Mirusmonov, & Lee, 2010; Shankar & Datta, 2018; Unnikrishnan & Jagannathan, 2017). The findings on PU and PEOU are inconsistent with studies which indicted the insignificant impact of these factors on the intention to use (Piriyakul et al., 2015). In addition, this study revealed that perceived ease of use was a positive predictor of the perceived service quality of mobile payment applications. Also perceived service quality was demonstrated to have a significant impact on the continuance intention of users to use WECHAT mobile payment. The significant impact of the perceived service quality on the continuance intention to use is in agreement with studies that have indicated that the quality of mobile payments applications increased both user experience and expectations which also positively affected the purchase intentions and intention use (Ramadan & Aita, 2018; Singh, Grover, & Kar, 2017).

Furthermore, the results indicated that social influence was positively significant determinates of both the continuance intention to use and the perceived service quality of WECHAT mobile payment. The findings on the social influence impact on the continuance intention to use are corroborated by other similar results which show that positive impact of social influence on the intention to use (Bhimasta & Suprapto, 2018; Chen, 2018). On the other hand, the positive impact social influence on the perceived service quality seems to be a unique addition to the literature since it has not been explored in other studies as far as the literature is concerned. Interestingly the results showed that trust in the internet was not a significant predictor of the continuance intention to use WECHAT mobile payment. This finding is a departure from and does not support studies which suggested that trust in the internet has a positive impact on the intention to use (Carter, Weerakkody, Phillips, & Dwivedi, 2016; Cho, Kwon, & Lee, 2007). However, internet self-efficacy was found to be significant determinants of both the continuance intention to use WECHAT mobile payment and perceived ease of use of mobile payment apps. The findings on the positive impact of internet self-efficacy are consistent with studies which demonstrated that internet self-efficacy has an influence on the intention to use (Al-Haderi, 2013; Ma & Liu, 2005), but however inconsistent with the findings which showed that it does not have an impact on the intention to use (Faqih, 2013). The result on the significant impact of internet self-efficacy on the perceived ease of use corroborates the studies which demonstrated that internet self-efficacy has a positive effect CT on the perceived ease of use (Isaac et al., 2017).

In addition, internet self-efficacy was shown to be positive predictors of relative advantage, compatibility, and complexity. The significant impact of internet self-efficacy on the relative advantage, compatibility, and complexity of mobile payment apps also appears to be the distinct contribution of this current study as far as the literature is concerned. Also, relative advantage, compatibility, and complexity were all determined to have a positive influence on the continuance intention to adopt WECHAT mobile payment. The findings on the positive impact of relative advantage on the continuance intention to use are consistent with studies that found the same effect of relative advantage on the intention to use (Arvidsson, 2014; Yunus, 2014). Again, the positive impact of the compatibility of mobile payment apps on the continuance intention to use is consistent and supports studies which showed the significant impact of compatibility on the intention to use (Al-Jabri & Sohail, 2012). The finding on this is also not in line with studies which have demonstrated otherwise, that compatibility does not impact on the intention to use (Yunus, 2014). Lastly, the finding on the significant impact of complexity on the continuance intention to use is not consistent with other findings which have suggested that complexity does not have an

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

effect on adoption (Al-Jabri & Sohail, 2012). But consistent with studies which have demonstrated that complexity has an effect on the intention to use (Choudrie, Alfalah, & Spencer, 2017).

CONCLUSION

This study integrated the Technology Acceptance Model and the Diffusion of Innovation Theory to explain the predictors of the continuance intention to use WECHAT mobile payment services from the Chinese users' perspective. The results have demonstrated that all the predictors of the continuation intention to use WECHAT mobile payment were statistically supported except in the context of trust in the internet which was found not be significant in determining the intention to use. Factors such as perceived usefulness, perceived ease of use, perceived service quality, social influence, internet self-efficacy, relative advantage, compatibility, and complexity were all positive determinants of the continuance intention to use WECHAT mobile payment. In addition, perceived ease of use of mobile payment apps and social influence were both significant predictors of perceived service quality. Also, it was revealed that internet self-efficacy had a positive impact on perceived ease of use, relative advantage, compatibility and complexity of WECHAT mobile payment.

These findings have implication for the continued adoption and use of mobile payment such as WECHAT payment which was the focus of this current study. These are some of the practical implications:

- Perceived ease of use and complexity of mobile payment apps in terms of its design should be given maximum attention by developers of these mobile payment apps since this study has shown that it has the potential to positively influence the consumer to use such apps.
- Again, users of mobile payment apps need to be convinced that use of mobile payment apps will be more useful towards enhancing his or her online shopping experience and that it is relative advantageous as compared to other forms of shopping such as from the physical store, since with this in mind it can drive users to continuously use mobile payment apps.
- The service quality of mobile payments such as WECHAT payment should be paramount interest to developers and vendors since the extent of quality service offered can have a positive effect or negative effect on the adoption of mobile payment. Timely feedback on a transaction payment which has gone bad and reliable attention to challenges consumers may have in using the mobile payment apps can impact on their decision to use mobile payment.
- In this global village where information spreads so fast due to the availability of social networks, the extent of recommendations from peers, friends, family and important elements of society (through social influence) either positive or negative arising from a user interaction with a mobile payment can affect the decision of new users as well as old users to use mobile payment services.
- The extent of internet self-efficacy of consumers and compatibility of mobile payment services to the daily routine of the consumer should be of great concern to mobile apps developers and vendors. This is because this study has demonstrated that both internet self-efficacy and compatibility are drivers of the continued intention to use mobile payment apps.

The results arising from the combination of the TAM and DOI has contributed to enriching the mobile payment literature with respect to WECHAT users in China. The specific contributions of this current study are: First, demonstrated the positive impact of perceived ease of use of mobile payment

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

apps on the perceived service quality of mobile payment services. Secondly, it provided empirical data supporting the significant impact of social influence on the perceived service quality of mobile payment services. Thirdly, demonstrated that internet self-efficacy has a direct effect on the relative advantage, compatibility, and complexity of mobile payment.

LIMITATION AND FUTURE RESEARCH

The first limitation is that no single study can fully explore all the factors determining the intention to use mobile payment services hence future studies will attempt to explore the impact of national culture on the adoption of mobile payment services. Secondly, the interpretation and generalization of the results of this current study should be done cautiously since the sample is just about 794 of students' population. Thirdly, the procedure and methodology applied in the study could be used in the context of another study but the findings may not necessarily reflect the findings of this study.

APPENDIX: RESEARCH QUESTIONNAIRE ITEMS

Perceived Usefulness (PU)

PU1: shopping and paying online through WECHAT is useful to me
PU2: Online shopping would make it easier for me to shop more quickly.
PU3: Using mobile WECHAT payment provides a better option for me to access services than the traditional means.
PU4: There is the timely delivery of goods and service after payment through WECHAT
PU5: Overall, I find the mobile payment (WECHAT) to be useful to access quality services from online retailers.

Perceived Ease of Use (PEU)

PEU1: It is easy for me to navigate through WECHAT mobile payment app website to shop and pay.
PEU2: It will take a short time for me to become skillful at shopping online.
PEU3: WECHAT mobile payment app and interfaces are easier to use
PEU4: It is easier to complete the payment processes on WECHAT mobile payment app
PEU 5: Overall, I find it easy to enter personal and payment WECHAT mobile payment app.

Perceived Service quality (PSQ)

PSQ1: service provided through WECHAT mobile payment is reliable and dependable
PSQ2: Access to WECHAT mobile payment service is fast and convenient.
PSQ3: Use of WECHAT mobile payment app is accurate and saves time
PSQ 4: Service accessed through WECHAT mobile payment apps portal/website meets my expectations of services required.
PSQ5: Overall, the service quality of service accessed through WECHAT mobile payment is good.

Social Influence (SI)

SI1: Family usage of WECHAT mobile payment app would also influence me to shop online.
SI2: Suggestions from my friends to use WEHCAT mobile payment apps would attract me to use it
SI3: A bad experience from my friends' use of WECHAT mobile payment app would discourage me from using it
SI4: If a person whose opinions that I value recommends WECHAT mobile payment app I will try it
SI5: Overall, suggestions from my friends and family would influence me to use WECHAT payment app.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Trust in the Internet (TI)

TI1: Data security for me is a concern to engage in WECHAT mobile payment
TI2: I am not comfortable to give my personal information on WECHAT mobile payment apps portals/ website while accessing public service
TI3: I trust WECHAT payment app website to protect my personal information while accessing e-government services.
TI4: I believe WECHAT mobile payment portal/website is trustworthy
TI5: Overall, I have high confidence that mobile payment website/portal is trustworthy

Internet Self-efficacy (ISE)

ISE1: I will need special IT/computer skills to enable me to shop and complete payment WECHAT
ISE5: I will be able to troubleshoot a problem when it occurs while using WECHAT mobile payment app.
ISE 3: I have many years of experience in using the internet.
ISE 4: It will be easy for me to get assistance/support if I need help shopping online using WECHAT payment app
ISE5: Overall, I think I have the right internet skills to shop and pay online through WECHAT payment app

Relative Advantage (RA)

RA-1 WECHAT mobile payment app a convenient way to shop and pay online
RA-2 WECHAT mobile payment app allows me to shop efficiently
RA-3 WECHAT mobile payment app prevents long queues
RA-4 WECHAT payment app is a complement to cash
RA-5 WECHAT payment app useful in managing my finances

Compatibility (C)

C-1 WECHAT payment apps fit well with my lifestyle to shop online
C-2 I like to try new technology
C-3 WECHAT mobile payment app fits into my working style
C-4 I like to adopt new mobile payment innovation
C-5 Overall, WECHAT mobile payment app is compatible with my lifestyle

Complexity (Com)

CO-1 WECHAT mobile payment app require lots of efforts
CO-2 WECHAT mobile payment app require good technical skills
CO-3 WECHAT mobile payment app can be frustrating at times
CO-4 WECHAT mobile payment app is easy to use
CO-5 WECHAT mobile payment app is not that complex to use

Continuance Intention to Use (CIU)

CIU1: I would use WECHAT mobile payment app for my different online transactions and access to all my shopping services needed.
CIU2: Using WECHAT mobile payment to access services while shopping online is nothing I would do
CIU3: I will continue recommend to others to use WECHAT mobile payment app
CIU4: I will use WECHAT mobile payment app as a tool to enjoy quality services through online shopping
CIU5: Overall, I will continue to use WECHAT mobile payment app services

Chapter 46
Enhancing Online Repurchase Intention via Application of Big Data Analytics in E-Commerce

ABSTRACT

Based on the empirical research, this chapter investigated the impact of big data-based techniques typically used in big-data driven E-commerce such as information search, recommendation system, dynamic pricing, and personalisation on the online repurchase intention in Malaysia. This study also investigated the mediating effect on customer satisfaction. Therefore this study utilised the quantitative research method with an explanatory study to predict the link between dependent and independent variables. Additionally, the snowball sample method was used to select a sample size of 318 working adults in Klang Valley. Next, a self-administered online questionnaire was used to collect the necessary data. The IB, SPSS 22 software was then used to assess the reliability and normality of the variables at the first stage. Next, the Confirmatory Factor Analysis and Structural Equation Modelling were examined via IBM SSS AMOS 22. The findings showed that the big data analytic factors like information search, recommendation system, dynamic pricing, and personalisation had a positive significant impact on customers' repurchase intention. Nonetheless, the mediation effect of customer satisfaction on information search, recommendation system, and dynamic pricing did not encourage the repurchase intention. Then, this chapter discussed the managerial implication, limitations, and future research scope. Finally, this study suggested strategies to enhance online repurchase intention via application of big-data analytics in E-commerce.

INTRODUCTION

In 2019, the global retail E-commerce sales amounted to US$ 3.53 trillion and the E-retail revenues are expected to further increase to US$ 6.54 trillion in 2022. Online shopping is one of the world's most common online operations however, the utilisation differs based on a specific area (Statista, 2019). In a joint study by Google-TNS (2018), Southeast Asia's internet economy is slated to worth more than US$240 billion by 2025, which is US$40 billion more than what was first projected in 2018. Additionally, by 2025, E-commerce is predicted to worth US$102 billion, which would make up more than 40 per cent of the total worth of the internet economy in the region. Malaysia is an attractive market for E-commerce in Southeast Asia because of its dynamic economy and developed infrastructure for digital technologies. Malaysia has ~ 25.84 million active internet users and the population has extremely high rates of mobile phone penetration. Malaysia has a total of 32.25 million people and 25 million of them are social media users, 40.24 million have mobile subscriptions, and 24 million of the population use social media on their mobile devices. Consumers spent an average of US$125 on online shopping in 2018 and the figure is expected to more than triple to US$390 in 2025 (Asian Post, 2019).

Although the E-commerce industry in Malaysia is relatively strong, it still faces obstacles to adopt the latest trends or tools in technology, lacks digital marketing skills, and lacks the market-access knowledge, and the regulations in cross-border E-commerce (Safie, Dastane, and Ma'arif, 2019). Besides that, Malaysian consumers still perceive various factors as risks in their online purchasing behaviour (Tham, Dastane, Johari, and Ismail, 2019). As E-commerce steps into a new competitive era, online shopping vendors need to stand out from others and present it well to become the market leader in the domain of online retail. Competition among these companies has become more aggressive, so it is imperative for businesses to identify the factors that enhance online consumer intention to repurchase (Hamza V. K, 2014).

Electronic marketing is a significant revolution in the era of globalisation (Bala M, 2018). Maximum business organisations have been running with technological change over the past decade. Big Data is a technology that enables large data sets to be unstructured and captured almost in real-time, and to be stored, processed, and combined in large quantities of different types of data from different sources (Brünink, 2016). Big data analytics methods are helpful for the large quantity of information that comes from heterogeneous sources of data such as textbooks, audio, video, social media, general data, and artificial intelligence (Villarejo R, 2019). According to (Chen, 2008; Haba and Dastane, 2018) it is still a challenge for companies to examine the factors that affect consumer repurchase intention in an online environment. Additionally, with the existence of the internet, online consumers have more access to data and a broad range of products and services As such, an information search is imperative for online shopping sites to provide reliable and accurate information (L. G. Pee, 2018). Furthermore, (Yan, 2018) found that the recommendation system provided consumers with the most suitable data and more pleasant shopping experiences. Besides that, (Alireza, 2019) identified a technique to personalise the features of online shopping according to the personality of the consumer, which may encourage repurchase intention. Therefore, it is highly significant to explore and completely comprehend the shift, which is presently taking place in the domain of internet shopping. Hence, a study should be conducted to examine Big Data analytics enables businesses to predict repurchase intention and enable them to concentrate on strategically focused online shopping activities, and (Merve, 2015; S.Vijayarani, 2016), improve customer satisfaction, and repurchase intention.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Numerous scholars had focussed on the connection between the mediating effects of customer satisfaction and the various factors and repurchase intention (Qureshi, 2009; Alshurideh, 2012; Quoc T P, 2018). Customer satisfaction is seen as a key differentiator in a competitive marketplace where businesses compete for customers. Therefore, customer satisfaction is the key element of business strategy. It is seen within the company as a key performance indicator (Christopher, 2014; Dewa, 2018; Asyraf, 2019). Extensive studies had shown that online shopping is influenced by buying intentions (Chao, 2011; Fatemeh, 2016; Pasharibu, 2018). Therefore, when behaviour is repeated and becomes habitual, an automated cognitive process is considered in which a habit is exercised (Khare, 2005). Some scholars said that a weak online shopping habit results from the apprehensions that consumers have when doing business on the web, especially with unfamiliar merchants (Anderson, 2003). Therefore, the customers' online shopping habits and repurchase intentions improved when the merchants and dealers had successfully satisfied their customers. However, the mediating effect of customer satisfaction is yet to be explored based on the big data analytic factors and repurchase intention.

Studies had investigated the impact of big data analytics on the factors of consumer behaviour (see. Le and Liaw, 2017; Lo and Harvey, 2012). Nevertheless, zero studies were done on the impact of big data analytics on customer repurchase intention mediated by customer satisfaction in Malaysia. Therefore, the current study will fill the existing vacuum of understanding of the subject matter. Hence, this study determined the effect of big data analytics on the online consumer repurchase intention in Malaysia. Furthermore, the present research also examined the mediating effect of customer satisfaction based on big data analytic factors such as information search, recommendation system, dynamic pricing, and personalisation and repurchase intention on online shopping. The subsequent objectives are considered crucial in the context of the Malaysian E-commerce industry: (a) to inspect the impact of information search on repurchase intention, (b) to inspect the impact of recommendation system on repurchase intention, (c) to investigate the impact of dynamic pricing on repurchase intention, (d) to inspect the impact dynamic pricing on repurchase intention, (e) to examine the impact of personalisation on repurchase intention, and (f) to inspect the impact of mediating effect of customer satisfaction based on the big data analytic factors and repurchase intention. Hence, this research identified and critically evaluated the impact of information search; recommendation system, dynamic pricing, and personalisation as part and parcel of the independent variables to study their impact on the online repurchase intention mediated by customer satisfaction.

LITERATURE REVIEW

Review of Key Literature

Big Data Analytics

The term big data refers to information that cannot be processed or analysed using traditional tools or processes. (Chris et al., 2012). Hapler and Krishnan (2013) stated that many organisations have started using big data solutions because they deal with specific business problems that require big data to be solved. Besides that, the data economy also produces a wide and constant stream of data that is monitored and analysed using advanced technologies and techniques to provide new insights that are necessary for better decision-making and improved business performance. (Luen, 2015) Therefore, big-data plays an

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

important role in online repurchase intention. (Pavithra B, 2016). Big data is a dataset capable of being captured, communicated, aggregated, stored, and analysed (Thi and Shu, 2017). Additionally, big data increases its velocity by exceeding the old computing methods. It analyses the involved data volumes and mines information, and calculations n big computational amounts. (Muhammad, 2018).

Big Data Analytics (BDA) refers to "quantitative fact-based' analysis, which aids the process of decision-making (Davenport, 2006). BDA generates value via transparency, discovery, variability exposure, and performance improvement (Manyika, 2011). E-commerce companies are one of the BDA adopters 'fastest groups because they need to remain on top of their game (Koirala, 2012). Big data analytics is where advanced analytical techniques are applied to big data sets. Therefore, based on the large data samples, analytics reveal and leverage changes in business (Nada, 2014) Multiple studies had found a sufficient knowledge of customer service via the Big Data Analytics methods and systems to better help the needs and expectations of the customers. Besides that, decision support plays an important role in the management of customer relations. Therefore, predictive analytics will help manage relationships in the business environment in the future. Many tools are used with big data technologies that provide better standards of customer-relationship management skills. Big data analytics help deliver faster value to the customer (Romika, 2015; Tomas, 2017; Li Q. C., 2017). (Akter, 2016) categorised BDA'S business value as E-commerce companies' transactional, informational and strategic benefits. As a result, Big data analytics help companies generate consumer-centered insights to improve business operations (Avinash B.M., 2017). Big data analytics enables companies to quickly access and analyse multiple data sources, improve decision-making, develop tailor-made services that meet consumer needs, and better assess lending activities to minimise losses (Jiwat, 2017).

Information Search

The internet has become a powerful tool for information search and E-commerce (March L, 2001). Consumers frequently choose their brands and products via the internet The internet gives customers the authority to search for significant information and buy their desired products (Moon, 2004). Moon (2004) further stated that online shopping is, therefore, highly effective in comparison to traditional marketing channels. Besides that, customers can also search for information and seek appropriate options for their product selection (Fiona, 2005). Therefore, information-search is the first phase of the customer purchase process. Hence, Adeline (2006) asserted that information-search is a significant state because potential customers receive advertising messages that may influence their choices and decision-making abilities. (Farhang, 2012) said that data-search is a process, which assists clients to make choices in the online shopping platform. Data-search is an excellent tool to help online shoppers discover the appropriate products or the necessary services Therefore, it is crucial for potential customers to be able to browse for information before decision-making. As such the online retailers need to enhance data support and offer a comprehensive list of product data and use the inner search engines to enhance the efficacy of data-search (Mittal, 2013). Evidently, E-commerce increases the availability of information exponentially, provides customers access to product-service knowledge, possesses a better quality, and is faster than before (Fawzy, 2018).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Personalisation

Personalisation focuses on fulfilling a special requirement. It can be directed towards people (customers or employees) as well as the organisational roles in companies such as purchasing agents (Petra, 2004). Christoph (2010) claimed that there is a close relationship between personalisation and the recommended items by the online portal. Moreover, (Narongsak, 2011) defined website personalisation as any action that adapts the information or services provided by a website to the needs of a particular user or a set of users. Researchers view customer personalisation as segments of the market with notable differences. For example, market segmentation is not based on the needs identified for online applications. According to (Allyson, 2013; Radu, 2015; Agarwal, 2015) web personalisation generates tailor-made website information and presentation layouts by identifying the user's implicit or explicit needs. The industry has implemented multiple customised systems such as Amazon's recommender systems, eBay and other E-commerce websites, or gmail.com and outlook's customization tools, in practice (Darshana, 2016). Personalisation defines the numerous differences among individuals. Various characteristics of personalisation and styles of decision-making communicate with an online store (Alireza, 2019).

Recommendation System

The recommendation system is an important area of application (Timothy, 2002). (Chi, 2011) had established a personalised E-commerce recommendation system model based on multi-agent technology and introduced the principle, and algorithm of the key agent to the model. Web-based recommendation systems are convenient for users because users do not need to provide user rating data explicitly in comparison to the traditional collaborative filtering technique (Yang, 2012). A recommendation scheme is a technique used in E-commerce that can collect products and create suggestions for clients. It can enhance the capacity to sell websites for E-commerce, transform tourists to clients, and boost customer loyalty (Chen, 2014). An online recommendation system involves using information technology and customer information to tailor Ee-commerce interactions between a business and an individual customer (Seth, 2015). The recommendation system guesses the shopping preferences of the customer according to the features of the products the customer bought in the past and then recommends comparable products to him or her. Furthermore, (Ankush, 2017) suggests that 'personalised recommendation is generally applied to online shopping websites to provide recommendations to their users. The recommendation system uses collaborative filtering techniques that have been successful in providing recommendations. Recommendation systems usually include cooperative content-based filtering and other methods for data mining, such as decision trees, association rules, and semantic methods (Yan, 2018).

Dynamic Pricing

Dynamic pricing is the free adjustment of the price of the products based on the supply and demand, even at the individual level of the transaction (Wim, 2014). Dynamic pricing adjusts the prices of identical goods online to match customers' willingness to pay (Robert M., 2001). The increased capacity of online retailers to learn about their customers ' shopping behaviour has risen concerns of dynamic pricing, a practice where a vendor sets prices based on the readiness of the buyer to pay (Oliver, 2011) . Therefore, when there is a change in demand or in other parameters, dynamic pricing, which is merely a price change, could be helpful to determine the suitable price. Besides that, dynamic pricing comprises

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of measurable demand, client sensitivity, and other factors (Başak, 2013). According to (Rainer, 2016) dynamic pricing strategy maximises expected long-term discounted profits. Every seller wants to set the selling price of their products to increase their revenue (Anusha, 2017). Strategic consumers expect that a future discount may find a current purchase less attractive in response to dynamic pricing. As a result, a dynamic pricing strategy that ignores strategic customer behaviour can prove to be suboptimal (Chaitanya, 2018).

Customer Satisfaction

According to (Kotler and Keller, 2009) customer satisfaction is the outcome of experiences during different buying phases: a need for something, collecting data about it, assessing buying options, making real buying choices and post-purchasing behaviour. Similarly, (Syed, 2010) defined customer satisfaction as the ultimate result of meeting the expectations of a consumer based on product and service performance. Moreover, customer satisfaction is one of the crucial factors in the research of consumer behaviour in both traditional and online business environments. Customer satisfaction is generally viewed in different behavioural contexts because of the comparison between consumer expectations and experience and therefore, customer satisfaction is achieved when the final delivery meets or exceeds the expectations of the customer (Izyan, 2014). In their study, (Sathiya, 2016) found that online shoppers' satisfaction was related to their recent purchase area of residence, age, gender, occupancy, and cost. Furthermore, in an online environment, customer satisfaction is one of the key factors leading to increased customer retention and the long-term growth of online stores (Urvashi, 2017). Most customers are very satisfied with the price of the product, followed by the discount offered, and the time taken for the product to be purchased online (V. Mathan and R. Velmurugan, 2017; Nebojša, 2019) .

Repurchase Intention

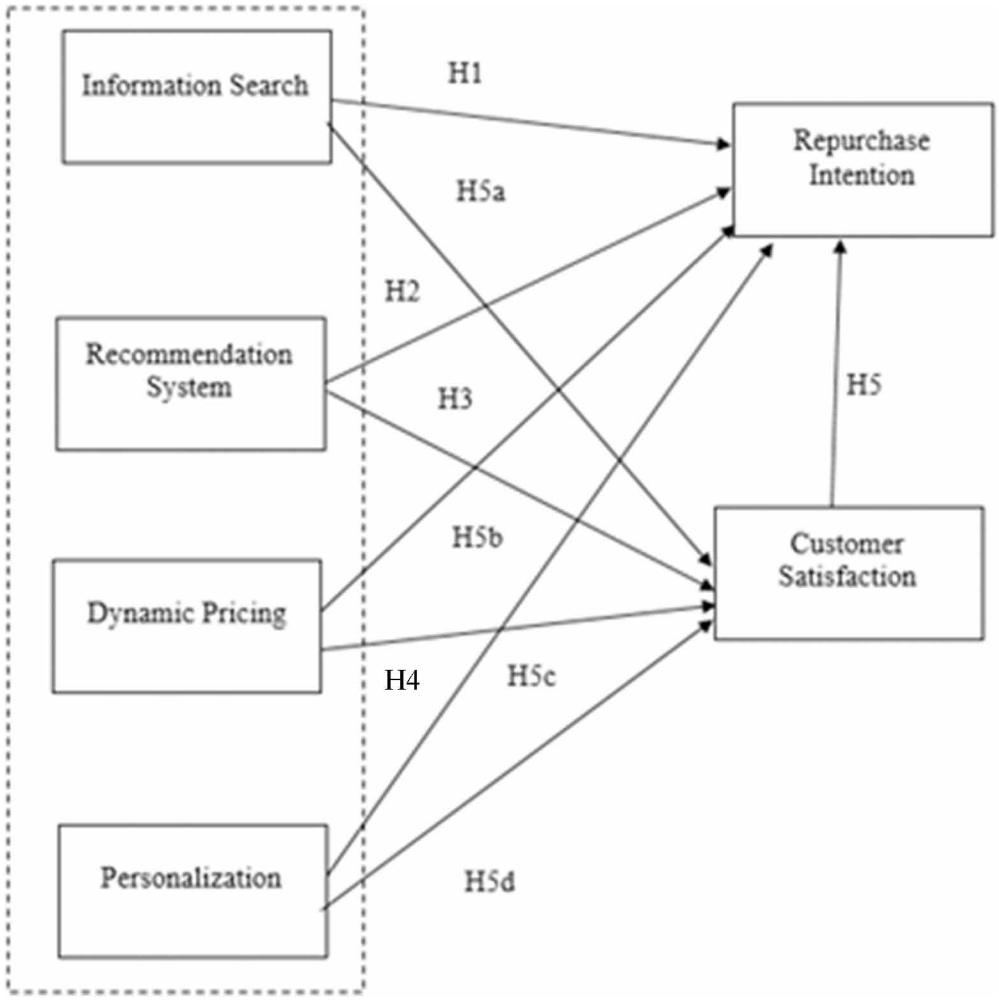
Repurchase intention can be defined as the willingness of an individual to make another purchase from the same company based on his/her past experiences (Hellier, 2003). (Lin, 2014) stated that repurchase intention is when a repeated behaviour becomes habitual as a result of the automated cognitive process. Customers with distinctive personalities may react differently to similar benefits, therefore, resulting in the differences in their perceived value, which may ultimately exhibit different repurchase intentions (Fang, 2016). Moreover, (Jobo, 2016) claimed that repurchase intention involves the general experience of the clients to-date, their satisfaction with the products or services, and the ability to retain the customers' satisfaction to encourage their intention to buyback.

Moreover, (Sahe, 2016) defined repurchase intention as repurchasing the purchase from a specific vendor via the online stores. Additionally, online shopping platforms face more difficulties in comparison to an off-line context because of the absence of face-to-face interactions with the distributors, unreliable internet configuration data, distrust, low switching costs, uncertainty, and spreads fast via word-of-mouth. (Donni, Dastane, Haba and Selvaraj, 2018). Nevertheless, the intention to buy off-line cannot completely embody the spirit of internet shopping (Chou, 2016). The innovation of consumer service and product quality will affect the repurchase intention (Yang, 2017). Furthermore, (Quoc T P, 2018) revealed that the intention to purchase back is one of the most significant marketing behavioural objectives that ensure customers are prepared to purchase at the same online store or seller again.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Correspondingly, (Xin K L, 2018) also highlighted that boosting the customers' repurchase intention is the key strategy to generate higher profits for the online vendor. Many previous studies reported the impact of Big Data analytics to business values and business challenges (Akter, 2016; Barton and Court, 2012). However, insufficient research had been done on customers' views to examine how customers react to the application of Big Data Analytics on the online repurchase intention. Thus, the research on customers' online repurchase intention based on the application of Big Data analytics is becoming an advanced trend in the marketing strategy (Le and Liaw, 2017). Additionally, the mediation effect of customer satisfaction based on the Big Data Analytics factors and repurchase intention was limitedly researched too.

Figure 1. Conceptual Framework



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Conceptual Framework and Hypotheses Development

A study by Prudon (2015) showed that the variables such as the comfort of access, the convenience of search, the convenience of assessment, the comfort of the transaction, and comfort of ownership / post-purchase were significant variables that contributed to the customer's perceived value and intention of repurchase. However, (Maria, 2012) stated that the effect on online website design and product variation satisfaction was not significant but it had a direct impact on e-shoppers' loyalty. Data privacy and data security are an inevitable issue in the Big Data age (Kalina, 2017). Moreover, (L. G. Pee, 2018) indicated that the moderating effects showed that website usability signalised that information remained significant even for low-risk shopping customers and for experienced online shoppers. (Quoc T P, 2018) revealed that data search was more convenient with a user-friendly interface website, which intended to assist clients to move readily, incorporate search instruments, and compare products to assist clients to discover the product that best suits their requirements. This was significant to contribute to the factors that boost clients' desire to repurchase (Haba and Dastane, 2019). The proposed framework contains four key factors of big data analytics and the combination of these four are unique and contributed to the field of literature.

H1: There is a positive and significant impact of information search on repurchase intention.

The recommended online shopping system focuses on electronic retail-specific characteristics and requirements. This research used a hybrid model, which supported the dynamic recommendations, eliminated the problems that the underlying techniques had when they were used alone (Prassas, 2001). (Jiang, 2010) and (Chen, 2012) stated that comments and recommendations affected clients' online shopping experience, online shopping satisfaction, and their intention to shop online. Nevertheless, Shahab (2012) found that there was a need to put in extra effort to overcome the shortcomings of the existing techniques of the recommendation system. According to (Thi and Shu, 2017) the recommendation system enabled consumers to readily identify and match their preferences and interests, and therefore it improved customers' desires and behaviour. Furthermore, from the client's perspective, customers want to be more satisfied with the recommendation system to enhance their purchase and decision making so that the products fulfil their own preferences. Therefore, Poonam (2018) conducted research on the moderating effects of product attributes and consumer reviews on the effectiveness of the e-commerce site's collaborative filtering recommendation system. Besides that, it impacted the sales volume and the diversity of several different recommend algorithms, commonly used in e-commerce and online services. Therefore, complete and precise information must be given to ensure customers can assess the product correctly. This helps ease the assessment. It is also necessary to provide the capacity to sort and compare products between distinct stalls by cost. Social media is increasingly influencing daily purchasing choices (Vahid, 2018).

H2: There is a positive and significant impact of the recommendation system on repurchase intention

Dynamic pricing involves using historical data such as previous purchases, clickstream, cookies, business resource planning systems to set an item's prices dynamically or offer customised discounts (Uyoyo, 2014; Anusha, 2017). Although the evolving internet-based technologies provide e-commerce companies with transformative advantages (e.g. real-time client service, dynamic pricing, tailored offers

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

or improved interaction), BDA can further enhance these effects by allowing informed choices based on critical ideas (Akter, 2016). Moreover, (Avinash B.M., 2017) examined major Big Data applications: customisation, dynamic pricing, customer service, customer behaviour prediction, visibility of the supply chain, and fraud management. Furthermore, (Thi and Shu, 2017; Vijay, 2018) revealed that dynamic pricing had significantly improved customer service to greatly satisfy the customers. However, the recommendation system was the most influential factor, followed by information search, and finally dynamic pricing. Furthermore, (Lily, 2017) stated that price perception did not influence customer satisfaction however, it influenced the customer repurchase intention as a result of the satisfaction with the e-service quality. According to (Aypar, 2018) examined price sensitivity on the intention to repurchase based on the customers' personalities and characteristics. Therefore Aypar (2018) investigated the extent to which personality or characteristics affect price sensitivity.

H3: There is a positive and significant impact of dynamic pricing on repurchase intention.

There are three significant factors that affect the comfort of website data: website type and data range, website design and website attractiveness, and personalisation of the website. Website personalisation enables companies to attract more clients to their website. This sort of client appeal is one of the most efficient marketing techniques of a company (Farhang, 2012). The online sales profiling essential offers user information and purchase choices, that help the marketing team to concentrate on client needs, products, services, and expectations. Therefore if a visitor matches a profile, a custom content personalisation will be provided. This offers an extremely appropriate, engaging, and improved user experience leading to a substantial rise in conversion and income levels (Radu, 2015). However, (Christoph, 2010) revealed that the set of articles collected was not sufficiently large to assume a constant interest in the area of personalisation. Hence, Big data analytics enables personalisation- based service or products to be provided to customers (Avinash B.M., 2017). This personalisation can streamline the decision-making process and boost satisfaction. This research introduced a technique to customise the characteristics of an online store according to the users ' personalities. These equations are then used to customise the features of the shops to improve customer satisfaction and convince them to make bigger purchases (Jaewon, 2017).

H4: There is a positive and significant impact of personalisation on repurchase intention.

(Mohsan, 2011) found that customer satisfaction was positively correlated to the repurchase intention and was adversely correlated to the customers' plans to switch. (Fadilah, 2017; Xin K L, 2018) revealed that confirmation was the most powerful determinant, which enhanced the customers' intention to repurchase via online shopping sites. Therefore, online retailers should be informative and should provide valuable information at the same time, as this can reduce information search time. Additionally, the information provided must match the customers' needs to increase the effectiveness of the information. Online retailers should provide up-to-date, accurate, useful, and comprehensive information on their websites to ensure that the needs of customers are met and therefore, satisfied (Julianti, 2014; Izyan, 2014). Furthermore, the perceived expectation of performance and satisfaction also had a significant impact on the online shopping experience and on the repurchase intention in Malaysia. As more Malaysians are exposed to e-commerce, it is expected that e-commerce players will take advantage of the evaluation report and improve their websites to provide consumers with the level of satisfaction that guarantees repeated visits, and therefore, increase revenue (Fawzy, 2018). However, (Lily, 2017) examined the impact of e-service

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

quality and experiential marketing via client satisfaction since the mediation variable had no impact on the intention to purchase back. Moreover, (V. Mathan, 2017) conducted a study to identify the level of customer satisfaction pertaining to online shopping to identify the factors that encourage their satisfaction. Therefore, the empirical evaluation of the obtained equations showed that the proposed method of personalisation improved customer satisfaction (Darshana, 2016; Muhammad, 2018; Alireza, 2019). The outcomes of the study showed that customer satisfaction was associated with marital status and the number of problems faced by the. Furthermore, (Quoc T P, 2018; Alif, 2018) the outcomes also indicated that the performance expectancy affected online shopping customer satisfaction. On the other hand, cost savings, perceived ease of use, the security of service, and expected performance influenced customer repurchase intention.

H5: There is a positive and significant impact of customer satisfaction on the repurchase intention.
H5a: Customer satisfaction mediates the relationship between information search and repurchase intention.
H5b: Customer satisfaction mediates the relationship between recommendation system and repurchase intention.
H5c: Customer satisfaction mediates the relationship between dynamic pricing and repurchase intention.
H5d: Customer satisfaction mediates the relationship between personalisation and repurchase intention.

RESEARCH METHODOLOGY

This research was carried out based on the positivist and deductive approach in the epistemological position. Additionally, an explanatory design was applied to predict the connection between the dependent variables (Repurchase Intention and Customer Satisfaction) and the independent variables (Information Search, Recommendation System, Dynamic Pricing & Personalization) via the process of hypothesis testing. Besides that, a qualitative method was also implemented with a structured survey questionnaire.

According to (TheEDGEmarkets, 2018) Malaysia has 15.3 million web shoppers (50% of Malaysia's population). This was irrationally huge sample size for research because 10% of the total population in which a sample size of 15,300 was too big and too expensive, required a lot of effort, and was time-consuming to be examined. Therefore, the present study embraced Bartlett's (2001) formula where the rule of thumb is t-value=1.96 and alpha level=0.5 for more than 150 sample sizes when the lower target of populations is involved. Therefore, the targeted group of population in this study was made up of Malaysian internet shoppers who were 18 years and above (Stated by Direct Sales Act 1993 as the legal age to join) regardless of their gender and race. Finally, this study obtained a total of 318 questionnaires that were suitable as a sampling population. Next, a self-administered, structured questionnaire was used online to collect the necessary data. The snowball sampling method was used to obtain the appropriate information from the present internet users in Klang Valley to avoid financial constraints and ensure time-efficiency Additionally, this study used the Google survey form via electronic delivery and the survey information was stored. This was a convenient method since the questionnaire was easily accessible online and in real-time. This was convenient for the respondents of this study. Participants needed to completely comprehend the objectives of the present study while the study was conducted with strict confidentiality. The survey questions were develop based on the previous research carried out by other researchers.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

A set of identical issues with close-ended questions and scale-response questions were given to the participants. Next, the questionnaire was divided into two segments. Section A examined the private and background data linked to the online shopping sector of the participants. This section included participants' demographic information such as race, age, gender, education, earnings, marital status, frequency of online shopping, and favourite website. Section B focused on participants' views based on the factors of online shopping recognised in Malaysia. This study adopted the Rating scale questions, which allowed the respondents to assess online shopping issues based on the provided variable, which was flexible to develop the questionnaire. The issues in the study were based on six factors such as information search (IS), dynamic pricing (DP), recommendation system (RS), personalisation (P), customer satisfaction (CS), and repurchase intention (RI). The questionnaire instruments used in this study were based on the 7-point Likert scale, which ranged from *Very Strongly Agree* to *Very Strongly Disagree*, followed by *Neither Agree nor Disagree* in between to determine the attitude of the respondents with regards to the current subject matter. (Creswell, 2014).

The rule-of-five sample selection method (36 items multiply with 5) was adopted for the sample size in this study, which consisted of at least 180 samples that were suitable as a sample population (HT Chong, 2014). Additionally, the questionnaires were doubly distributed to the various internet shoppers in Klang Valley. Finally, a total of 318 questionnaires were obtained and were used in this study as a suitable sampling population Post-data collection, different methods of statistical data analysis that were consumed to identify the connection between variables via the Social Science Statistical Package (SPSS). In this study, the data analysis scheme included descriptive analysis and accuracy analysis statistics, analysing normality, testing reliability, and validity using SPSS software 22. The confirmatory factor analysis (CFA) and variance assessments were acquired in the subsequent phase. To identify the general suitability of the assessment model, the Structural Equation Model (SEM) was created using AMOS 22 to evaluate internal consistency.

RESULTS AND DISCUSSION

Demographic Analysis

The present study had distributed a total of 350 questionnaires to a group of working adults in Malaysia. Based on the given questionnaires about 91% (318 out of 350) of the data was obtained successfully. Out of the 318 respondents, 58.5% were males and 41.5% were females. This revealed a gender balance in the present research. About 38.7% of the respondents aged between 31 and 40. Additionally, the majority of online shoppers were Chinese (72%). About 80.2% of the respondents visited online shopping platforms and purchased products or services monthly. Besides that, 69.2% of the respondents who had online shopping experience were married and 37.1% of them were married with kids. Based on the obtained questionnaires, the respondents from two major groups of monthly income favoured online shopping. For example, 31.8% of the respondents have a monthly cash income of RM5,001-10,000 whereas 30.5% of them have a monthly cash income of RM10,000. These groups of people have the financial freedom to spend shopping online. Next, 80.2% of the respondents shop online monthly About 40.9% of the respondents chose *Lazada* as their number one online shopping platform whereas 33.6% favoured *Shoppe.* These platforms match with the i-price top 10 online shopping sites in Malaysia (iprice, 2019).

Table 1. Reliability Analysis

Variable	No. of Items	Cronbach's Alpha	Assessment
Overall	30	.929	Excellent
Information Search (IS)	5	.966	Excellent
Recommendation System (RS)	5	.911	Excellent
Dynamic Pricing (DP)	5	.908	Excellent
Personalization (P)	5	.876	Good
Customer Satisfaction (CS)	5	.886	Good
Repurchase Intention (RI)	5	.907	Excellent

Reliability Analysis

Table 1 shows Cronbach's Alpha reliability test result for all six variables. The results revealed that 4 out of 6 outcomes ranged between 0.908 and 0.9066. This represented excellent scores that were highly reliable and dependable and considered valid for the present research. Such results were therefore, up to par with the rule of thumb, alpha > 0.9 (Davis, 1989). Nevertheless, Personalisation (P) indicated an alpha value of 0.876 whereas Customer Satisfaction (CS) exhibited a value of 0.886. It demonstrated great reliability and internal consistency, which reflected our scale from the general Cronbach alpha scoring observation of 0.929 out of the overall 30 item factors.

Normality Analysis

The Normality Test compared the outcomes of the sample with the normal distribution of outcomes, and with the same mean and standard deviation, which revealed that the null hypothesis was normal test distribution (Ghasemi, 2012). The skewness of the normality test measured the symmetry of the data distribution whereas the kurtosis measured the flatness and skewness of the data distribution. In accordance with Hair et al., (2010) the kurtosis and skewing values should ideally be between -1 and +1. Nonetheless, both values were between the range of -2 and +2 (George and Maller, 2010) in this present study. However, the overall data verification was still considered to be a normal univariate distribution.

Table 2 shows the normality test lead for all variables/constructions in this study. The results revealed that the general information with normal distribution fell within the range of -2 + 2 in the acceptable range. According to (Hair et al, 2010) if the skewness and kurtosis of a normality test possess a value between -2 + 2 it is considered close to normal and good as a rule of thumb. This is because when the values of skewness that fall outside this range indicate a substantial skewed distribution. Additionally, the kurtosis statistic in this research revealed a satisfying overall normal distribution except for 7 of the following variables: IS3, IS5, DP2, CS1, CS5, PR2, and PR3 that fell outside of the normal range score, which is between >-2 and > +2. Although the score was not within the kurtosis' excellent rule of thumb in relation to a few factors, it was still acceptable because all the variables had skewed the symmetry of the distribution. (Ahuja, 2010). Therefore, in this study, it was necessary to view the collected data as part and parcel of a normal distribution.

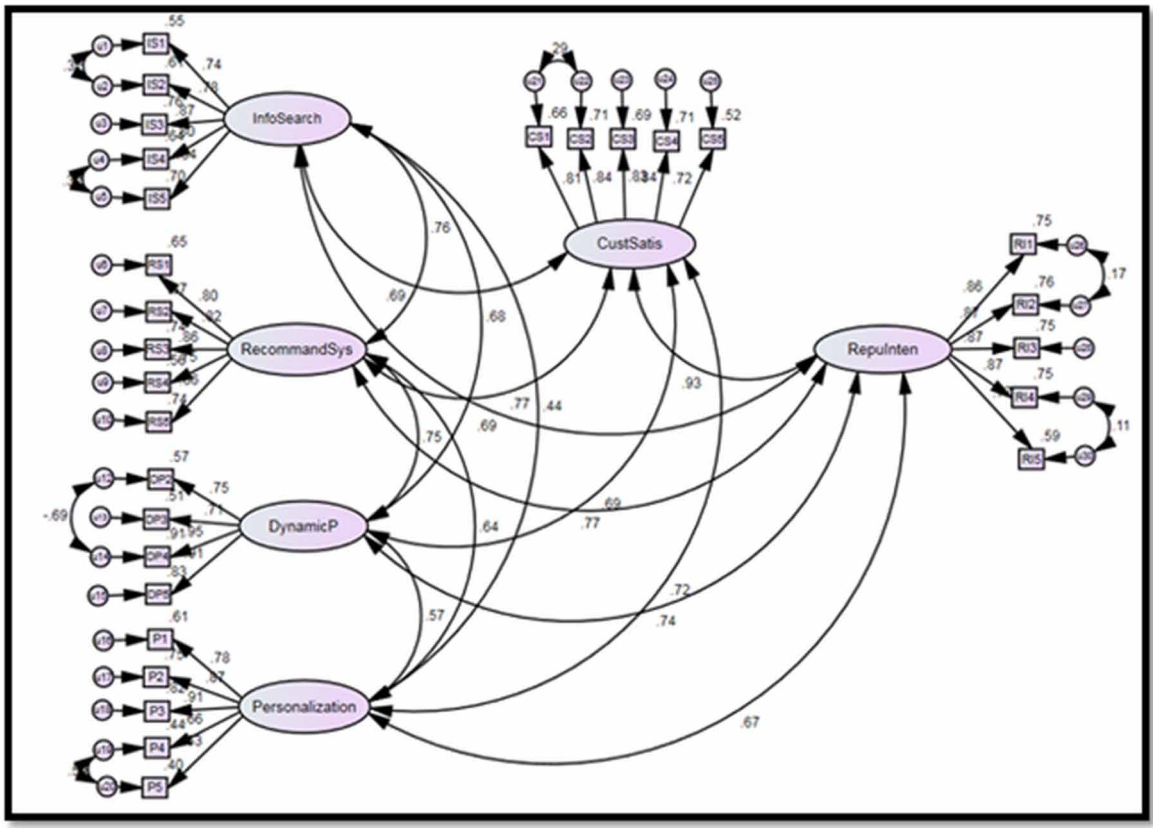
Figure 2. Confirmatory Factor Analysis



Confirmatory Factor Analysis

The overview of CFA results is shown in Table 2. The CFA outcome showed that the model of this study was justified to be an acceptable and healthy fit model, which was within the acceptance phase of all the values. The chi-square showed a statistically significant value of 0.00 outcome for the general model of suitable assessment in the present study (Müller, 2008). The RMSEA result with a value of 0.079, which was less than 0.008 showed that the mode of this study was good (Hooper, 2008). There was an increase to 0.915 in the Comparative Fix Index (CFI) and the Incremental Fit Index post-modification because the statistical range was between 0.0 and 1.0 with a value close to 1.0 that suggested an excellent fit. (Hair, 2006). The enhanced CFI value was justified based on the rule of thumb for the CFI value > 0.90 and was accepted as a healthy fit (Prudon, 2015). The Chisq / DF was also up to 2,980 and the value was < 3.0, in which it was in the appropriate range (John, 2009). This research proceeded to validate the hypothesis pertaining to the CFA's dimension of the model of fit to analyse the impact of the outcome when the big data analytic factors were applied to examine online shopping consumers' satisfaction and repurchase intention in Malaysia.

Divergent validity

The factor loadings were employed to validate different measurements to confirm the reliability of the data from the Cronbach's alpha.

Table 3. Summary of CFA Result

Indices Category	Index	Level of Acceptance	CFA Result	Decision
Absolute Fit	Chisq	P < 0.05	0.000	Acceptable
	RMSEA	£ 0.08	0.079	Acceptable
Incremental Fit	CFI	>0.90	0.915	Acceptable
	IFI	>0.90	0.915	Acceptable
	TLI	>0.90	0.915	Acceptable
Parsimony Fit	Chisq/Df	<3.0	2.980	Acceptable

Discriminant Validity

Discriminant validity is the extent to which a construct is truly distinct from other constructs, thus high discriminant validity proves that a construct is unique and captures a specific phenomenon that other measures fail to (MacQueen, 1967). CFA provides two common ways of assessing discriminant validity. Firstly, the correlation between any two constructs and secondly based on the comparison of AVE. However, the most popular test is the correlation between two constructs and therefore this research made use of it.

Diagonal elements are made up of construct variance and the values that exist above the diagonals are squared correlations. Quintessentially, it is relatively similar to specifying the fact that the items that make up the two constructs could just as well make up a single construct. If the two-construct model fit is significantly different from that of the one-construct model, then the discriminant validity is supported despite the high correlation value of 0.9. Therefore, the data satisfied the discriminant validity samples because only the Purchase Intention and Brand Image had grappled with multi-collinearity problems of the correlation, which surpassed 0.85. Nevertheless, the rest showed good correlations. In brief, the construct validity, divergent validity, and discriminant validity with the support of a strong work of literature demonstrated that the model was suitable to take on the SEM (path analysis).

Structural Equation Modelling

The first SEM validation was without mediation effect, which removed the customer satisfaction factor and the validity of the structural model interactions and their respective theoretical hypotheses. The following results Chisq/DF = 3.105, a significant value which was above 3.0. This showed that the model was a good fit model (Hooper, 2008). The Comparative Fit Index (CFI) value for this study was at 0.935 and the IFI value was 0.935. These outcomes depicted a good fit model since the value was above 0.90 (Hair Et al, 2014). Moreover, the TLI value was 0.924 and above 0.90 and the RMSEA was 0.075. The RMSEA value was more than 0.08, which was an acceptable range (Hair et al, 2010) as shown in Table 4.

Reliability	0.966	.911	.908	.876	.886	.907

The modified SEM validity model with the mediation effect was considered to be in the acceptable range of a suitable fit with relevant results of the model-fit shown in Table 5. The following CMIN / DF value was < 3.00, the RMSEA value was < 0.080; and the IFI, TLI, and CFI value were > 0.90, which showed an appropriate model fit. (Hooper, 2008). The exam results of the report were Chisq / DF (2.980), CFI (0.915), IFI (0.915), TLI (0.902), and RMSEA (0.079). These results indicated a strong balance of the model with the empirical evidence of the validity (Hair, 2007). The path analysis comparison is given in the following section of hypotheses testing.

Comparison of Factor Loading

The other SME validity measurement was based on a factor generated from the calculated model (Harney, O., Hogan & Broome, 2012). The table below revealed that the loading from the measurements model and structural models were compared and were close to each and other. Therefore, this model was ascertained to be a good fit. The structural model was valeted via the path analysis. Therefore, the table below shows the relationship between the measurements and the structural model. This relationship was significant and close to each other. Therefore, it indicated that this was a good model fit, which denoted the significance of path analysis.

Table 8 shows and demonstrates the loading factor of the measurement model and the SEM model. The data proved that both models were similar with just a minimum differentiation from the EV and PI constructs. Evidently, the model was justified to be a good model fit. In Amos statistic, the estimated column measured the correlation strength of the research exogenous construct, and the value of correlation was always between -1 and +1. This value of correlation was above 0.85, which depicted a multicollinearity problem between two exogenous constructs. Therefore, the research correlation analysis showed that all the research variables were correlated with no multi-collinearity problems, between the exogenous constructs. Thus, this comparison just reinforced the model fit not to deter it but to undertake the path analysis.

Summary of Hypothesis Testing

The path coefficients of the hypothesis were H1 ($\beta = 0.190$ $p < 0.01$) and H2 ($\beta = 0.231$, $p < 0.01$), H3 ($\beta = 0.183$, $p < 0.01$), H4 ($\beta = 0.269$, $p<0.01$), H5 ($\beta = 0.816$, $p <0.01$) and H5d ($\beta = 0.364$, $p < 0.01$). On the contrary, H5a was rejected as a result of indirect effect (0.26 X 0.80) > direct effect of (0.22). At the same time, H5b, and H5c were rejected with a hypothetical test on the P-values that were greater than 0.05 (Cramer & Howitt, 2004). The information gathered proved to be practical and valid based on a series of tests such as normality, reliability, validity, the suitability of the CFA and SEM model, and the information testing, which led to a suitable range. Therefore, results showed a favourable and substantial impact ($\beta = 0.816$, $P < 0.01$) on the mediating effect of customer satisfaction between personalisation and repurchase intention. However, the results of the hypothesis revealed zero customer satisfaction mediation effect pertaining to information search, recommendation system, and dynamic pricing on the repurchase intention, with a non-significant value higher than 0.05. The big data analytic factors like information search, recommendation system, dynamic pricing and personalisation had a significant and direct impact on repurchase intention with a significant level lower than 0.01. Results showed that the proposed hypothesis H5, customer satisfaction had a significant and direct impact on repurchase intention. Therefore, customer satisfaction was a mediating variable in the relationship between H5d, personalisation, and repurchase intention. The information search, recommendation system, and dynamic pricing did not depend on the effects of customer satisfaction and their intention to repurchase. The type of mediation here is called as "partial mediation" since the direct effect was still significant after the mediator entered the model (Radzi, 2017).

DISCUSSION

This section discusses the impact of selected aplications of big-data analytics on repurchase intention. Discussion is mentioned for each of the big-data analytics factor viz. information search, dynamic prizing, recommendation systems and persionalization. The results revealed that the information search influenced consumers' intention to repurchase in the Malaysian online shopping industry. This supported the outcomes delineated by (Andrew, 2014; Adeline, 2006), which indicated that information search and online shopping website usability had a positive relationship with consumers' intention to repurchase. Moreover, if the online shopping website provides the necessary search information, it may change online shoppers' purchasing decisions (Pee, 2018). Hence to enhance the repurchase intention, this parameter will play a key role. The findings also showed that the system of recommendations had a positive impact on the consumers' repurchase intention. Previous works of literature and empirical studies (Yan, 2018; Ankush, 2017; Zhang, 2016) had validated the system of recommendation as one of the critical factors, which had positively and significantly affected online shopping customers' satisfaction and repurchase intention. Previous studies and empirical research (Vijay, 2018; Chaitanya, 2018; Shin, 2017) had acknowledged that dynamic pricing was a critical factor, which had a positive impact on online shopping repurchase intention. A subject that has gained imperative attention in recent years is dynamic pricing with competitive product pricing. It will therefore, be feasible to set the correct price for the various customer profiles to improve complete utility. As a result, one needs to gather all the required information about their purchasing, their sensitivity to certain variables, and what they are looking for in the industry to understand the customer.

It is tricky to recommend a strategy on dynamic pricing because it has a direct impact on the bottomline. It is crucial to consider aspects related to competitor pricing, differential pricing, situational pricing, etc. E-commerce is known for offering affordable deals, discounts, coupons, etc. and dynamic pricing should include these considerations too. The outcomes of this research showed that personalisation did not have a significant and positive impact on repurchase intention. Additionally, online shopping website advertisements that are relevant to customer preference will trigger the customer's need for repurchase intention (Chou, 2016). Furthermore, an online shopping email notification about product promotion will trigger the customers' intention to repurchase if the customers are satisfied with the online retailer (Thi and Shu, 2017; Chong, 2012). Personalisation can be done vis-a-vis interface, information listing, booking procedure, and various tips. There is a specific scope to develop the sequence of the stages based on the aspects of personalisation. Online commerce companies are recommended to identify personalised choices of the customers based on the past purchase records or a survey and design the personalisation strategy accordingly.

Earlier works of literature and empirical studies (Yusepaldo, 2018; Xin K L, 2018; Wajeeha, 2018) had corroborated that customer satisfaction had imperatively and positively mediated the repurchase intention and other factors in online shopping. Additionally, previous studies and empirical review stated that information search played a vital role in influencing online shoppers' satisfaction (Nebojša, 2019; Davis, 1989; Gupta, 2013). Radu's (2015) study supported that customer satisfaction on personalisation had a positive mediation effect on the intention repurchase. Based on our outcomes, some characteristics in the online stores were clearly more favoured by certain groups of users. These findings helped understand the decision-making styles of the customers and made it more feasible to customise an online store's user interface to better meet the expectations of the user. The application of huge data analytics provided positive customer satisfaction with a personalised online shopping interface and notification. However,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the finding revealed that factors such as information search, dynamic pricing, and the recommendation system did not have the mediation effect of customer satisfaction on the repurchase intention. Therefore, an online shopping company need not focus on the mediation effect of customer satisfaction on the information search, dynamic pricing, and the recommendation system to enhance repurchase intention.

CONCLUSION

This study had contributed a valuable amount of information pertaining to the four big data analytic factors such as information search, recommendation system, dynamic pricing, and personalisation and their impacts on repurchase intention. Besides that, this research also intended to examine the mediation effect of customer satisfaction among the big data analytic factors and repurchase intention. The findings concluded that the four big data analytic factors had directly encouraged the customers' repurchase intention and their overall satisfaction suggesting companies can enhance repurchase intention via application of these big-data analytic techniques. Personalisation had a secondary impact and significance on the mediation effect of customer satisfaction and repurchase intention. Therefore, the online shopping company needs to consider the importance of personalisation in customer satisfaction to boost their intention to repurchase. However, information search, a recommendation system and dynamic pricing will not have customer satisfaction mediation effect on the repurchase intention in the Malaysian online shopping industry.

Theoretical Contribution

There have been several studies on the impact of applied big-data analytics on consumer choice, consumer behaviour and purchase intention in the context of E-commerce (see. Le and Liaw, 2017; Lo and Harvey, 2012). The existing literature identify factors affecting online repurchase intention as website attributes, discounts, usability factors (see. Dastane, Goi and Rabbanee, 2020; Tham et al. 2019). However, the literature is scant when it comes to confirming the factors related to applied big data analytics and its impact on online repurchase intention. Besides, there is no specific measurement model and the structural model is developed by combining factors of big data analytics. Additionally, the mediation effect of customer satisfaction based on the Big Data Analytics elements and repurchase intention was limitedly researched too. Nevertheless, zero studies were done on the impact of big data analytics on customer repurchase intention mediated by customer satisfaction in Malaysia. Therefore, the current study fills the existing vacuum of understanding of the subject matter. This study determined the effect of big data analytics on the online consumer repurchase intention in Malaysia. Furthermore, the present research also examined the mediating effect of customer satisfaction based on big data analytic factors such as information search, recommendation system, dynamic pricing, and personalisation and repurchase intention on online shopping. The current study offers a structural model of big-data analytic factors, customer satisfaction and online repurchase intention.

Managerial Contribution

The managerial contribution and recommendations to enhance the repurchase intention based on the application of big data analytic is discussed in this section. To imrpove consumers' repurchase intention,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

it is recommended that, E-commerce business include functions such as 'search' and 'sort' to facilitate an easy search as well as filter the information as required by the user. In general, E-commerce websites come with a list of hundreds of products, services, packages, etc., but not necessarily, every user is looking for such a massive range of information. If the online portal provides the platform for users to obtain the information that they are looking for, it can ultimately be reflected in the added value and positively attract repurchases from the same users. Even if most of the big players provide these facilities, various innovative ways can be adopted to facilitate the easy search to stand apart from the competitors. Online shopping websites can recommend substitute goods for the products that the customer intends to buy. This will therefore, simulate customers' repurchase intention if the customers have a good online shopping experience (Chen, 2012). Furthermore, online shopping website can recommend complimentary comments for the products that the customers want to buy (Celik, 2016). Thus, the online shopping website is recommended to develop an excellent system to provide the appropriate product and service recommendations. Such recommendations can be based on consumers' past purchases or from the customisation point of view. This can enhance users' intention to repurchase via the online shopping industry. Subsequently the recommendations on the mediation effect of customer satisfaction within huge data analytic factors such as information search, recommendation system, dynamic pricing, and personalisation on the intention to repurchase online. Firstly, the online shopping platform should ensure a convenient browsing system and a use-through product and service with an equivalent number of experiences from different devices. Secondly, online shopping platforms should set up a push notification on the latest sales and promotion, and create a wish list, which functions effectively with a click of a keypad. Thirdly, the online shopping platform should give customers exclusive notifications on discounts and promotions. Fourthly, the online shopping platform should allow customers to filter for the specific price that customers look for. Lastly, online shopping platforms should provide frequent shoppers access to exclusive events, rewards, and gifts with purchase.

Limitations

Nevertheless, the study had several limitations. This study was conducted for general online shopping and did not focus on a specific industry such as apparel or electronics. The majority of the respondents are Malaysian Chinese, and so generalizing these results for entire Malaysia will have some limitations. Instead of snowball sampling, if stratified or quota sampling is used, then appropriate representation of Malaysian population can be obtained in the sample. Besides that, the sample was not diverse because the majority of the respondents were Chinese. The study used limited big-data analytic factors. This study further recognised that the respondents were the Malaysians, which ultimately limited the scope of the study. However, the outcomes of this study were worthy and applicable to the developing ASEAN region. Lastly, online repurchase intention is affected by several other factors and enhancing the same depends not just only on the application of big-data analytics. The current study limits on the discussion of how factors of application of big data impact online repurchase intention and may help in enhancing the same to some extent, however, one should not conclude that these are the only factors contributing to increase in online repurchase intention.

Future Research

Nonetheless, future studies may focus on the concept of cross-culture and make comparisons between a wide range of countries or continents. Secondly, the present study used the user's response as a dependent variable. Even though the users' view is frequently used as a surrogate measure of behaviour, it does not accurately predict the actual buying situation. Thus, the results found in the present study should be understood and practiced with caution. Nevertheless, similar future studies should measure to fit in actual online shopping behaviour such as information search, real recorded ordering, and purchase amount as a dependent variable. Thirdly, the longitudinal approach is recommended for future research to explore other impacts of applying big-data analytics and capture the change of customers' responses. In the future, the study can be extended to a specific sector. Such validation will provide distinct findings in distinct sectors and further determine the model's effectiveness. Besides that, future research can enhance the number of factors and use other variables in the study that have been shown to influence customer satisfaction and their buy-back intent to understand the unusual satisfaction of other contributors and the level of intention to buy-back.

KEY TERMS AND DEFINITIONS

Applied Big Data Analytics: Applied big-data analytics is an application or integration of big data analytics in business operations with the intent of continues tapping and processing of big data to ensure identification of trends in order to assist better, faster and accurate management decision making.

Big Data: Big data is a combination of structured and unstructured data which is abundant in quantity, variety as well as the rate at which it gets generated resulting in a complex data set which cannot be stored, managed and processed by conventional statistical tools.

Big Data Analytics: Big data analytics is the use of advanced techniques to analyze, process and examine big data to uncover hidden patterns, trends and relations in order to assist management decision making.

Big-Data-Driven E-Commerce: Big-data-driven e-commerce is an e-commerce business which, through applied big data analytics, peek into its past trends, performance, and growth to improve customer satisfaction, increase revenue, gain new customers, and streamline its operations.

Online Repurchase Intention: Consumers' intent to purchase a product or avail a service repeatedly from the same e-tailer it termed as online repurchase intention.

Chapter 47
The Role of Reputation on Trust and Loyalty: A Cross-Cultural Analysis of Tablet E-Tailing

Sunday Adewale Olaleye

University of Helsinki, Helsinki, Finland

Dandison C. Ukpabi
University of Jyväskylä, Jyväskylä, Finland

ABSTRACT

The purpose of this article is to empirically examine the role of online retailer's website reputation on tablet commerce and to compare the trust arbitration between reputation and loyalty in two cultures - Finland and Nigeria. Data was collected from Finland and Nigeria, using purposive and snowball sampling methods. This article uses Structural Equation Modelling and mediation analysis. The results reveal that the reputation of online retailer's website is not a direct determinant of loyalty for online shopping while trust colligates with ease of use. The effect of an online retailer's website reputation is stronger in Nigeria than in Finland and trust is a strong predictor of ease of use in Finland than Nigeria. Furthermore, trust fully mediates the effect of reputation on loyalty in Finland and partially mediates the effect of reputation and loyalty in Nigeria. The implication of the result on existing and future managers were discussed with future direction.

1. INTRODUCTION

Tablet, a content consumption device emerged with a surge adoption to substitute laptops, complement smartphones and play an additional supplementary role in mobile commerce globally (Lee, Lee and Chan-Olmsted 2017). Conversion of consumers to online shoppers is one of the tactics of online retailers to engage customers and drive more sales while shoppers are on their websites. To have a consistent conversion of online visitor to a potentially loyal customer, there is a need to know the trait and cultural differences of online shoppers with a tablet. Chen, (2013) study reveals how culture impact tablet sharing across individualistic and collectivistic culture based on domestication approach and discovered ages, locations, and situations as the key themes that drive how people interact with a tablet. The speed of the change in the mobile technology industry is creating an opportunity for online retailers to use trendy computer devices to track customer's changing purchasing behaviour and to enhance online retailer's strategy and business model. Advanced technology like the tablet is impacting mobile commerce lifecycle from pre-purchase, purchase to post-purchase activities, thus, and making m-commerce a scalable business (Shankar, Kleijnen, Ramanathan, Rizley, Holland, and Morrissey, 2016).

Tablet commerce is now an offshoot of m-commerce, and it is "any transaction completed on a tablet device in which a payment is rendered through the device either through a retailer's website, through a proprietary 'app', or through some swipe device attached to a tablet" (Forrester 2011, pp.15). There is a limitation to this definition, and the conceptualization of tablet commerce is still at its formative stage. This study defines a tablet device in the context of m-commerce as a multitasking device that emerged to substitute the obsolete technology, complement existing mobile device and supplement the m-commerce strategy of an online retailer.

To the best of our knowledge, studies are scarce on cross-cultural contexts in the domain of tablet research, however, extant studies only cover cross-national study within developed countries (Jin, Park and Kim (2008). Other related studies are the impact of a tablet on human behavior with ethnography for communities - interpretive research method (Burford and Park 2014). Also studied is tablet use prediction – focusing on the gratification of tablet use with telephone survey (Leung and Zhang 2016) and impact of a tablet on digital commerce with experiment (Xu et al. 2016). Lee, Lee, and Chan-Olmsted (2017) also evaluated tablet diffusion with secondary data set; tablet apps with structural equation modeling - SEM (Kim and Kim 2016); tablet usage in the context of underdeveloped primary schools with Chi-square test and correlation (Pruet, Ang, and Farzin, 2016); impact of m-business with mixed-method approach (Picoto, Bélanger and Palma-dos-Reis 2014). All these studies emphasized the importance and challenges of a tablet as a medium of online shopping engagement between the online retailer and the consumers.

From the foregoing, this study seeks to answer the following research questions: 1) How does trust arbitrate between the reputation of e-tailer's website and loyalty of tablet users for online shopping? 2) How does trust colligates with online shopping easiness? 3) How does cross-cultural difference affect tablet commerce? This study makes key contributions to marketing and mobile commerce literature by developing a conceptual framework, linking the relationships between e-tailer's website reputation, trust and ease of use to predict loyalty in a cross-cultural context. The rest of the study is organised in the following ways: section 1 introduced the study. In section 2, the study discusses the theoretical background and hypothesis development. Section 3 deals with research design and methodology while in section 4, we treat the data analysis and results. The study concludes in section 5 with the discussion and implications.

2. LITERATURE REVIEW

One of the most significant facts regarding e-commerce disruption in recent years is how a tablet is growing faster and challenging the use of existing mobile devices like a smartphone. The integration of tablet devices into online retailing business is diffusing steadily (Shankar et al. 2016), and it is becoming easier for the online retailer to engage online shopper with gamification and mobile marketing techniques such as mobile advertisement and promotions. Tablet usage is growing, and its application and relevance to m-commerce have attracted the online retailer's reputable website, trust, and ease of use as a premise for online customer's loyalty. A reputable website is a bridge between the online retailer and online consumer but can this reputable website stand alone to impact loyalty? This m-commerce study postulates that reputable website despite its efficacy is not sufficient on its own to influence customer repeated purchase and loyalty. Extant studies see the aesthetic and ergonomic website as a means of assessment of online retailer by the online consumer (Kim and Lennon 2013, Ye et al. 2014, Oyibo, Ali and Vassileva 2016; Toufaily and Pons 2017).

There is a link between e-tailing website and factors like trust, ease of use and loyalty but the understanding of their meeting point need more insight. Despite the importance of trust and vast research area, its application to mobile commerce still needs more clarity (Yoon and Occeña 2015). Since many risks associated with online shopping and the online shoppers are being careful not to lose their valuables, trust becomes an essential component of consideration for the online retailer when targeting tablet users (Moriuchi and Takahashi 2016). Engaging with a cumbersome website is a time wastage process, and the online consumers are scared to shop on a static website that is not interactive. Ease of use construct by Davis (1989) encourages easiness, and when applied to online shopping, an easy to use website will facilitate easy checkout and prevent consumer drop out at the point of sales conversion. Due to the gap in the research stream of cross-cultural studies in the developed and the developing nations (Oyibo, Ali and Vassileva 2016), this study aims to fill the gap by choosing one notable country in Europe that is renown in technologies and internet penetration and another country in Africa that is growing in technologies and internet penetration (Grewal, Bart, Spann, and Zubcsek, 2016; Oyibo et al. 2016). To determine what makes a country developed and developing, the authors used the postulation of the United Nations on Human Development Index (HDI). This metrics is a composition of life expectancy, education, and national income. Finland (developed country) rates 0.88 and ranks 24 globally while Nigeria (developing country) rates 0.51 and ranks 152. The threshold of this ranking is 0.8 (UNDP 2015).

2.1. The Role of Culture on Tablet E-Tailing

Collectivist and individualistic cultures have different characteristics. While interdependence and group cohesion are the dominant social traits in a collectivistic culture, independent lifestyle, self, personal goal setting, and attainment are the fabrics of an individualistic culture (Hofstede 1980; Hofstede and Bond 1988; Gudykunst, Ting-Toomey and Chua1988; Hofstede et al. 2010; Hofstede 2014). From the consumer behavioural perspective, these cultural traits also influence purchase decisions. Accordingly, Kacen and Lee (2002) contend that the inherent independent lifestyle of the individualistic cultures exposes them to the hedonic gratification of desires. To the collectivistic culture, the individual's allegiance to group subjects them to emotional control and moderation. Interestingly, several studies have also examined cultural differences in user preferences for the characteristics of websites design (Marcus and Gould, 2000; Sun, 2001; Cyr, Bonanni, Bowes, and Ilsever, (2005); Al Badi and Mayhew, 2004; Al-Badi, 2009).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Specifically, Marcus and Gould (2000) submit that websites oriented in individualistic cultures tend to emphasize personal achievement, materialism/consumerism, and prominence usually given to youth and action. Conversely, they argue that websites rooted in collectivistic cultures tend to explicate such values as experience, leadership, age, status, tradition, and history. In corroborating this, it is reported that the Finnish desired websites with fewer colors and lowest visual complexity but Nigerians prefer a website that is rich in content and aesthetically pleasing (Lab in the Wild, 2014; Raji, Mahmud, Tap and Abubakar (2014). However, it is important to point out that marketers aiming for the global audience should integrate dynamic website features that meet the need of each culture based on individualistic and collectivistic traits (Würtz 2005). Besides cultural factors, some studies have examined additional supplier-consumer centric variables that fundamentally influence cross-cultural purchase decision such as reputation, loyalty, trust, and ease of use.

2.2. Reputation

Reputation is how the customers estimate the worth of an organization regarding product quality and services. The unfamiliar online vendor needs to go an extra mile to assure its various customers of its legitimacy and trustworthiness (Pennington, Wilcox and Grover 2003). Abd-El-Salam, Shawky and El-Nahas (2013) and Sarstedt, Wilczynski, and Melewar (2013) established that a reputable organization differentiates itself in profit maximization, market share, customer acquisition and retention. Jin et al. (2008) empirically contend that a company's website influences its reputation and also an antecedent of consumer trust. Dijkmans, Kerkhof, and Beukeboom, (2015) argue that reputation of m-commerce is a predictor of trust and base their argument on how significant the perceptual experience of customers on corporate reputation influence their loyalty. Similarly, in Chang (2013) reputation was the strongest predictor of trust though however not a direct linkage of loyalty. This contrasts an earlier result which establishes a reputation as a direct linkage of loyalty (Selnes, 1993). In a related study, Xiong and Liu (2003), examined how community-based reputations aid evaluation of trustworthiness in e-commerce and recommends a reputation-based system that is adaptable to a different scenario and gave examples of eBay, Amazon, and Yahoo among others as e-commerce sites that have reputation management systems. Culturally, the perception of a reputation as a virtue varies between the individualistic and collectivistic cultures. Accordingly, due to low trust and high respect in the collectivistic cultures, the external frame of respect is valorised (Park and Kim, 2008), implying that reputation, which is a critical embodiment of the external frame of reference is coveted as a virtue. In business relationships, companies in the collectivistic cultures engage in strategic manoeuvres to maintain reputable status in the market. A reputable website is a necessary tool in online shopping, and it is a strong determinant of sales conversion. Aesthetic e-tailing website with easy navigation, privacy and security assurance will be more attractive to the online consumer. Establishing a dynamic website may be cumbersome but it is worth any investment that online retailer might give. Online shoppers are always looking for an optimized website that can meet their goals and objectives. Following this, we thus argue that:

H1: Reputable e-tailer's website will positively influence the loyalty of the consumers to use a tablet for online shopping.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.3. Trust as an Antecedent of Customer Loyalty

The interdisciplinary studies of trust (Salo and Karjaluoto 2007) and its different definition call for closer examination despite its vital interest to build a relationship (McKnight and Norman 2001, Pennington et al. 2003, Gefen, Karahanna and Straub 2003). A trusted m-commerce website builds confidence and gives assurance to the online consumer to carry out their online shopping without fear of losing information such as their credit card and other vital information to the wrong hands (Ribbink, Van Riel, Liljander, and Streukens, 2004). Trust creates an interpersonal situation when the m-commerce consumer trusts the online vendor and becomes institutional when the consumer trusts the website they are using for online shopping (McKnight and Norman 2001, Pennington et al. 2003). Due to lack of human interaction in online shopping platform, it takes time to build a trusted website. The rigour of building it will contribute to influence online consumers' decisions (Gefen, et al. 2003; Nilashi, Ibrahim, Mirabi, Ebrahimi, and Zare, 2015; Kim et al. 2016). Trust is a major component of e-commerce and it has the potential to raise the customer's high expectations of gratifying exchange relationships between the m-commerce vendor and the online shoppers with a tablet (Xiong and Liu 2003; Pennington et al, 2003). Trust is a determinant of a consistent loyalty of online consumers. Nilashi et al. (2015) classified trust into low, moderate and high trust emphasizing the degree of trust based on other variables like gender. The cultural element of trust is an influencer (Doney, Cannon and Mullen 1998; Jin et al. 2008). Jin, et al. (2008) examined customer loyalty and trust on a cross-cultural basis. They found that individualistic cultures are high trust societies, thus loyalty formation is more difficult than in collectivistic cultures. Trust is a critical path to building a long-lasting relationship between the online retailer and online consumer (Nilashi et al. 2015; Lee et al. 2015). Lin and Wang (2006) found that trust positively predicted loyalty and a direct linkage to loyalty.

Customer loyalty in m-commerce is gaining popularity (Lin and Wang 2006). Anderson and Srinivasan (2003, p.125) defined loyalty "as the customer's favourable attitude toward an electronic business resulting in repeat buying behaviour". A customer that repeated purchase is a target of conversion to loyalty by the online retailer, and the customer loyalty is paramount in online retailing because it tends to pay back in long-term with profits (Ribbink et al. 2004). Unlike conventional brick and mortar store, loyalty programmes adopted in m-commerce should play a complementary role to a reputable website. Customer loyalty is one of the pillars that holds mobile business and it is important for m-commerce merchant and vendor to have a proper understanding of how loyalty evolves because loyalty is germane to m-commerce success (Anderson and Srinivasan 2003, Lin and Wang 2006). Chaudhuri and Holbrook (2001) posit that commitment on the part of the online retailer will facilitate an easy repeat purchase intention while Orel and Kara (2014) saw checkout service (SCS) as a positive influence on loyalty. In examining loyalty on an e-commerce platform, Srinivasan, Anderson, and Ponnavolu (2002) posit that customization, contact, interactivity, cultivation, care, community, choice and convenience constitute critical antecedents to e-loyalty. However, few years later, Harris and Goode (2004) contend that trust occupies a pivotal role as an antecedent of e-loyalty which was valorised by Martínez and del Bosque (2013) by arguing that trust positively mediates as an antecedent of loyalty in the hospitality services thus very critical on the online customer to make a repeat purchase. Accordingly, this study argues that trust intermediates between reputation and loyalty through the following hypothesis:

H2: Reputation of e-tailer's website will positively influence the loyalty of the consumers through trust.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H3: Consumer loyalty to use a tablet for online shopping increases when there is perceived trusty e-tailer's website.

2.4. Ease of Use

Ease of use is one of the constructs of the technology acceptance model (Davis, 1989), and it was a predictor of intention of the user to adopt a technology. Ease of use depicts the perception of a technology user that the new technology will be less complicated. Many researchers have adopted and adapted the construct of ease of use in their studies. For example, Kucukusta, Law, Besbes, and Legohérel, (2015) use perceived usefulness and ease of use to test the intention of the tourist to purchase online. Agrebi and Jallais (2015) used ease of use as a predictor of intention to use a smartphone for online purchase but was not significant. Contrary to the result of Agrebi and Jallais (2015), Ozturk, Bilgihan, Nusair, and Okumus, (2016) found the ease of use to be significant as a direct linkage with loyalty just as an earlier study (Gefen, et al. 2003) found the ease of use predicted trust. The postulation of trust predicting ease of use is consistent with the study of McCloskey (2006). This antecedent indicates that the lack of trust elements on m-commerce website such as privacy and security will create tension for an m-commerce website user. To ensure a tension-free online shopping experience tablet e-tailers should put some safety and confidentiality checks in place to protect their valuables and earn the trust of the consumers. Thus, we argue that:

H4: Perceived trusted e-tailer's website with a tablet is positively associated with ease of use.

3. RESEARCH DESIGN AND METHOD

3.1. Sampling and Data Collection

Our most important target population for this study is the tablet owners and tablet users in Finland and Nigeria. In the study, the tablet owners are those that have any brand of tablet in their possession, and the tablet users are those that have a tablet in their possession or borrow it to carry out an online transaction. As a collectivistic culture, borrowing an item including electronics such as a tablet is common place, however, such practices may be rare in an individualistic culture like Finland. Bezzina and Saunders (2015) accentuate sampling and we used purposive and snowball sampling to recruit the participants of our survey. Snowball sampling was utilised in Nigeria being a communal country while purposive sampling technique was employed in Finland being an individualistic culture. First, we targeted opinion leaders and those that are influential. Second, we explained the focus of our study to them and sought their assistance for the data collection. Third, we worked with the opinion leaders directly to get feedback on the data collection and finally get 383 and 167 self-administered questionnaires distributed through them (see Table 2). In total, we got 800 responses, but because our targets are the owners and the users of the tablet, we screened the responses to 550 in both countries. In line with Dai and Palvi, (2009) and Chen, Zhang, and Lee, (2013), data collection took place in university campuses in both countries. The Millennials dominate the campus environment. They constitute 61.1% and 82.8% of the total samples, and they used mobile devices more than the older generations. We are motivated to use the campus respondents because of their hankering for technology (Persaud and Azhar 2012). The participants of the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

survey males in Finland and Nigeria are 46.71%/59.5% while the females are 53.29%/40.5%. Among the participants, the lower income earners are higher in Nigeria with 74.7% as against 22.8% in Finland. The bachelor degree holders were the highest participants in Nigeria with 64.8% and high school/diploma holders in Finland with 42.5%. The participants of the survey have one time or the other search for the information or buy goods online with their tablet.

A 51-item questionnaire designed with 22 items related to demographic and general questions targeting the respondents' bio-data, livelihood, exposure to online shopping and education background information. Additionally, the authors inculcate 29-item sequel to the tablet users' shopping experience and disposition to mobile commerce. The tablet users' perception was measured using a seven-point Likert scale (1 = strongly disagree, 2 = disagree, 3 = slightly disagree, 4 = neutral, 5 = slightly agree, 6 = agree, 7 = strongly agree). The scale used to measure website reputation was based on Li (2014), while the study adopted scales from Lin and Wang (2006) for trust and loyalty. The scale for ease of use was based on Davis (1989). The items used to measure each construct are listed in Table 3. Table 1 shows the demographics in Finland and Nigeria.

4. DATA ANALYSIS AND RESULTS

To ascertain the reliability and validity of measurement of items used in this study we took the following steps. First, we measured the scales' reliability (Cronbach's alpha) with 0.7 as the threshold value with SPSS 22.0. All the items align with the Cronbach's alpha threshold. A confirmatory factor analysis was performed to test the convergent and divergent validity of the scales. Second, we advanced scale reliability based on the indicators extracted from the confirmatory analysis using composite reliability (CR) and average variance extracted (AVE) with the rule of thumb of 0.7 and 0.5. All items reached the stipulated threshold except loyalty construct with marginal average variance extracted (AVE) in both countries. Third, we tested the research hypotheses reviewed in the extant literature using structural equation model (SEM) with Mplus version 7.4. Fourth, we conducted mediation analysis (see Table 6 and Figure 2 for details. We tested several models to ensure model fit for the study. Once we conclude on the validity of the model modification, the result reflects in a graphic as a behavioral model that reveals the trust arbitration of reputation and loyalty (Table 3).

We examined the squared multiple correlations for a structural equation with Mplus software to test the hypotheses. The result of the analysis shows the correlation of reputation and trust H2: (β = 0.66/0.92). Trust correlate with loyalty H3: (β = 0.45/0.43), and ease of use H4: (β = 1.00/0.78). H1 was not supported but H2 – H4 fully supported. Reputation was a strong predictor of trust in Nigeria while trust explained the ease of use better in Finland. The way trust arbitrates between reputation and loyalty is consistent with the study of Jin et al. 2008 (see Figure 1 and Table 5 for details). Table 4 shows the SEM result for two countries.

The mediation analysis was computed as (P12 x P22 = 0.83/0.76 x 0.47/0.55) for indirect effect and P3 + (P12 x P23) = 0.39/0.42 + (0.83/0.76 x 0.47/0.55) = 0.15/0.23 + 0.39/0.42 = 0.54/0.65 for total effect as suggested by Hair Jr, Hult, Ringle and Sarstedt (2016). The result established mediation effects between reputation and loyalty through trust in the two countries and the total effect of the mediation is stronger in Nigeria than Finland (see Figure 2 and Table 6 for details).

6. DISCUSSION AND IMPLICATIONS

The objective of our study was to examine trust arbitration between reputation and loyalty in a cross-cultural context of tablet users for online shopping. To achieve this objective, four hypotheses were tested for which one was rejected and three accepted. Our study harmonizes ease of use from Technology Acceptance Model (TAM) with reputation, trust to predict the loyalty of online shoppers with a tablet. While considering the relationship between the reputation of the website and the customer trust of e-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

commerce websites, the perceived trust and perceived ease of use of e-commerce websites with a tablet can lead to gratification and then influence customer loyalty towards an m-commerce website across the borders. Additionally, the study integrates international cultural differences to ascertain the perimeter of collectivist and individualistic cultures thus offering critical theoretical insights.

Table 2. The latent variables used for the study

Constructs and Measurement Items
Website Reputation (Li 2014)
This m-commerce vendor is well known
This m-commerce vendor has a good reputation
This m-commerce vendor has a reputation for being honest
This m-commerce vendor has a reputation for caring about its customers
This m-commerce vendor has a reputation for being able to meet its obligations towards the customers
This m-commerce vendor has a reputation for being consistent
This m-commerce vendor has a reputation for fulfilling its promises
Trust (Lin and Wang 2006)
This m-commerce website is trustworthy
This m-commerce website keeps promises and commitments
This m-commerce website keeps my best interests in mind
This m-commerce website meets my expectations
Ease of Use Davis (1989)
This m-commerce website is easy to use
It is easy to become skillful at using this m-commerce website
Learning to operate this m-commerce website is easy
This m-commerce website is flexible to interact with
My interaction with this m-commerce website is clear and understandable
Loyalty (Lin and Wang 2006)
My preference for this m-commerce website would not willingly change
It would be difficult to change my beliefs about this m-commerce website
Even if close friends recommended another m-commerce website, my preference for this m-commerce website would not change
I will buy from this m-commerce website the next time I purchase the above-mentioned product/service

*Note: Items of the constructs adopted from the previous studies and amended for the sake of this study.

6.1. Theoretical Implications

Our study makes the following theoretical contributions: first, as expected, reputation-loyalty (H1) and reputation-trust (H2) links were stronger for Nigeria than in the Finland. This finding supports earlier studies that in collectivistic cultures which are markedly high uncertainty, high context and low trust, the external frame of reference (in this case reputation) is given high recognition (Heine, 2003; Jin, Park, and Kim, 2008). Additionally, technologically savvy Finnish users may prefer a website more sophisticated than the Nigerian user who is not so technologically advanced. Thus, for the Nigerian user, what leads to a website reputation may not necessarily be the sophistication of the website but its perception in the social sphere through interactions with relations and friends. Second, collectivistic cultures such as Nigeria are more tolerant and less demanding thus prone to trust easily as compared to individualistic cultures. This argument is further corroborated by the trust-loyalty (H3) which indicates a stronger link for the Finnish user than Nigeria. According to Jin, et al. (2008), individualistic societies are high trust societies, thus, loyalty formation is more difficult compared to collectivistic societies. Third, Finland is a country of high technology, thus revealing the impact of ease of use in the context of tablet usage. The

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Finns technology versatility is a plus while Nigerians are just rising to the challenge. On the trust-ease of use link (H4), this result reflects online shopping reality. For instance, there are a lot of aesthetic and well-optimised websites that lack sales conversion due to kibosh online shopping checkout. The fear of insecurity is one of the reasons responsible for this act. The strong link between trust and ease of use is an indication of tension free online shopping when the online shopping environment is conducive. In sum, with these results, our study is the first, to the best of our knowledge, to examine tablet e-tailing in the context of a cross-cultural comparison between Finland and Nigeria, thus, extending prior studies in this area. Also, the novelty of our study is underpinned by extending the e-loyalty literature by using trust as an antecedent in the tablet e-tailing context, thus, opening a research gap that could incorporate other e-loyalty antecedents to the tablet e-tailing body of research.

Table 3. Correlation among constructs

	Factor Loading (Finland/Nigeria)				CR	AVE
CA (α)	.935/.896	.932/.850	.736/.715	.891/.853

6.2. Managerial Implications

This study has some managerial implications for tablet commerce stakeholders. First, companies that are planning to extend their business to a new market through foreign market entry modes most especially, a Foreign Direct Investment (FDI) can minimize their entry barriers by harnessing the framework proposed in this study. This will help the managers to understand the cultural differences between developed and the developing nations regarding the impact of reputation, trust, and ease of use as an antecedent of building a loyal customer. Second, our results inform the managers that trust is bi-directional and the expectation from the both sides, the trustee and the beneficiary are the strong brand with value-added products, stupendous services, supportive after sales relationship and superior competitive advantage. This insight illuminates the merchants and the vendors to pay attention to the centrality of trust culture in relation to the merchant reputation and the customer loyalty of tablet users as they develop their customer´s loyalty strategy. Third, the understanding of the cultural difference between developed and the developing countries will boost the company's initiative to improvise an effective communication to reach customers outside their business boundary and strengthen the interaction of business relationship. This development will reduce and reverse anticipated business cultural shock and promote sharing culture across the borders.

6.3. Limitations and Future Research

In comparison with past studies, this study has some limitations which unlock insight for future research directions. We only limit our study to tablet usage and not a comparison between emerging mobile devices like smartphone and wearable for online shopping. However, our study focuses on the impact of the tablet for online shopping across developed and developing cultures. Future studies can work on this limitation and use the moderating effect of online shopping experience and age on the findings of this study. Finally, future study can also consider other established antecedents of loyalty such as satisfaction, value, service quality and price and how they influence customer loyalty in the context of tablet e-tailing.

ABSTRACT

This article describes how the exponential growth of e-commerce in India and the presence of many national and multinational e-retailers has set the trend for the major overhaul of the online industry. Most of the e-retailers have failed to differentiate themselves from the competitors. This has resulted in their failure to attract and retain the right set of consumers for their respective businesses. The present paper is aimed at identifying and developing the typology of online shoppers based on importance given by them to shopping values and web portal features. The data collected was analysed using factor, cluster and correspondence analyses. The article identifies four types of online shoppers – 'Information Seekers,' 'Utility Seekers,' 'Value Seekers' and 'Core Shoppers.' Each of these four segments display significant differences and this information can be strategically used by web retailers in targeting their markets effectively.

INTRODUCTION

An online market place is an entity where information regarding product or service is provided by a third-party seller followed by the execution by the operator of the market place. Commonly known as electronic commerce websites, these provide a convenient option for vendors to sell products or services without having a physical store. Electronic commerce (or e-commerce) has been defined as commercial transactions that occur between buyer and sellers over the internet while enabling new economic and business practices. The rapid emergence and acceptance of e-commerce has changed the structure and environment of businesses conducted in today's world. With the current GDP of India constituting at over US $2.48 trillion, and growing steadily at 7.49%, the Indian economy is pegged to be the fastest growing economy in the world (Economy Watch, 2017). With such high growth, online market places are expected to increase in number. Online retailing in India is estimated to grow from US $30 billion in 2016 to reach US $100 billion by the end of 2020 (IBEF, 2017). Positing several reasons for the rapid emergence of online market places in India, Gehrt (2012) attributed the rise of the Indian economy, purchasing power parity, large number of college students, and growth in telecom sector coupled with higher internet penetration in the country as major influencers. Ravichandran (2009) observed that the economic crisis of 2008 forced more people to compare prices with different retailers giving prominence to the online market places. In India, there exists a plethora of online market places, like Flipkart, Amazon, Snapdeal, Paytm, etc. Flipkart leads the pack with 44% market share, followed by Amazon at approximately 31% and Snapdeal 14% (Economic Times, 2017).

The exponential growth of e-commerce in India, coupled with vastness of the market, motivated the researchers to identify various online shoppers' segments on the basis of pertinent shopping values and web characteristics that have influence on the website selection. It has been anticipated that India would be in the top 10 e-commerce destinations in the world, but the online firms are posed with plenty of challenges (Vyas & Gupta, 2017). Despite the exponential growth of online retailing in India, not much research has been undertaken to understand and identify the online shopper segments in India (Gehrt et al., 2012). In the preliminary study, Gehrt et al. (2012) observed the presence of three segments: 'value singularity,' 'quality at any price' and 'reputation/recreation' on the basis of key shopping orientation themes and web site dimensions. A study by Pandey et al. (2015) on online shopping lifestyles in India identified three shopping segments, 'mature traditionalists,' 'offer enthusiasts' and 'technology mavericks,' and it concluded that internet self-inefficacy impacts mature buyers. It also observed that the offer-seeking shoppers, comprising mostly of students from lower age group, do not enjoy the convenience of online shopping. The major limitation of this study was the usage of parameters defined for American lifestyles in Indian context.

Studies have also been undertaken to identify consumers and firms' preferences in using internet marketing channels (e.g. Khatwani & Srivastava, 2015; Khatwani & Srivastava, 2017). A study in the Indian context by Prashar et al. (2017a) has noted that nearly sixty-four percent of variance in web satisfaction is explained by motivations based on shopping values and website characteristics. These motivations form an important dimension for online shoppers and can be used as basis for segmenting the shoppers. However, the earlier studies have not segmented shoppers on the basis of these motivations. Hence, the present paper is pioneer in classifying online shoppers as per their attitude towards shopping values and site features. It further explored the association, if any, between income groups and the identified segments using correspondence analysis. The paper is sequenced in the following manner. The next section details the research background and incorporates extensive review of literature. This is followed

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

by discussion on research methodology that includes the process of data collection. Data analyses using factor, cluster and correspondence analysis is available thereafter. The final section contains discussion of findings, implications and limitations of the study.

RESEARCH BACKGROUND

Online Market Segmentation

Segmentation is the procedure of categorizing and dividing individuals into homogeneous groups that have related features and/or display similar behavior, which would help marketers in developing strategies for fulfilling the segment's precise needs (Blackwell et al., 2001). Similar to the process of segmenting offline shoppers, many of the web related elements like portal's response time, transaction time, shopper convenience etc., have been used to categorize e-shoppers (Pandey et al., 2015). Nevertheless, it has been observed that shoppers' opinion about convenience differs across groups (Kaufman-Scarborough & Lindquist, 2002). Few of the consumers evidently prefer to buy in offline stores, whereas many others feel that switching between online and offline mode is highly convenient. The extant literature has many studies that have attempted to examine the underlying similarity among shoppers and segment them in homogeneous groups (e.g. Aljukhadar & Senecal, 2011; Bhatnagar & Ghose, 2004; Ganesh et al., 2010; Pandey et al., 2015; Prashar et al., 2016; Soopramanien & Robertson, 2007; Ye et al., 2011). These studies have used internet usage patterns, internet self-efficacy, perceived benefits, perceived risks, website selection factors, lifestyle differences, etc. But none of the earlier studies have attempted to segment the online shoppers on the basis of motives they seek with respect to shopping values and website characteristics. To fill this gap, the present study attempts to segment online shoppers based on their perception towards these predictor elements.

Shopping Values

Several researches have noted that both hedonic and utilitarian values are responsible for determining the consumption pattern (e.g., Babin et al., 1994; Sorce et al., 2005; Sebastianelli et al., 2008; Kim & Eastin 2011). Hedonic values have become an integral part of the buying process. First acknowledged by Holbrook and Hirschman during the study on sensory stimulation and pleasure in the buying process, hedonic shopping value (HSV) depicts the amount of entertainment and emotions one derives from shopping and can be specified by the augmented arousal, participation, perceived freedom, distraction, fantasy, and sensitive aspects of any shopping experience (Babin et al., 1994; Sorce et al., 2005). Hedonic consumption is characterised by fantasies, feeling and fun (Holbrook & Hirschman, 1982). On the other hand, utilitarian consumption takes place when a shopping tour is able to achieve a certain need, and reflects a certain, reasoning, and non-emotional outcome (Babin et al., 1994). As consumers' demands have changed over time, frameworks used in capturing of shopping experiences have also shifted. Fiore and Kim (2007) proposed a shopping experience framework based on stimulus-organism-response in accordance with the shift. In their study on characteristics of retail stores that have differential impact on shopping values, Ottar et al. (2011) concluded that utilitarian shopping value is positively associated with merchandise collection and physical characteristics of the store. The researchers also observed the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

negative impact of store features on hedonic shopping values, and salespersons interactions was negatively related to utilitarian shopping values.

Lim (2014) examined the impact of online flow (i.e. arrangement of elements in a website) on hedonic and utilitarian shopping. The authors posited that arousal, challenge, telepresence, and time distortion have been linked to hedonism, whereas control, importance, interactivity (speed) and skill have been linked with utilitarianism. Also, in a promotional context, hedonic premiums are preferred over utilitarian premiums, with any other characteristics of premium being the same (Palazon & Delgado-Ballester, 2013). When affective or cognitive reactions are incited, an inclination towards hedonic or utilitarian is more likely to arise.

Hedonic online shoppers tend to look for special experiences taking into account their capacity to upgrade the joy and amusement of online shopping (Wolfinbarger & Gilly, 2001; To et al., 2007; Prashar et al., 2017a). In comparison, utilitarian online shoppers concentrate on the practical functions for the online encounters, like product quality, price, ease of use, and other shopping related elements (Sorce et al., 2005, Vijay et al., 2017a, Vijay et al., 2017b). Studies on online shopping have found that shopping inspirations like hedonic and utilitarian quality can influence shoppers' states of mind about online shopping (e.g., Childers et al., 2002; Chiou & Ting, 2011). Ajzen (1991) stated that attitude while shopping also contains a reasoning factor. Spangenberg et al. (1997) suggested that hedonic worth was experienced on cognitive levels, while the utilitarian part is ruled by the cognitive component.

Yuksel (2007) demonstrated that utilitarian shopping esteem impacts shoppers' practices, in spite of the fact that the impact is weaker than that of hedonic value. According to Kim et al. (2014), buyers' individual contrasts in their online shopping encounters impact their apparent shopping worth and shopping cost with regards to online shopping.

Web Informativeness, Effectiveness and Entertainment

Usability is an important requirement for effectiveness and success of online shopping websites. Besides facilitating and achieving customer satisfaction and increases reliability, it also helps in better and easier navigation through the website (Mario et al., 2007). Enrique et al. (2008) posited that pre-purchase online information influences future shopping intentions directly and positively. Richard et al. (2010) showed that enjoyment or pleasure from a web portal can be an important dimension of online shopping experience. Buyers with positive information and convenience attitudes towards e-commerce had higher online purchase intention (Patricia, 2006). Similarly, Gao et al. (2014) posited that there are three components related to web atmospherics – informativeness, effectiveness and entertainment, that influence shoppers' intention to purchase a product and satisfaction received in the process. Using a website, whether a consumer perceives it to be challenging or not depends on the level of information correctness, significance, appropriateness, comprehensiveness, and convenience. A study by Vijay et al. (2017b) also noted positive and significant influence of these three factors on shoppers' satisfaction. Kim et al. (2009) observed a positive effect of product presentation on shoppers' emotional and cognitive states.

Thus, we can conclude that factors influencing shopping can be either intrinsic or extrinsic in nature. Hedonic and utilitarian values that are intrinsic in nature indicate the reasons of pleasure, being at ease and deriving utility, whereas web atmospherics, which is extrinsic in nature, is associated with characteristics of the shopping website.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

RESEARCH METHODOLOGY

The study was carried out in two stages. The first stage encompassed examining of the present work on online market segmentation and various factors that influence online shopper's behaviour. After going through the literature and keeping the objective of the study in focus, five different constructs that were associated with shopping values and web portal features, were identified. The construct 'shopping value' had two elements – hedonic and utilitarian shopping value, whereas, the construct for 'web portal characteristics' consisted of web entertainment, web informativeness, and effectiveness of information content. On the whole, twenty items for the five factors were identified. These twenty items were converted into statements and were incorporated in a questionnaire, which was used for data collection. To ensure the validity of the items, all these statements were taken from earlier validated studies. A seven point 'Disagree-Agree' Likert scale was used for measuring responses, where 1 represented "Strongly disagree," and 7 represented "Strongly agree." Before proceeding with data collection, the survey instrument was pilot tested with thirty-five students pursuing their doctoral degree in Management. Requisite changes were made as per the suggestions and the scale was found to give valid and reliable output.

The second stage of the research consisted of collecting data using the instrument, which also had questions about respondents' age, gender, marital status, education level, occupation, family's monthly income, and frequency of visiting online retailer per month. The present study used a cross sectional design with the idea that the sample units represent the population. The Indian online shoppers of eighteen years and above age were eligible for participation in the research. The sampling extent was defined as those shoppers who had at least bought three times in the last six months from any of the online stores. The data was collected from three major Indian cities of Delhi, Mumbai and Bengaluru. A total of 410 respondents participated and filled the survey. After eliminating the erroneously/incompletely filled questionnaires, the researchers were left with 319 data points that were used for data analysis.

DATA ANALYSIS AND INTERPRETATION

Three techniques were used for data analysis. Initially, the data was subjected to exploratory factor analysis. This was undertaken to ratify the existing factor structure. The second stage involved cluster analysis to segment the shoppers into homogenous groups. Finally, correspondence analysis was used to identify association between income levels and segment of shoppers.

Factor Analysis

The twenty items were subjected to exploratory factor analysis for confirming the factor structure. Five factors were recognized and this solution explained 72% of the total variance. The value of Bartlett's test of Sphericity (=3837.880) and sampling adequacy, as explained by KMO test (=.909), confirmed the suitability for factor analysis. Cronbach alpha values for the five factors were found to be greater than 0.65. Hence, the scales used for the study can be considered as reliable. These five factors were related to hopping values and website characteristics. As shown in Table 1, factors were named according to items comprising each of them. These factors are – 'web entertainment,' comprising five items that pivoted around fun and excitement; 'web informativeness' with four items related to informativeness and resourcefulness; 'effectiveness of information content' having four variables focusing on accuracy;

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

'hedonic shopping values' with four elements related to pleasure of shopping; and finally, 'utilitarian shopping values' with focus on usefulness and utility in the process of buying goods:

- **Web Entertainment (WE):** This set of variables explaining 41.44% of the net variance, comprised of five items – fun, excitement and entertainment while browsing the website, and imaginativeness and attractiveness of the website. Since all these factors revolve around the entertainment derived from browsing the website, and hence is termed as web entertainment;
- **Web Informativeness (WI):** Explaining 11.18% of the net variance, this factor consists of the four variables: informativeness, resourcefulness, usefulness, and knowledgeability of the website. These items contribute to the information available on the preferred shopping website, therefore titled as web informativeness;
- **Effectiveness of Information Content (EIC):** Items in this factor focussed on the effectiveness of information available on the web portal which is used by online shoppers. The items were: accuracy, recentness, completeness and relevance of information on the website. This factor explained 7.37% of the total variance;
- **Hedonic Shopping Values (HSV):** Items in this factor explain hedonistic values associated with online shopping. With focus on pleasure derived from the shopping experience, the factor comprised of four items: excitement of online shopping, enjoyment during online shopping, enjoyment during online shopping as compared to other activities, and desire to continue shopping. 6.38% of the net variance was explained by this factor;
- **Utilitarian Shopping Values (USV):** The fifth factor comprised of three items: searching for only the required items, buying the needed items and sense of accomplishment on a shopping trip. These items relate to utility of online shopping and this factor explained 5.64% of the total variance.

Cluster Analysis

Cluster Analysis is a technique that can be used to group respondents, such that each of the groups are as homogenous as possible within, and at the same time, as heterogeneous as possible with respect to the other groups (Hair et al., 2010). Factor scores were identified for each of the respondents based on the five factors that characterise the shopping values and website characteristics.

Hierarchical cluster analysis, using Ward's method, was conducted, followed by k-means analysis. K-means clustering technique requires the researcher to specify the number of clusters needed in the solution. The dendogram obtained from hierarchical clustering suggested that could be four clusters in the dataset. Analysis was continued using the non-hierarchical clustering technique (k-means clustering), where the solution (number of clusters) obtained earlier is taken as the input (k), to obtain the final cluster solution. As the hierarchical technique has shown four clusters, clustering was conducted for obtaining four-clustered solution.

The respondents were segmented using Non-hierarchical (k-means) cluster analysis, on the basis of the five factors that have been identified. After examining the output of various levels of clusters and the distances between them, a four-cluster model was concluded, because of clear interpretability of the solution. F value for each cluster indicates that there is a significant difference among all the clusters on all five factors (Lockshin et al., 1997; Orth et al., 2004).

Table 2 shows the solution of cluster analysis. Similarly, Figure 1 represents the clusters formed.

Table 1. Factor analysis

Items	Factor Loading (n = 319)	Cronbach Alpha (α)	% Variance
Factor 1 - Web Entertainment			
Fun derived from browsing the website	0.70	0.90	41.44%
Excitement while browsing the website	0.80		
Imaginativeness of the website	0.72		
Entertainment during browsing of website	0.85		
Attractiveness of the website	0.79		
Factor 2 - Web Informativeness			
Informativeness of the website	0.70	0.88	11.18%
Resourcefulness of the website	0.83		
Usefulness of the website	0.73		
Knowledgeability of the website	0.79		
Factor 3 - Effectiveness of Information Content			
Accuracy of information on the website	0.74	0.88	7.37%
Recentness of information on the website	0.84		
Completeness of information on the website	0.82		
Relevance of information on the website	0.73		
Factor 4 - Hedonic Shopping Values			
Excitement of online shopping	0.66	0.82	6.38%
Enjoyment during online shopping	0.80		
Enjoyment during online shopping as compared to other activities	0.82		
Desire to continue shopping	0.70		
Factor 5 - Utilitarian Shopping Values			
Search for only the required items	0.81	0.68	5.64%
Buying the needed items	0.64		
Sense of accomplishment on shopping trip	0.73		

The demographic description (gender, age, marital status, education level, occupation, family income per month) and frequency of visiting websites per month of the various segments under consideration is shown in Table 3.

Interpretation and Description of Cluster Segments

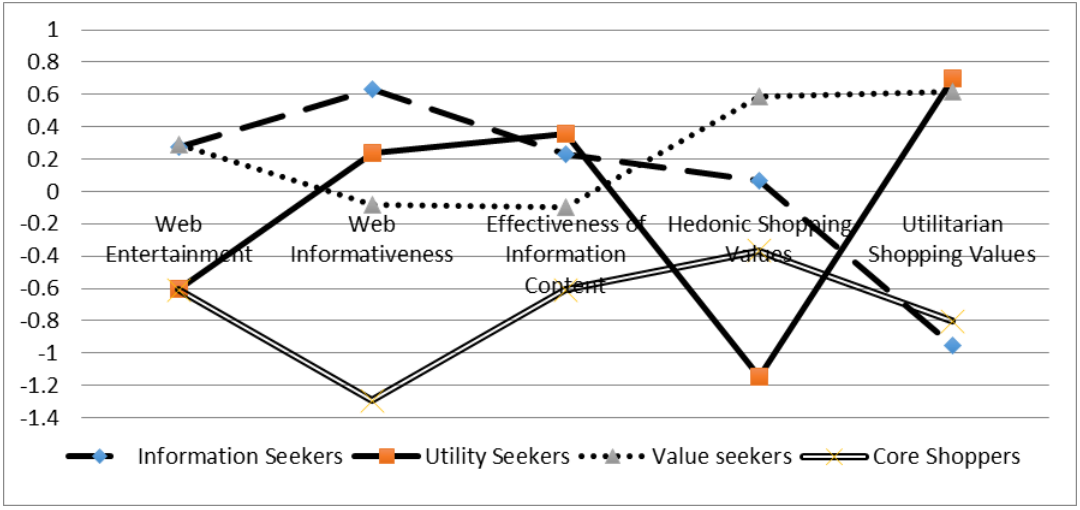
The segments arrived through clustering were explained based on the centroid value of the five factors. A positive value of the centroid shows the significance of the nature of the cluster, whereas a zero value determines that the position is neutral. A negative value of the centroid shows that the factor is not of significance to the respondents within each of the cluster. Following is the description of the clusters.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Non-hierarchical cluster analysis

Website Characteristics and Shopping Values	Cluster Means				F-Value	P <
	Cluster 1	Cluster 2	Cluster 3	Cluster 4		
	Information Seekers	Utility Seekers	Value seekers	Core Shoppers		
Web Entertainment	0.27794	-0.60223	0.28960	-0.61088	21.998	0.000
Web Informativeness	0.62871	0.23558	-0.08175	-1.29354	58.762	0.000
Effectiveness of Information Content	0.22859	0.35482	-0.10050	-0.60835	10.830	0.000
Hedonic Shopping Values	0.06415	-1.14508	0.58969	-0.36547	68.879	0.000
Utilitarian Shopping Values	-0.95117	0.70183	0.61893	-0.80318	148.218	0.000
Cluster Size	88	57	129	45		
Number of respondents (%)	28%	18%	40%	14%		

Figure 1. Profile of clusters



Information Seekers

With 28% of the total respondents, the first cluster has positive centroid on four out the five factors. These factors are – web informativeness (0.62871), web entertainment (0.27794), effectiveness of information content (0.22859) and hedonic shopping values (0.06415). Thus, all the three information related factors had positive centroid values, while hedonic shopping value had the weakest centroid value. Utilitarian shopping value posted a negative centroid in this cluster. Accordingly, informativeness, resourcefulness, usefulness and knowledgeability of information available on e-commerce sites play a very important role for such users. Dominated by males (71.6%), two-third respondents in this clusters reported more than six visits per month.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Cluster composition

		Full Sample	Information Seekers	Utility Seekers	Value Seekers	Core Shoppers
			Cluster 1	Cluster 2	Cluster 3	Cluster 4
Gender	Male	64.9%	71.6%	70.2%	65.9%	42.2%
	Female	35.1%	28.4%	29.8%	34.1%	57.8%
Age (years)	Under 21	2.5%	4.5%	1.8%	1.6%	2.2%
	21-30	89.7%	92.0%	91.2%	88.4%	86.7%
	30-40	7.2%	2.3%	7.0%	9.3%	11.1%
	40-50	0.3%	--	--	0.80%	--
	Above 50	0.3%	1.1%	--	--	--
Marital Status	Unmarried	88.1%	92.0%	94.7%	85.3%	80.0%
	Married	11.9%	8.0%	5.3%	14.7%	20.0%
Education Level	Schooling	0.6%	--	--	1.6%	--
	Graduation	40.1%	51.1%	40.4%	31.8%	42.2%
	Post-graduation	52.4%	44.3%	52.6%	57.4%	53.3%
	Professional qualification	6.9%	4.5%	7.0%	9.3%	4.4%
Occupation	Student	69.0%	77.3%	70.2%	64.3%	64.4%
	Service	23.8%	18.2%	21.1%	25.6%	33.3%
	Self-employed	4.1%	3.4%	7.0%	3.9%	2.2%
	Homemaker	1.3%	--	--	3.1%	--
	Others	1.9%	1.1%	1.8%	3.1%	--
Family income per month (INR)	< 10000	3.1%	2.3%	3.5%	3.3%	4.4%
	10,001 - 25,000	10.4%	15.9%	5.3%	10.3%	6.7%
	25,001 - 40,000	24.3%	20.5%	29.8%	22.7%	28.9%
	> 40,000	62.2%	61.4%	61.4%	63.6%	60.0%
Frequency of visiting website per month	1 time	14.7%	11.4%	22.8%	5.0%	40.0%
	2 - 5 times	58.3%	52.3%	64.9%	62.0%	51.1%
	6 - 10 times	15.0%	14.8%	8.8%	21.0%	6.7%
	> 10 times	11.9%	21.6%	3.5%	11.6%	2.2%

Utility Seekers

The second cluster has positive centroid on utilitarian shopping values which had the highest value of 0.70183, followed by effectiveness of information content (0.35482), and web informativeness (0.23558). Consisting of 18% of the sample, these shoppers give importance to the utility derived from shopping online. The sense of accomplishment derived from online shopping as well as the shopping for the exact needed items play an important role for such buyers. The cluster has highest percentage of unmarried people and eighty-seven percent of the cluster members visited online sites less than five sites.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Value Seekers

Two-fifth of the respondents belong to this cluster. It has positive centroid values for both the shopping values - utilitarian (0.61893) and hedonic (0.58969), and web entertainment (0.28960). Thus, these shoppers seek satisfaction from both these values and are less persuaded by the information content. E-shoppers draw fun, enjoyment and excitement in accomplishing the desired goals of the shopping trip. More than two-third of these respondents had post-graduation and other professional qualifications.

Core Shoppers

This market segment has negative centroid values on all the five factors indicating indifference to predictors of web portal selection. Consisting of least number of respondents (14%), this segment may be considered as 'zone of indifference.' For marketers, it would be difficult to attract using marketing stimuli extending hedonic or utilitarian shopping values and aligning information characteristics with this segment. Forty percent of the respondents reported that they visit e-commerce portals only once a month. It may be presumed that these shoppers may enjoy shopping offline through brick and mortar stores as against online shopping. Fifty-seven percent of the respondents in this cluster were females.

Correspondence Analysis

Identifying and profiling homogenous segments of shoppers is a necessary condition for developing appropriate strategies, but it may not be a sufficient condition. Cluster analysis must be accompanied with further analysis to develop pertinent strategies. The present study has used correspondence analysis to develop insights about the segments that have been identified. This technique is used to analyze and establish relationship between objects and/or variables, which are plotted on a same map on the basis of their association (Hair et al. 2010). In the present case, correspondence analysis has been used to determine a relationship between the four clusters generated and monthly family income. Figure 2 shows the corresponding association between four clusters and income levels.

The first two dimensions explained approximately 75% of the total variance. Dimension 1, explaining around 50% of the variance, is defined between 'information seekers' at one extreme and 'utility seekers' cluster at the other. This dimension represents the level of need for online shopping. Similarly, the 'value seeker' cluster at one extreme and 'core shoppers' at the other extreme describe dimension 2, which explains 25% of the variance.

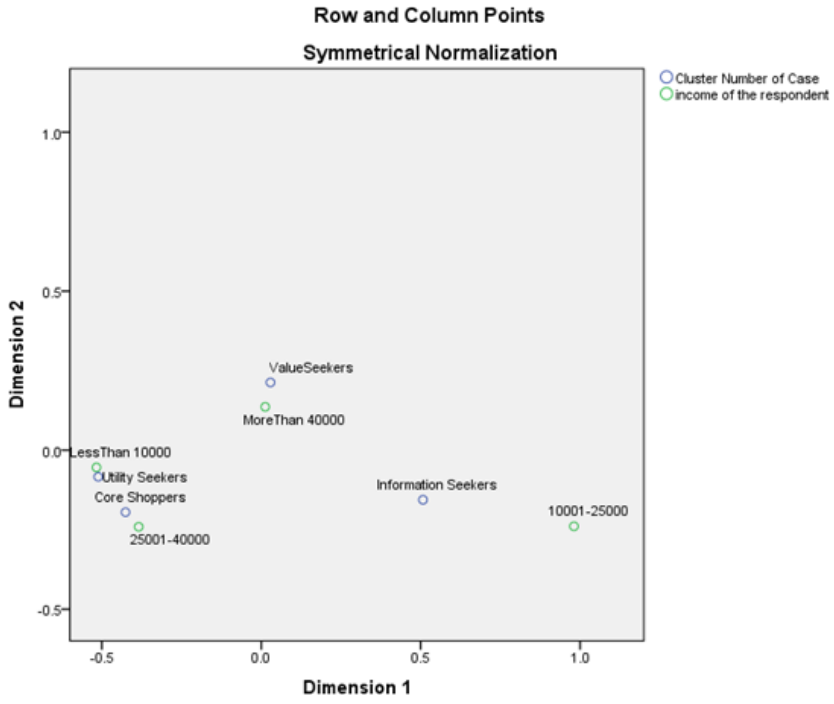
The closer a cluster is to the income level on the graph, the stronger is the perceived identification of that income level with that cluster. Figure 2 shows that shoppers from the income group less than INR 10000 are located close to segment of utility seekers. Low income respondents are usually focused on seeking the products on the web portals that they exactly need and refrain from buying anything that is not needed. Hence, ability to buy the desired products on the web portal provides them with sense of accomplishment. On the other hand, shoppers in the income level of INR 10001-25000 are in the information seekers' segment. These shoppers are frequent visitors of online web portals and are likely to seek new information about various products and offers.

Shoppers with the income group INR 25001-40000 are close to cluster of core shoppers and were found to be less inclined towards any feature of website or any shopping value. Since, more than ninety percent of these shoppers visit web portals with a frequency lesser than other segments, it is assumed

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

that this segment shall prefer offline formats of retail. Finally, the respondents in the highest income group had affinity to be the value seekers. Not only they value usefulness and pertinence of information on web portals, but they also drive fun, pleasure, excitement and enjoyment while shopping and comparing products online.

Figure 2. Correspondence analysis



DISCUSSION

On the basis of predictors of online shopping values and website characteristics, the present study has identified and profiled four significantly diverse clusters – information seekers, utility seekers, value seekers, and core shoppers. Also, with the help of correspondence analysis, it was observed that the four segments were found to be associated with different income groups. The findings of the paper support the idea of using internet as a tool (Vila et al., 2018) for clustering shoppers' based on their shopping motivations.

The characteristic traits of 'value seekers' are similar to the category of discerning shoppers, as has been named and profiled by an earlier study by Jayawardhena et al. (2007), which has grouped shoppers into five different segments - active shoppers, price sensitives, discerning shoppers, brand loyal and convenience oriented. Another study, Mathew (2016) has observed that the online users in India can be segmented into three categories on the basis of attitude – those who comprehend the benefits of online shopping; those who prefer offline mode of shopping; and those who are afraid of shopping online. The second category of users from Mathew's study can be related to 'core shoppers' of the present study who do not frequently visit e-commerce portals and thus might prefer offline shopping. Similarly, the cluster

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of 'core shoppers' identified in this paper was similar to the cluster of 'indifferent shoppers' identified in a recent study by Prashar et al. (2017b).

Reference this research, it is extremely important for online retailers, marketers and web developers to select a specific shoppers' segment(s) that they propose to target. Based upon these, appropriate marketing strategies must be created. From the distinctiveness of the segments arrived, it is observed that different shopping values and web characteristics influence different groups of online shoppers. Some of the shoppers undertake e-shopping owing to its convenience and utility, while many others rely on e-commerce for searching information about products and offers. Similarly, some segments use online shopping as means to derive pleasure and fun, while other segments are not interested in it.

Information seekers are the ones who are attracted to web portals that provide/display reliable information about products/services, and are not interested much into entertainment provided by online shopping. Portals targeting this group can centre their web elements around the theme 'reliability and ease of searching items.' Ensuring accurate images, product specifications and ease of searching the informational cues shall help portals attract such segment and gain loyalty of the same. Students form a large component of the utility seekers, as they focus aggressively on gaining value from online shopping. Portals targeting this segment must focus on offering utilitarian value to such shoppers either by increasing utility of portals or by decreasing prices by offering promotional discounts. Web portals with vast option of products to choose from shall attract such shoppers and help them in closing their shopping trip in one instance.

Value seekers get excited by the monetary and functional benefits of online shopping as well as by the fun they derive while browsing through online portals. They can be targeted with portals which are fun to browse and navigate, and stock the latest gadgets and trendiest items offered at heavy discounts. Enhancing user experience and features like embedded videos, three-dimensional view of items, chat mechanisms and interactivity with and among customers will help attract more users and increased patronization of the segment. Core shoppers generally do not get influenced by either the shopping factors or the web factors. Traditional (offline) retailers must target this segment as these shoppers would prefer shopping offline than online. The retailers can position their stores as the one that provides an 'experience,' which cannot be offered by online portals and offer a different value proposition to consumers. Alternatively, online retailers may enter into brick and mortar format too, albeit on limited basis. This will cater to the needs of such shoppers of experiencing in-person the products and getting solicited by sales personnel at such stores.

CONCLUSION AND MANAGERIAL RECOMMENDATIONS

The results of this study posit the existence of at least three segments of online shoppers on the basis of varied shopping values and characteristics of the web portals. Fourth segment named 'core shoppers' emerged to be in 'zone of indifference,' as the antecedent factors did not show a positive association. It is clearly visible that online shoppers' attitude differs across the four segments. These segments should be catered to with appropriate marketing strategies. This study is of great significance for online retailers and marketers as the online buyers' market has been segmented using two most critical predictors – shopping values (hedonic and utilitarian) and website characteristics (informativeness, effectiveness and entertainment). Unlike this, earlier studies have used factors like internet usage patterns, internet self-efficacy, perceived benefits, perceived risks, website selection factors, lifestyle differences.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

For new e-retailers, the study results can aid in identifying market segments. Marketers can use the segments identified to position their web portals and decide on the marketing strategies accordingly. Illustratively, the e-retailer targeting the first segment of 'information seekers,' must create its brand position around informativeness quotient of web portals. The value proposition must be focussed to provide resourceful, useful and informative details regarding products, offers and desired functional aspects of the website. Effectiveness of information content and entertainment components form support factors for the cluster, and due attention should be given to attractiveness, excitement, accuracy and completeness defining web elements in the portal. The market player seeking to target the segment that has largest number of online buyers must focus on 'value seekers,' which had forty percent of the survey respondents. In this case, e-retailers should attempt to satiate both utilitarian and hedonic shopping values of online shoppers. Buyers' in this segment place lot of emphasis on utilitarian shopping values and achieve a sense of satisfaction by accomplishing the task of shopping their required products through the online shopping portal. Hence, marketers would have to focus on providing hassle-free experience and emphasize on meeting the customer's exact requirements. Brand positioning around quick and convenient shopping experience through superior search mechanisms and easy checkouts must be cemented. Besides utility, these shoppers also want a sense of fun, enjoyment, etc., through the e-shopping experience. E-retailers should incorporate the elements related to hedonism while providing utility through e-portals. Hence, ensuring a good blend of both utilitarian and hedonic values in their websites forms the key strategy for such marketers. To cater to the segment of utility seekers, e-retailers must provide elements that help shoppers derive utility while shopping online. As these shoppers usually seek and buy the required (planned) items only, such marketers must provide suitable navigation system within the site. The navigability must ensure proper data sorting capabilities of the website, leading to ease and convenience of locating, comparing and carting the products. Appropriate and simple categorization of the products is essential requirement for this. These shoppers are usually indifferent to fun and entertainment cues embedded in the online sites. Promotional messages for this segment must focus on the utility aspect of the websites.

The smallest segment identified in this study has been named as 'core shoppers,' who primarily do not have affinity for online shopping. Dominated by female shoppers, the members of this segment presumably enjoy physical shopping as against the virtual online shopping. They are unattached to all the predictive elements of a web portal. Since, the consumers of this cluster display unique attitude, e-retailers must attract those using non-conventional marketing techniques. Online retailers must provide such shoppers with the choice of hybrid shopping experience – encompassing the experience of online as well as traditional offline shopping. Finally, considering the results of corresponding analysis, it is imperative for the retailers to create multiple and exclusive web portals, should they seek to cater to economically diverse segments. In the long run, efforts may be made to graduate shoppers from utility seekers cluster to the segments of information seeker and value seeker.

LIMITATIONS AND FUTURE SCOPE

Like any other cross-sectional study, this research also has few limitations. Understanding of such limitations may build the basis for future research. The data was collected from Indian online shoppers, which is one of the largest growing markets in the world. Hence, any generalization for online shoppers in entirety is constrained. With the ease of access to internet, larger sections from other age groups would

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

also shop online. Therefore, further studies must incorporate data from other demographic segments also. This study being cross-sectional in nature, time factor could have dynamically changed the nature of response. Moreover, the design of preferred website and the choice of website itself is dynamic in nature. Hence a longitudinal study could be conducted to examine the inference of such factors. Future studies can be carried out using experimental design to further validate the findings. This will help in eliminating the possibility of errors owing to self-response bias. Future studies can also focus on looking at the advertising on social media to see if any of the consumers are being influenced to shop online in one platform over another would also be interesting. Studies can cluster shoppers based on the promotions they are being attracted to on various online media.

Chapter 49
Adoption of Online Subscription Beauty Boxes: A Behavioural Reasoning Theory (BRT) Perspective

Brijesh Sivathanu
Symbiosis Centre for Information Technology, Symbiosis International University, Pune, India

ABSTRACT

This article examines the contextual 'reasons for' and 'reasons against' the adoption of beauty box subscription-based online services (BxSOS) in a developing country like India using the behavioral reasoning theory (BRT). This study surveys the female consumers in India to understand the adoption of BxSOS using the unique model of behavioral reasoning theory (BRT). After data collection, the analysis was done using the PLS-SEM technique. The 'reasons for' BxSOS adoption are convenience, ubiquitous, hedonic shopping motivation, social influence and price consciousness and the 'reasons against' are traditional barrier, relative advantage, choice/variety and perceived risk. It is also found that value of "openness to change" significantly influences the 'reasons for' adoption and attitude towards BxSOS whereas it has no impact on the 'reasons against' adoption of BxSOS. This cross-sectional study was conducted with target respondents as female consumers in the Indian context and future research can be conducted in other countries with different cultures and both the genders to generalize the results.

INTRODUCTION

In India, consumers are accustomed to a newspaper or milk subscription on a monthly or yearly basis. These services are savored by the Indian consumers. The similar subscription concept is deployed in the e-commerce sector which is becoming popular in India. There are many online subscription boxes available nowadays, which include beauty products, snacks, jewelry, kid's toys and the monthly sanitary requirements for females. These subscription-based online services (SOS) leverage the e-commerce business model to deliver a customized box of merchandise to the consumer's home on a weekly/

monthly/quarterly/bi-annual basis by charging a subscription fee (Woo, & Ramkumar, 2018). This idea was originally conceptualized in the USA by Birchbox owners - Hayley Barna and Katia Beauchamp, who graduated from Harvard (Griffith, 2015). This subscription-based business model is conducive for the manufacturers to promote their products to the end consumers by providing lower price samples to them. This is a unique and innovative concept emerging in India. BxSOS include the beauty products which are subscribed on a monthly basis and mostly packaged in a colorful bag wrapped with decorative stickers, ribbons and provide the subscriber a sense of luxury and surprise (Chao, 2016; Vanhamme & Dick, 2003).

The research conducted by the Associated Chambers of Commerce & Industry of India (ASSOCHAM) and Majestic Market Research Support Services India Ltd. (MRSS) mention that the market size of the Indian beauty cosmetic and grooming industry is expected to be USD 35 billion by 2035 and current market size is USD 6.5 billion (PTI, 2017). BxSOS business is a subset of cosmetics and grooming industry and BxSoS companies are experiencing a growth of 10-15 percent new subscribers every month in India (Shirodkar, 2017).

There are many subscription-based online beauty and lifestyle boxes in India like Fab-bag, My Envy Box, MSM box, The Nature's Co Beauty Wish Box, Gia Bath & Body Box and Sugar Box. These boxes range from Rs. 300 to Rs. 1000 monthly subscription fees. These online beauty and lifestyle boxes are popular among the young generation in India (Shirodkar, 2017). It is observed that female consumers in the age group of 25-45, having average education and residing in the urban areas are subscribers of these beauty and lifestyle boxes (Shirodkar, 2017). Consumer market research found that females are the major consumers and more involved in buying beauty products online as well as in stores (O'Cass, 2000). There are many challenges faced by BxSOS companies in Asia like the market is niche and customers have an expectation of free samples (Tay, 2016). In Asian countries like Singapore, China, Korea, Taiwan and now in India, BxSOS business is flooded with competitors as there exists a huge market potential for beauty box companies in Asia (Tay, 2016).

In this paper, the behavioural reasoning theory, which is a novel consumer behaviour model, was used to study the antecedents of consumer's adoption of BxSOS in the context of a developing country like India. There exists only one prior study in the context of a developed economy, discussing the fashion and beauty SOS adoption by American consumers (Woo, & Ramkumar, 2018). The extant literature mainly focuses on factors for adoption of online shopping (Ho & Chen, 2014; Cheema et al., 2013; Kim et al., 2014; Chen & Teng, 2013; Celik, 2016; Pascual-Miguel, Agudo-Peregrina and Chaparro-Peláez, 2015). However, there are few studies which explain the resistance to adoption of online shopping (Lian & Yen, 2014; Rahman, Khan, & Iqbal, 2018). The unique feature of this study is that it highlights both the context-specific factors 'for' adoption and resistance factors of BxSOS in a single framework.

BxSOS is a nascent concept in the context of a developing country like India. There is no study in India and other developing countries to examine the adoption of BxSOS. The success of such a novel concept ultimately lies in its acceptance among the consumers. Hence it is important to study the adoption of these BxSOS among the female consumers in a country like India. This exploratory study was conducted to understand the adoption factors and bottlenecks of online subscription beauty boxes. Hence the following research question is formed.

RQ: What are the adoption factors and barriers to the BxSOS using the BRT model.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

LITERATURE REVIEW

Underpinning Theories and Models of Adoption Behaviour

The adoption of BxSOS can be studied using the Technology acceptance model (Davis, 1989); Unified theory of acceptance and use of technology (Venkatesh et al., 2003); Theory of reasoned action (Fishbein & Ajzen, 1975), theory of planned behavior (Ajzen, 1991) and UTAUT 2 (Venkatesh et al., 2012). The BxSOS is considered an innovation in e-commerce which can be also studied with the Diffusion of Innovation Theory (Rogers E. M., 1995). These models mainly focus on the adoption factors and there is no study discussing BxSOS adoption using the above models. There exist a number of prior studies which explain the adoption of online shopping using - TAM (Ho & Chen, 2014; Chen & Teng, 2013); IDT (Gong et al., 2012); UTAUT (Pavlou, 2003; Celik, 2016); UTAUT2 (Pascual-Miguel, Agudo-Peregrina, and Chaparro-Peláez, 2015) and UTAUT & IRT (Lian & Yen, 2014).

The vital predictors of adoption of online shopping are 'perceived ease of use' and 'perceived usefulness' (Ho & Chen, 2014; Hernandez, Jimenez, & Martin, 2009), Social Influence (Ho & Chen, 2014; Venkatesh et al., 2003; Weisberg et al., 2011), Hedonic Motivation (Davis, Lang, & San Diego, 2014; Hsu, Chuan-Chuan Lin, & Chiang, 2013), choice and variety (Srinivasan, Anderson, & Ponnavolu, 2002), Convenience (Khare et al., 2012; Wang et al., 2008), Trust (Ho and Chen, 2014; Jiang, & Jones, 2014) and Enjoyment (Kim et al., 2013; Hsu et al., 2012; Chen and Teng, 2013).

Innovation Resistance Theory

The above technology adoption models and innovation diffusion models focused on the predictors of adoption of technology and there was less importance given to the resistance to innovation by the consumers. There are some studies that highlighted the negative factors (Ram, 1987; Kleijnen, Lee & Wetzels, 2009). Innovation resistance theory proposed the factors responsible for the resistance to the innovation by the consumers (Ram, 1987). An innovation or change develops a conflict between innovation and tradition which leads to a barrier or resistance to the innovation (Ram & Sheth, 1989). As per (Ram & Sheth, 1989), there are two aspects of a barrier- psychological and functional. Functional include value, usage, and risk barrier whereas psychological has an image and traditional barriers. As per (Lian & Yen, 2014), in online shopping, younger and older adults have value barrier, whereas older adults have more barriers like traditional barrier and risk barrier. The extant studies found that privacy and security concerns (Wu and Wang, 2005; Thakur and Srivastava, 2013), perceived risk (Kim and Peterson, 2017; Lamberton and Stephen, 2016) and consumer anxiety (Celik, 2016) negatively influence the adoption of online shopping. The relative advantage and perceived risk are barriers to online shopping behavior of consumers (Corbitt et al., 2003; Chang, & Chen, 2008; Gupta, & Arora, 2017b).

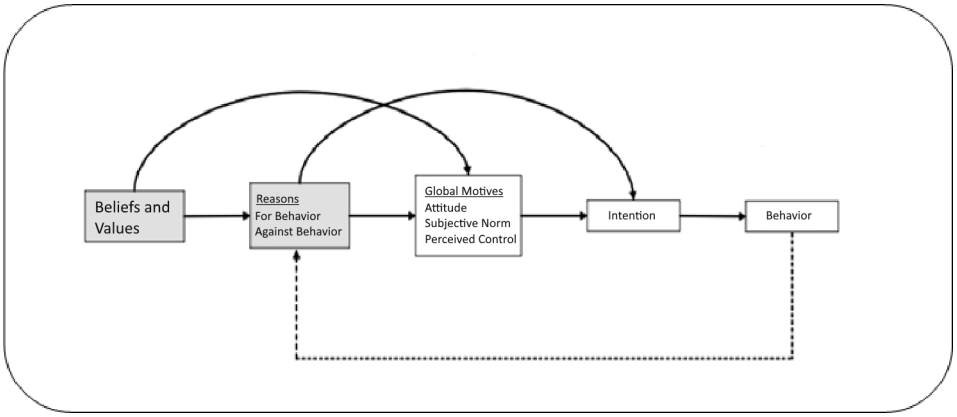
Behavioral Reasoning Theory

There are prior studies that discuss the online shopping adoption determinants and barrier determinants; however, there is no study which examines both of these factors in a single framework. The factors for adoption and barriers to adoption are not necessarily logically opposite to each other as mentioned in the social psychology studies (Westaby et al., 2010). The single framework, which is BRT - Behavioral Reasoning Theory (Westaby, 2005b) can be used to examine the relative influence of adoption and resis-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

tance factors. The reason theory (Westaby & Fishbein, 1996) and decision-making theory (Pennington and Hastie, 1988) are in line with these; however, BRT pointed out that context-specific reasons serve as important linkages between people's belief, intention, behavior and global motives (Westaby, 2005b). As suggested by Westaby (2005b), Reasons means "specific subjective factors people use to explain their anticipated behavior and can be conceptualized as anticipated reasons, concurrent reasons and post hoc reasons". Reasons are conceptually different from beliefs. In BRT, (Westaby, 2005b) there are two facets considered - 'reasons for' and 'reasons against' to carry out a particular behavior. These reasons are framed clearly and considered as cost/benefit, facilitator /constraints and pros /cons (Westaby, 2005a). The BRT Model is as shown in Figure 1.

Figure 1. Behavioral reasoning theory (Westaby, 2005b)



The BRT is used to study the innovation adoption in some of the extant studies (Claudy et al., 2015; Chatzidakis and Lee, 2013; Claudy, Peterson and O'Driscoll, 2013). These studies justify the single framework of BRT which can be used to study the determinants of adoption and its barriers. The BRT discusses the consumer's reasons which influence the consumer's cognitive process of adoption of the innovation (Gupta, & Arora, 2017a). The study on mobile shopping by (Gupta, & Arora, 2017a) found that 'reasons for' are price saving, choice/variety and convenience, whereas 'reasons against' are self-efficacy, consumer anxiety and relative advantage. The study on mobile banking mentions that 'reasons for' adoption such as convenience and ubiquitous were adopted from extant BRT studies and traditional barrier is an important 'reason against' (Gupta, &Arora, 2017b).

RESEARCH OBJECTIVES

This study highlights the adoption of BxSOS and it has the following objectives:

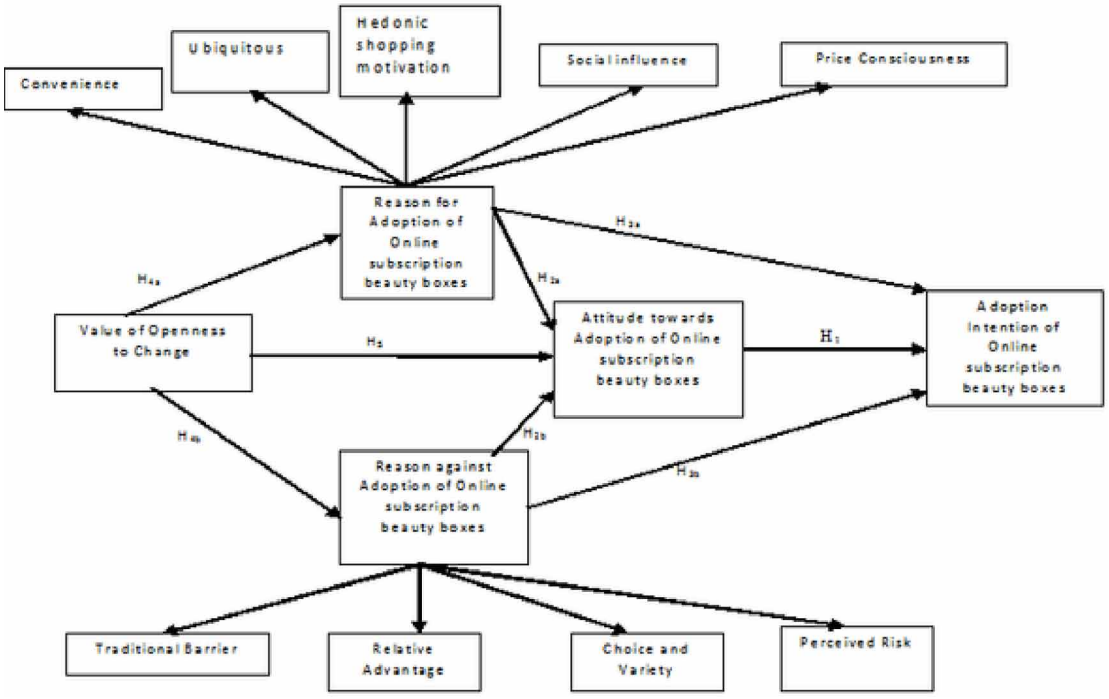
1. To develop a theoretical model utilizing the Behavioral reasoning theory to understand the adoption of BxSOS;
2. To empirically validate the theoretical framework.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

THEORETICAL BACKGROUND AND HYPOTHESES DEVELOPMENT

The conceptual framework is provided in Figure 2. The BRT theory discusses that behavior can be predicted by the intentions of the consumers. As per BRT (Westaby, 2005b), global motives (attitude) influence the intention of the consumers, reasons ('for' and 'against') influence attitude and reasons also predict the intention. These reasons 'for' and 'against' are influenced by the values and beliefs of the consumer. The hypotheses are explained in the following sections.

Figure 2. Conceptual framework



Attitudes and Adoption Intentions

As per Eagly and Chaiken (1993), attitude means, "a psychological tendency that is expressed by evaluating a particular entity with some degree of favor or disfavor". The extant literature mentioned that attitude influences the behavior (Davis 1989; Fishbein and Ajzen, 1975; Westaby, 2005; Mansour et al., 2016). The earlier studies confirmed that attitude influences the behavioral intention in the context of mobile banking (Gupta, & Arora, 2017b), Mobile shopping (Wu and Wang, 2005; Gupta, & Arora, 2017a) and innovation adoption (Claudy, Garcia, & O'Driscoll, 2015). The BxSOS is an innovation in the e-commerce space, so the following hypothesis is considered:

H_1: Consumers' attitudes towards online subscription of beauty boxes positively influence their adoption intentions.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reasons and Attitudes

BRT has a distinctive aspect as it discusses the context-specific reasons predicting the attitude towards the certain behavior and intentions (Westaby, 2005b). As per BRT (Westaby, 2005b), Reasons mean "The specific subjective factors people use to explain their anticipated behavior" and serve as an important predictor of global motives (i.e. attitudes) and intentions". The reasons have two dimensions are per BRT a) Reason for b) Reason Against. The belief and reasons are differentiated in terms of temporal orientation in memory (Westaby, 2005b). The implication of this is that a consumer might have a belief about the outcome of adapting to an innovation, but might not result in adoption (Claudy et al., 2015). In the context of mobile shopping, beliefs would reflect people's opinion about m-banking in general, whereas reasons for/against adoption would constitute specific factors that may influence adoption. (Gupta, & Arora, 2017a; Westaby, 2005b) argue that reasons demonstrate incremental predictive validity as compared to the traditional belief concept. As per (Claudy et al., 2015), though consumers have a favorable belief in adoption still they might resist adoption due to 'reasons against' a particular behavior. Hence it is hypothesized that:

H_{2a}: Consumers' 'reason for' online subscription of beauty boxes will positively influence their attitude towards BxSOS adoption.

H_{2b}: Consumers' 'reason against' online subscription of beauty boxes will negatively influence their attitude towards BxSOS adoption.

Reasons and Intentions

As per (Westaby, 2005b) consumers are more comfortable when they have enough reasons to defend or justify their expected actions. BRT explains that reasons influence the behavioral intention of the individual (Westaby, 2005). BRT mentions that reasons contribute to the behavioral intention of the individual. The extant literature on technology adoption mentioned that context-specific factors influence the adoption intentions which include the adoption models such as the UTAUT (Venkatesh et al., 2003) and TAM (Davis, 1989). Intentions are strong predictors of consumer behavior (Ajzen, 1991). With reference to the BRT theory, it is necessary to study the reasons affecting the adoption of BxSOS, so following hypotheses were formed:

H_{3a}: Consumers' 'reason for' online subscription of beauty boxes will positively influence their intention towards BxSOS adoption.

H_{3b}: Consumers' 'reason against' online subscription of beauty boxes will negatively influence their intention towards BxSOS adoption.

Values and Reasons

Openness to change relates to a value which motivates individuals to pursue their own emotional and intellectual interest in uncertain directions (Schwartz, 1992). As per Raajpoot and Sharma, (2006) people who are ready for openness to change value accept the changes and adoption of new products (Wang et al., 2008). The BxSOS is an innovative concept and a new service/product in the market; hence open-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ness to change value can be applied to this research. The construct for "Openness to change" values is adopted from earlier research (Claudy et al., 2015; Gupta, & Arora, 2017a; Wang et al., 2008).

The expectancy-value theory mentions that the belief an individual holds about the expected outcome and its outcome value affect the process of motivation (Vroom, 1964; Fishbein & Ajzen, 1975). The theory of Explained behavior (Pennington and Hastie, 1988) and BRT (Westaby, 2005b) proposed that values affect the reasoning of adoption. In previous innovation studies, it was found that consumers are expected to adopt new innovations when they feel that it is compatible with their personal values (Claudy et al., 2013). With reference to mobile shopping, it was found that value can have an effect on consumer adoption decision (Gupta, & Arora, 2017a):

H_{4a}: Consumers' values will (positively / negatively) influence their 'reason for' online subscription of beauty boxes.

H_{4b}: Consumers' values will (positively /negatively) influence their 'reason against' online subscription of beauty boxes.

Values and Attitudes

Values and beliefs can have a direct impact on attitude as sometimes reasons may not be fully activated, so consumers may depend upon heuristics motives (Kahneman et al., 1982; Westaby, 2005b). The earlier studies on consumer behavior discuss the importance of value in the purchase decision of the consumer (Kahle et al., 1986; Shareef, Kumar, & Kumar, 2008). The reasoning for adoption is not expected to occur in isolation; however, its deep-rooted values influence the adoption of innovation (Westaby 2005, p. 102). It is found that values positively affect the attitude (Gupta, & Arora, 2017). With this, the hypothesis is postulated as:

H_5: Consumers' values will (positively/negatively) influence their attitude towards online subscription of beauty boxes.

In total, the Behavioral reasoning theory serves as an interesting theoretical framework providing a better explanatory power to study the adoption of BxSOS. This framework facilitates the study of the adoption of BxSOS by studying value, attitude, 'reason for' and 'reason against' in a single framework.

Reasons Extraction and Measures

Online shopping is common in India; however, BxSOS is an emerging concept in India. It will be interesting to understand the 'reason for' and 'reason against' adoption of BxSOS. The target consumers of beauty boxes are females in the urban areas (Shirodkar, 2017), so this study designed and tested the hypotheses by surveying the female consumers. It was observed that females tend to shop more online than males (Li et al., 1999). The female consumers who had an online shopping experience were considered for this study. The researcher ensured that female consumers who had already subscribed to BxSOS were not considered for the survey as this study aims to understand the behavioral intention to adopt BxSOS.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reason Extraction

This study aims to understand the 'reason for' and 'reason against' adoption of BxSOS. To elicit the context-specific 'reason for' and 'reason against' adoption of BxSOS, qualitative research was conducted. This method was considered with reference to previous BRT studies (Westaby, 2005b; Claudy and Peterson, 2014; Claudy et al., 2013, 2015; Westaby et al., 2010; Gupta, & Arora, 2017a). These reasons were discussed with five subject matter experts and subsequently finalized. After this, 30 face-to-face semi-structured interviews were conducted with female consumers who buy beauty products online. The researcher ensured that these female consumers had not purchased BxSOS, but were aware of the BxSOS concept. For these semi-structured interviews, the participants were provided with a list of statements "The reasons why I will subscribe to BxSOS." The reasons listed were: - Convenience – BxSOS is convenient to my need; Ubiquitous – I can subscribe it anytime and anywhere; Hedonic shopping motivation – it is fun-filled and enjoyable experience; Social influence – My friends and colleagues subscribed to it, and Price consciousness – It is fairly priced. The participants were requested to point out on a four-point scale, the extent to which each of the statement could be the 'reason for' adoption of subscription-based beauty boxes. The calibration of the scale was performed by following Westaby (2005b) and Oh and Teo (2010), with 0 = "not a reason," 1 = "a somewhat influential reason," 2 = "influential reason" and 3 = "very influential reason". Using the procedures similar to Richins and Dawson (1992), the researcher transcribed the interviews and elicited the most frequently mentioned reasons. Based on this, the five 'reasons for' adoption of BxSOS were identified as - Convenience, Ubiquitous, Hedonic shopping motivation, Social influence and Price consciousness. It was found that the following reasons - Convenience (mean= 2.89, sd =0.90), Ubiquitous (mean=2.71, sd =0.88), Hedonic shopping motivation (mean=2.59, sd =0.84), social influence (mean=2.45, sd =0.82) and price consciousness (mean=2.36, sd =0.78) were the 'reasons for' adoption.

The same procedure was used to find out 'reason against' adoption of BxSOS. For these semi-structured interviews, the participants were provided with a list of reasons prefaced with the statement – Reason Why I will not subscribe to online beauty boxes. The 'reasons against' listed were Traditional Barrier - I like purchasing beauty products from retail shops; Choice and Variety – BxSOS has limited choice and variety of beauty products; Perceived Risk – It is risky as it will deliver beauty products below my expectation; Relative Advantage - I don't find any reason to subscribe BxSOS. Participants were asked to indicate, on a four-point scale (0-3), the extent to which each of the statement could be the 'reason against' adoption of online subscription of beauty boxes. The calibration of the scale was performed following Westaby (2005b) and Oh and Teo (2010), with 0 for "not a reason," 1 for "a somewhat influential reason," 2 for "influential reason" and 3 for "very influential reason." With these, four 'reasons against' adoption of subscription of beauty boxes were identified as - Traditional barrier, Choice & Variety, Perceived risk and Relative advantage. It was found that following 'reasons against' adoption were - Traditional barrier (mean=2.69, sd =0.84), Choice / Variety (mean=2.42, sd =0.72), Perceived risk (mean=2.36, sd =0.78) and Relative Advantage (mean=2.16, sd =0.69).

Table 1. Operationalization of constructs

Main Construct:	Type		Indicator/item	Reference
Reasons for				
Convenience	Reflective	CN1	Online subscription beauty boxes are convenient to my beauty needs.	Claudy et al., 2015; Westaby, 2005b; Westaby et al., 2010; Gupta, & Arora, 2017a
		CN2	Online subscription beauty boxes save time and effort of purchasing beauty products.	
		CN3	Online subscription beauty boxes are the simplest way of buying my beauty products.	
Ubiquitous	Reflective	UQ1	Online subscription beauty boxes help to know new beauty products in the market.	Claudy et al., 2015; Westaby, 2005b; Westaby et al., 2010; Gupta, & Arora, 2017a
		UQ2	Online subscription beauty boxes keep me updated about beauty products all the time.	
		UQ3	Online subscription of beauty boxes can be done anywhere in the city.	
Hedonic Shopping Motives	Reflective	HS1	I feel the online subscription of beauty boxes is an exciting idea.	Khare, & Rakesh, 2011; Davis, Lang, & San Diego, 2014
		HS2	Online subscription of beauty boxes is a fun-filled enjoyable experience.	
		HS3	I like the surprise element associated with the online subscription of beauty box.	
Social Influence	Reflective	SF1	People who influence my behavior think that I should use online subscription beauty boxes.	Venkatesh et al., 2003
		SF2	I would shop online subscription beauty boxes because of the proportion of my friends, who also do the same.	
		SF3	People who are important to me think that I should purchase online subscription beauty boxes.	
Price Consciousness	Reflective	PS1	I am willing to purchase online subscription beauty boxes as they are fairly priced.	Alford, & Biswas, 2002
		PS2	I would always shop an online subscription box which is priced lower.	
		PS3	The money saved by finding lower prices of online subscription of beauty boxes is usually worth the time and effort.	
Reasons against				
Tradition barrier	Reflective	TB1	I enjoy purchasing beauty products from the retail shop as it is nice to do so.	Claudy et al., 2015; Westaby, 2005b; Westaby et al., 2010; Gupta, & Arora, 2017a
		TB2	I only purchase my beauty products from the retail shop as per my choice.	
		TB3	I am happy with my current way of purchasing beauty products from the retail shop.	
Choice / Variety	Reflective	CV1	Online subscription beauty boxes do not provide a “one-stop shop” for my beauty shopping	Srinivasan, Anderson, & Ponnavolu, 2002
		CV2	Online subscription beauty boxes do not satisfy the majority of my beauty needs.	
		CV3	The choice of the products in online subscription beauty boxes is limited.	
		CV4	Online subscription of beauty boxes do not have a wide selection of products to choose from.	

continues on following page

Table 1. Continued

Main Construct:	Type		Indicator/item	Reference
Relative advantage	Reflective	RA1	Online subscription of beauty boxes is not easier than buying beauty product by other means.	Claudy et al., 2015; Westaby, 2005b; Westaby et al., 2010; Gupta & Arora, 2017
		RA2	Online subscription of beauty boxes takes more time and efforts and does not provide all kinds of beauty products.	
		RA3	Online subscription beauty boxes are not more valuable to me than other ways of purchase of beauty product.	
Perceived Risk	Reflective	PR1	I feel that the online subscription of beauty boxes is risky because the beauty boxes delivered may fail to meet my expectations.	Corbitt et al., 2003; Gupta & Arora, 2017
		PR2	I believe that online subscription of beauty boxes is risky as it may delivery inferior beauty products	
		PR3	I feel online subscription of beauty boxes is risky as it may lead to the financial loss due to advance payment of subscription	
		PR4	I believe that online subscription beauty boxes may not deliver products which will fit as per my personal beauty needs.	
Value of openness to change	Reflective	VO1	I every time look for new things to do and surprises.	Claudy et al., 2015; Wang et al., 2008
		VO2	I like to experience new things.	
		VO3	I am open to new experiences.	
Attitude	Reflective	AT1	Generally speaking, Online subscription of beauty boxes is a great idea.	Claudy et al., 2015; Wang et al., 2008; Gupta, & Arora, 2017
		AT2	Online subscription of beauty boxes offers a lot of benefits.	
		AT3	Online subscription of beauty boxes in the near future will add a lot of value.	
Adoption Intention	Reflective	AD1	I will use online subscription beauty boxes	Fishbein & Ajzen 1975; Gupta, & Arora, 2017a
		AD2	I can see myself using online subscription beauty boxes	
		AD3	I intend to use online subscription beauty boxes

Measures

The measures of this study were adopted from the extant literature of BRT (Westaby, 2005b; Westaby et al., 2010; Claudy et al., 2015; Gupta, A., & Arora, N., 2017a) and demonstrated in Table 1. All the constructs were measured on a five-point Likert scale (1 = "strongly disagree" and 5 = "strongly agree"). With reference to the previous research (Fishbein and Ajzen, 1975; Gupta, & Arora, 2017a), the adoption intention and attitude are measured.

RESEARCH METHODOLOGY

Research Instrument Design

This study used the research instrument from the earlier studies conducted with reference to behavioral reasoning theory (BRT) (Westaby, 2005b) to understand the adoption of BxSOS. This study mainly adopted the scales from the previous studies (Claudy et al., 2015; Westaby, 2005b, Westaby et al., 2010, Wang et al., 2008; Gupta, & Arora, 2017a) regarding the BRT model. As per Fornell and Larcker, 1981, it is imperative to establish the validity of the constructs and reliability of the scale, so this study verified the scale for each of the above constructs.

SAMPLING AND DATA COLLECTION

Pilot Study

Before the data collection process, to establish face validity, five subject matter experts were identified and exposed to the overall scope and objectives of the study. After incorporating the suggestion and feedback regarding the suitability of all constructs, the questionnaire for the pilot test was finalized. To measure the constructs operationalized in this study, a five-point Likert scale was used. To assess the research instrument's validity and reliability a pilot test was conducted. The researcher carried out a pilot test (N=155) among the female respondents in malls, beauty parlors and public places. The target female respondents selected for this study were consumers who were shopping beauty products online and the researcher ensured that the respondents had not purchased BxSOS; however, they were aware of BxSOS. After data collection, the data was analyzed using PLS-SEM. The main data collection was carried out after satisfactory results were obtained in the pilot test. To evaluate the reliability and internal consistency of the data, Cronbach alpha was used (Nunnally, 1978).

The operationalized constructs used in this study are as shown in Table 1.

Primary Data Collection

The PLS path modeling technique has the benefit that it is not affected by small sample size. To ascertain the adequate sample size required for this study, the thumb rule (Gefen et al., 2000) was considered. For assessing the required sample size, ten times the number of items of the biggest construct in the research model was used (Construct- 'Reasons for' with 15 items). Hence, the required sample size for

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

this study is 150 respondents. The primary data collection was done using a structured questionnaire, which was administered to the respondents. The female respondents were considered for this study as most of the BxSOS subscribers were females as per the beauty box company's marketers. The target female respondents selected for this study were consumers who were shopping beauty products online and the researcher ensured that the respondents had not purchased BxSOS; however, they were aware of BxSOS. The convenience sampling method was deployed for this study in Mumbai and Pune city along with its suburbs for a period of three months from August to October 2017. These female consumers were surveyed in retail shopping malls, beauty product outlets, cosmetic shops and beauty parlors by requesting them to fill up the questionnaire or requested to respond to the questionnaire in person. The target respondents chosen for this study were appropriate as these respondents were females having average education, who reside in the urban areas, possess sizable disposable income and had not subscribed to BxSOS; but, were aware of BxSOS. The total female consumers surveyed for this study were 1690 out of which 654 responses were overall found fit for analysis. The demographic details are provided in Table 2.

Non-Response Bias

In survey methods, non-response bias is considered a serious concern, as it limits the generalization of the findings (Michie and Marteau, 1999). Hence, it needs to be addressed by the researchers (Lewis et al., 2013). Hence, appropriate steps were taken by the researcher to ensure that non-response is not an issue for this study. This was done by dividing the data into two data sets (early respondents vs. late respondents) by performing the wave analysis. The comparison of the early and late wave responses was done to test for non-response bias (Amstrong and Overtons, 1977). The t-test analysis showed no significant differences (p=0.41) between the early wave (374) and late wave (280) groups, indicating that non-response bias does not affect this study. Finally, 654 responses were found fit for analysis in all respects.

The demographic profile of the respondents is shown in Table 2.

Table 2. Respondent demographic profile (N=654)

Demographic	Characteristics	Frequency	Percentage
Age	21-30	239	37
	31-40	238	36
	41-50	149	23
	51 and above	28	4
Education	Diploma	98	15
	Graduate Degree	257	39
	Post Graduate/ Masters	299	46
Shopping of beauty products online (not subscribed to BxSOS)	Less Than 3 months	62	10
	3 to 6 months	201	31
	6 to 12 months	258	39
	More than year	133	20

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Data Analysis

Common Method Bias

Survey-based method for data collection was used to test the research hypothesis in this work. When the response data is collected from multiple sources, it may suffer from the risk of the presence of common method bias (Mackenzie and Podsakoff, 2012; Podsakoff et al. 2003; Podsakoff and Organ, 1986). The researcher conducted the single factor Harman test (Podsakoff and Organ, 1986) to examine the occurrence of common method bias in this work. On performing the analysis of the research framework, the results from this test show that 18.79 percent of the variance is explained by a single factor which is less than 50%. This proves that common method bias is not a concern in this research.

With reference to the above criteria, there is sufficient evidence of validity and reliability in the measures of this study.

PLS-SEM

As the PLS-SEM path modeling technique has the capability to represent the latent variable constructs in this work, it is used to test the conceptual research framework and assess the causal relationship between the indicators and latent constructs (Gudergan et al., 2008). When the objective of the research is to extend the existing theory (Hair et al., 2011), PLS-SEM is preferred over maximum likelihood (MLE) as it is a flexible technique to model the research constructs (Henseler, 2010). So, the SmartPLS software (Ringle et al., 2005) was used for data analysis.

Measurement Model

The multi-item reflective constructs in the hypothesized framework were used to calculate the measurement properties in the final measurement model. The indicator's factor loadings were more than 0.5 (Hair et al, 2006). The reliability of the measure was established as the Cronbach alpha for all the constructs were more than 0.7. This shows the high internal consistency of all the research constructs used (Nunnally, 1978).

The outer item loadings and composite reliability (CR) was checked to evaluate the reflective measurement items. To check the convergent validity, the average variance extracted (AVE) was calculated. The outer loadings for all the items were more than the minimum threshold value of 0.6 and all the research constructs show high levels of internal consistency/ reliability shown by the CR values as displayed in Table 3. The convergent validity for all the constructs is confirmed as the AVE values are more than the minimum threshold value of 0.5 (Hair et al., 2006).

The outer loadings for all the items were more than the minimum threshold value of 0.6 and all the research constructs show high levels of internal consistency/ reliability shown by the Composite Reliability (CR) values as displayed in Table 3. The convergent validity for all the constructs is confirmed as the AVE values are more than the minimum threshold value of 0.5 (Hair et al, 2006).

a. Average variance extracted (AVE)=(summation of the square of the factor loadings)/{(summation of the square of the factor loadings)+(Summation of the error variance)}
b. Composite reliability (CR)=(Square of the summation of the factor loadings)/{(square of the summation of the factor loadings)+(Square of the summation of the error variance)}

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The assessment of the discriminant validity of the research constructs was done using the Fornell and Larcker (1981) criterion. The discriminant validity of the constructs is verified by the off-diagonal values in Table 4 which shows the correlation between the latent constructs. The comparison of the construct inter-correlations with average variance extracted (AVE) was done to prove the discriminant validity as shown in Table 4. Discriminant validity was ascertained as the shared variance values were less than the corresponding AVE (Fornell & Larcker, 1981). Hence discriminant validity between the research constructs were verified.

Table 4. Discriminant validity (Fornell-Larcker criteria)

Structural Model

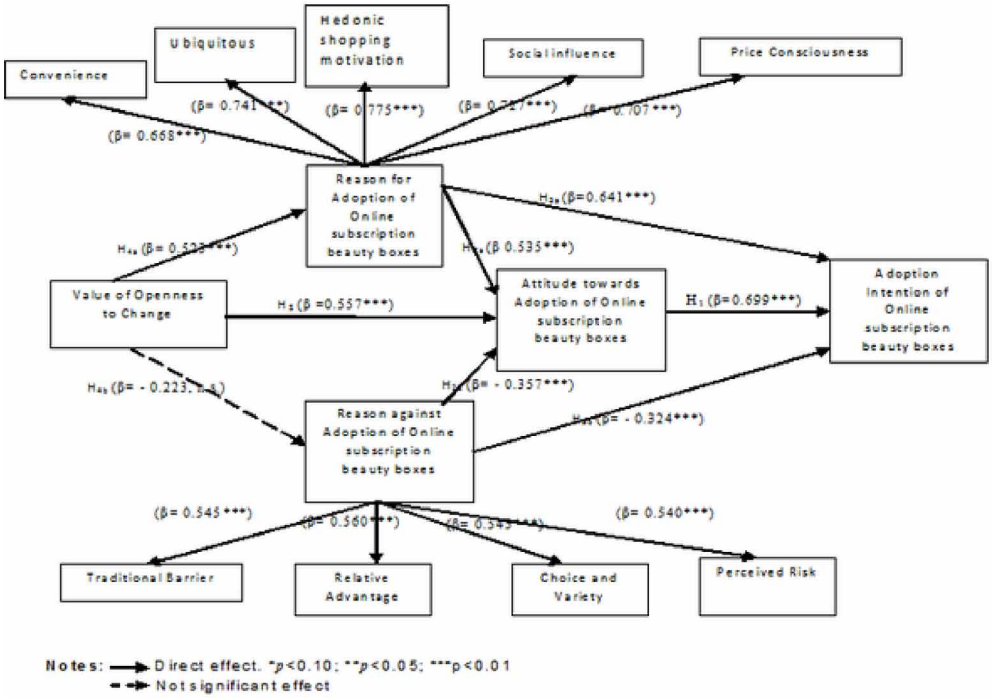
After the evaluation of the measurement model, it was found to be reliable and valid. Hence the path analysis was carried out to assess the structural model relationships among the constructs using PLS-SEM (Figure 3) by calculating the path coefficients and its significance as shown in Table 5. The designated second order constructs were tested by the researcher using the repeated indicators approach (Lohmüller, 1988). For valuing the higher order constructs (Wilson and Henseler, 2007), the popular approach using the hierarchal the component model (Chin et al., 2003) was carried out by the author. It implies the hypothesized relationships between the various research constructs, the assessment of the level of R^2 values and predictive relevance Q^2 (Table 6).

RESULTS

The R^2 values of and the predictive relevance Q^2 of the endogenous latent constructs- attitude towards adoption, 'reasons for' adoption, 'reasons against' adoption and adoption intention of online subscription beauty boxes are as shown in Table 6.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Results of PLS-SEM model



The results reveal that reasons are context specific and are salient predictors of adoption of online subscription beauty boxes. The attitude significantly influences the adoption intention towards the online subscription of beauty boxes (H_1: β=0.699, $p < 0.01$). It confirms that consumer's attitude towards BxSOS has an influence on adoption intention towards BxSOS. It was found that 'reasons for' adoption has a positive effect on attitude of consumers (H_{2a}: β=0.535, $p < 0.01$) and also on adoption intention (H_{3a}: β=0.641, $p < 0.01$). It confirms that 'reason for' adoption positively affect the attitude and adoption intention of female consumers towards the adoption of BxSOS.

The 'reason against' adoption negatively affects the adoption intention (H_{3b}: β= -0.324, $p<0.01$) and attitude (H_{2b}: β= -0.357, $p < 0.01$) towards adoption of BxSOS. With reference to the above, the 'reason for' adoption of BxSOS has more influence on attitude and adoption intention than 'reason against' adoption.

Openness to change influences the 'reason for' adoption (H_{4a}: β=0.523, $p < 0.01$) and does not influence 'reasons against' adoption (H_{4b}: β= − 0.223, not significant). As the female consumers are open to change, they are ready to experiment with the new beauty products and free gifts of beauty products in the subscription boxes, so it does not affect the 'reason against'. Value of openness to change influences the attitude (H_5: β=0.557, $p < 0.01$) towards the BxSOS. Female consumers have openness to change which affects the 'reason for' adoption and forms a positive attitude towards the adoption of BxSoS.

Adoption intention towards online subscription beauty boxes	0.646	0.322
Reasons for the adoption of online subscription beauty boxes	0.734	0.448
Reasons against adoption of online subscription beauty boxes	0.644	0.308

a. Assessment of predictive relevance (Q^2); Value Effect Size; 0.02 Small; 0.15 Medium; 0.35 Large

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

All second order constructs of reasoning are significant. It is found that Convenience (β =0.668, $p < 0.01$), Ubiquitous (β =0.741, $p < 0.01$), Hedonic Shopping Motivation (β =0.775, $p < 0.01$), Social Influence (β =0.727, $p < 0.01$) and Price Consciousness (β =0.707, $p < 0.01$) are the 'reasons for' adoption of BxSOS. It is found that ordering online subscription boxes is easy as it can be ordered from anywhere & anytime, so convenience and ubiquitous are 'reasons for' adoption of online subscription beauty boxes. The female consumers enjoy surprise branded products every month in the beauty boxes which are new in the market, so hedonic shopping motivation is an important factor for adoption. Generally, females discuss and recommend the beauty products to their peers and since the online subscription is a nascent concept in India, so social influence is also an important factor for adoption. Working females have sufficient amount of money at their disposal. Online subscription box contains one core beauty product, which itself costs higher than the subscription value along with the other testers in the beauty box, so it is affordable to the female consumers. Hence, Price consciousness is also one of the important factors for adoption of BxSOS.

It is found that the Traditional barrier (β =0.565, $p < 0.01$), Choice and Variety (β =0.545, $p < 0.01$), Relative Advantage (β =0.560, $p < 0.01$) and Perceived Risk (β =0.540, $p < 0.01$) are 'reason against' adoption of online subscription beauty boxes. The traditional barrier exists, as females also prefer to go to beauty product retail shops and try the beauty products before actual purchase. For example- Lipstick color shades ordered online may substantially differ as compared to the actual expectation. Online beauty boxes have a limited choice and variety, as each beauty box has only one core beauty product of consumer's choice along with other sample surprise product testers. On the contrary, other cosmetic beauty product websites and retail shops provide a wide variety of beauty products and choices. Females have a perceived risk, as they are skeptical about the quality of the beauty product sample testers, which could affect their skin and are concerned whether it would fit their personal beauty needs and match with their expectations.

DISCUSSION AND IMPLICATIONS

This study contributes to the current literature on Behavioral reasoning theory by examining the contextual 'reasons for' and 'reasons against' adoption of BxSOS. There exists a study focusing only on the adoption factors of fashion and beauty SOS (Woo, & Ramkumar, 2018) and no study discusses the resistance and adoption factors of BxSOS in a single framework in the context of a developing country like India. This study mainly highlights the 'reasons for' and 'reasons against' adoption using BRT in the context of BxSOS which makes the study novel. This study uniquely contributes to the literature on consumer behavior in BxSOS and SOS.

The findings of this study show the context-specific 'reasons for' adoption such as - convenience, ubiquitous, hedonic shopping motivation, social influence and price consciousness. As per the path coefficient of the reasoning construct, Hedonic shopping motivation (β=0.77), is one of the most influencing reasons for the adoption of BxSOS. Female consumers having average education possess sizable disposable income, which they can invest in self-grooming and subscription boxes add the element of surprise and suspense, so they are attracted towards online subscription of beauty boxes. They are also mainly influenced by their peers for subscribing to the beauty boxes.

The 'reasons against' adoption of BxSOS are traditional barrier, choice/variety, relative advantage and perceived risk. 'Choice and Variety' which emerged as 'reason against' in this study, contradicts the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

mobile shopping study, as it is the 'reason for' the adoption of mobile shopping (Gupta, Gupta, Arora, & Arora, 2017). BxSOS like Fab-bag provide one beauty product in the beauty box for the subscription amount and other products are small quantity trial testers, so female consumers consider it as a limitation in terms of choice/variety during the selection of the beauty product. Also, there are exclusive online websites for beauty products like Nykaa, Purple and Apalva offering personalized beauty products of their choice. This study provides valuable insights to the marketers of BxSOS.

Some of the female consumers still believe in testing the beauty products in person and purchasing it from a retail store, as they are beauty conscious and some of them have sensitive skin and allergic reactions to the chemicals in beauty products which act as a traditional barrier. The marketers can improve the 'reasons for' and critically concentrate on the 'reason against' adoption of BxSOS. This study uniquely highlights the female consumers of a developing country like India regarding their buying behavior of BxSOS. This study makes an important contribution by finding out that Indian female consumers in urban cities are ready to experiment and accept new concepts like BxSOS; however, they prefer variety and choice in beauty boxes. This study also contributes to BRT by adding new reason against adoption – "variety and choice" in the context of BxSOS. This is because, in every subscription box, consumers get one or two products with limited choice options and remaining are trial samples of beauty products. Indian female consumers are persuaded by social influence and beauty is one of the important topics of discussion among females, so consumer delight needs to be maintained by BxSOS. This study suggests the managers formulate strategies, so as to provide more choice/variety of products in the beauty box for the female consumers to choose at the time of subscription to attract and retain more consumers. The marketing managers should also study the marketing strategies adopted by the online fashion and beauty product websites to continuously upgrade their offerings in terms of personalization of beauty products, competitive pricing of the beauty boxes and promotional offers specifically curated for the consumers.

This research makes a unique contribution by applying the BRT theory to study the adoption of BxSOS in a developing country like India, by considering only female consumers. In India, women's employment is increasing and hence decision-making power in terms of buying is also improving among females. The BxSOS is a new concept; still, female consumers are ready to experiment and enjoy adopting it. This finding is in sharp contrast to the orthodox Indian culture which bears a long glowing heritage, where personal cosmetic grooming skills and beauty care are passed as a lineage from mother to daughter since generations as part of the tradition.

This study highlights the distinctive adoption factors in the context of BxSOS, which will help the marketers and managers to work further upon these factors to formulate suitable marketing strategies. This study also finds that value (openness to change) does not affect the 'reason against', as females are more open to experimenting with new beauty products. This study uniquely contributes to the innovation diffusion theory by studying a new concept of BxSOS adoption by female consumers in India.

LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

There are many studies on online shopping in India (Kim and Peterson, 2017; Lamberton and Stephen, 2016; Ho & Chen, 2014; Kim et al., 2014; Kim et al., 2014; Thakur and Srivastava; Jiang, & Jones, 2014); however, no study exists on the online subscription of beauty boxes in India. Although this is the first study to understand the consumer behavior regarding BxSOS in a developing country such as India, this study has several limitations, as the findings of the survey reported are only for the female

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

consumer segment in India. In the future, further studies can be conducted to understand the actual usage of BxSOS in addition to the behavioral intention using the Behavioral reasoning theory. The 'reasons for' and 'reasons against' adoption can differ across various cultures, so it can be further studied in other countries and cultural contexts with various demographic variables- age, gender and income group on a comparative basis. Future studies can be conducted to provide the comparative analysis of adoption of BxSOS in developing countries and developed countries, which will provide more valuable insights. There are other subscription boxes like Bakebox - baked goodies boxes, Flintobox - Toy boxes of kids for child development and the Gourmet box - Gourmet food & ingredients box which can be studied using the BRT theory. The moderating effect of experience with technology and demographic factors can be studied further. Despite the limitations, this study provides valuable insights to academic scholars and marketers to develop strategies to market BxSOS.

CONCLUSION

This study discusses the 'reasons for' and 'reasons against' adoption of BxSOS in a developing country like India. The context-specific 'reasons for' adoption of BxSOS are - convenience, ubiquitous, hedonic shopping motivation, social influence and price consciousness and 'reasons against' are Traditional barrier, Choice and Variety, Relative Advantage and Perceived Risk. This study contributes to the existing literature on female consumer behavior using BRT. This study provides vital insights to the marketers by understanding the 'reasons for' and 'reasons against' adoption of BxSOS to help them formulate suitable strategies.

Chapter 50
Understanding Vietnamese Consumer Intention to Use Online Retailer Websites:
Application of the Extended Technology Acceptance Model

ABSTRACT

This study examines the applicability of an extended technology acceptance model (TAM) that incorporates trust, perceived risk, and self-enhancement as antecedents to the TAM constructs. Data collected from 299 Vietnamese online consumers, through a self-administered survey, were entered into a structural equation model using AMOS 23 to establish causality. The results partially confirm the applicability of TAM to the online shopping intentions of Vietnamese consumer, though contrary to expectations, perceived ease of use does not predict behavioral intentions. Trust and self-enchantment fit well with the TAM; the inclusion of perceived risk as an antecedent is questionable. The findings offer new opportunities for explaining TAM theory in light of Schwartz's value dimensions. This article thus concludes with a discussion of the research contributions and implications.

INTRODUCTION

With a basis in the theory of reasoned action (TRA; Ajzen & Fishbein, 1980), the technology acceptance model (TAM) proposed by Davis (1989) is one of the most prevalent behavioral models applied to explain users' technology acceptance (Venkatesh & Davis, 2000). The TAM offers a robust, parsimonious, dominant, and simple model for explaining human behavior in action, especially in e-shopping or e-commerce environments (Davis, 1989). Despite its parsimoniousness though, researchers question the universality of the TAM, especially in cultures marked by high power distance, low uncertainty avoidance, and high collectivism (McCoy, Galletta, & King, 2007). Venkatesh (2000) also cites the TAM's parsimony as a critical limitation of the theory. Noting this limitation, as well as the simplicity and robustness of the TAM theory, scholars have attempted to add variables from related theories to capture other key determinants that might influence consumers' purchasing intentions (Tong, 2010), such as perceived risk (Featherman & Pavlou, 2003; Pavlou, 2003) and trust (Gefen, 2004; Gefen, Karahanna, & Straub, 2003). Pavlou (2003) notes the increasing incorporation of both trust and perceived risk in the TAM, though as people grow more accustomed to e-commerce, they may perceive fewer risks (Ko, Jung, Kim, & Shim, 2004). Online retailing has continued to grow exponentially, such that the 1.66 billion global digital buyers in 2016 are expected to increase to 2.14 billion by 2021 (Rosengren, Lange, Hernant, & Blom, 2018). Furthermore, trust and perceived risk appear pertinent for millennial consumers, who tend to be risk-takers and thus perceive less risk than previous generations (Aruna & Anitha, 2015). To test these ideas, we conduct this research in Vietnam, where a large portion of the population is young (median age is about 29 years), and urbanization is accelerating. Furthermore, Vietnam is an emerging country, located in a strategic political and economic position in Southeast Asia, attracting many multinational companies in the world to invest and do business. Vietnam has a population of 100 million people, high economic growth rate, good Internet infrastructure covering 60% of its population, and 72% of its population uses smartphones, so e-commerce characterized by interactions between businesses' websites and customers is expected to significantly grow in the coming time. (Bui et al., 2020). Thus, a reassessment of whether perceived risk and trust should be included in the TAM, conducted in this southeast Asian country, is pertinent and justified, and it may assist in generalizing prior findings to similar, rapidly developing countries.

We also focus on Vietnam because more than half of its population uses the Internet as of 2017. Forsythe, Liu, Shannon, and Gardner (2006) reveal that more frequent shoppers who spend more money on online shopping perceive more significant benefits and less risk of Internet shopping. As Easley and Madden (2000) argue, we believe that researchers should be skeptical of results until they have been successfully replicated. By testing the applicability of the TAM in a non-Western, collectivist country, we seek to address several of these research gaps. According to Hofstede's website, Vietnam scored 70 on power distance, 80 on collectivism, 30 on uncertainty avoidance, and 40 on masculinity. Therefore, we test the applicability of the TAM to Vietnamese consumers' online shopping intentions, while we also consider whether it is appropriate to include perceived trust and risk as antecedents of TAM constructs in this developing Southeast Asian country.

According to Schwartz et al. (2012, p. 664), values are "trans-situational goals, varying in importance, that serve as guiding principles in the life of a person or group." They likely influence consumer behavior (Piscicelli, Cooper, & Fisher, 2015), in that values can be instrumental for behavioral intentions or affect behaviors through surrogate variables, such as attitude (Ramayah, Lee, & Mohamad, 2010). Schwartz's (2012) value taxonomy describes ten basic values divided into four higher-order categories: openness to

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

change, conservation, self-enhancement, and self-transcendence. Bridges and Florsheim (2008) also cite utilitarian and hedonic online shopping goals as guides of consumer behavior. By definition, hedonism refers to fun and playfulness and reflects the experiential side of shopping; utilitarianism reflects a conception of task relation and rationality, often described in terms used to evaluate work performance (e.g., success, accomplishment) (Scarpi, 2012). According to Kostelijk (2016), the achievement and power dimensions of the Schwartz value taxonomy relate to utilitarian value propositions; they are elements of the self-enhancement category. Thus we predict that self-enhancement might serve as an antecedent of consumer purchase intentions. Unfortunately, little research has sought to include Schwartz's values in TAM theory. With this study, we investigate the extent to which self-enhancement values (achievement, power, and hedonism) predict online purchase intentions among Vietnamese consumers, with trust, included as a possible mediating variable. A person (or group) in any culture may have a different value orientation than the broader culture, so similar to McCarty and Shrum (2000), we use individual consumers as the unit of analysis, rather than the culture. Furthermore, regardless of geographical location, we assume the universality of self-enhancement considerations (Sedikides, Gaertner, & Vevea, 2005).

LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

Testing the Core TAM

The theoretical basis for this study is the well-known technology adoption model, famous for its predictive power, which makes it applicable across various situations (Venkatesh, 2000). To derive the research model for this study, we started with the TAM. According to Davis (1989), TAM theory postulates that perceived usefulness and perceived ease of use are critical determinants of a person's behavioral intentions to use a technology; perceived usefulness (PU) is "the prospective user's subjective probability that using a specific application system will increase his or her job performance within an organizational context" (Davis, Bagozzi, & Warshaw, 1989, p. 985), and perceived ease of use (PEU) refers "to the degree to which the prospective user expects the target system to be free of effort" (Davis et al., 1989, p. 985). Both PEU and PU are crucial determinants of consumers' behavioral intentions (BI), which provide, according to the TRA (Ajzen & Fishbein, 1980, p. 288), "a measure of the strength of one's intention to perform a specified behavior," such as purchasing online. Greater PEU is instrumental for increased performance (Davis, 1989), and PEU also has a direct effect on PU (Agag & El-Masry, 2016; Venkatesh & Davis, 2000).

With these insights, the TAM receives substantial empirical support in terms of its ability to explain consumers' intentions to accept various types of technology and purchase online (Agag & El-Masry, 2016; Kim et al., 2008; McCoy et al., 2007; Pavlou, 2003; Tong, 2010). We seek to confirm the applicability of the TAM in Vietnam, though as Ajzen and Fishbein (1980) note when extending a model, new variables must be compatible with the existing ones. Therefore, to extend the TAM to any "unusual" context, we first must confirm the applicability of the model to that context. We apply the TAM to an online retail context to examine the relationships of Vietnamese consumers' PEU, PU, and BI toward online retailers' sites, with the prediction that the extent to which an online retailer's site is perceived as easy to use increases consumers' PU and intentions to shop. Furthermore, if an online shopping site appears useful, consumers are more likely to purchase from it. Therefore,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H1: Consumers' perceived ease of use of online retailers' sites has a positive effect on the perceived usefulness of those sites.
H2: Consumers' perceived usefulness of online retailers' sites is positively related to their intentions to use those sites.
H3: Consumers' perceived ease of use of online retailers' sites has a positive effect on their intentions to use those sites.

Inclusion of Trust and Risk in the TAM

Trust in our study context is the subjective belief that an online store will fulfill its transactional obligations, as understood by the consumer (Kim et al., 2008). We use the definition of trust offered by Jarvenpaa, Tractinsky, and Saarinen (1999), as a consumer's willingness to rely on the seller, even if such action makes the consumer vulnerable to the seller. Because trust in the salesperson does not exist in online shopping settings, we refer to trust in the merchant organization (Jarvenpaa, Tractinsky, & Vitale, 2000). Another pragmatic approach to trust defines it "as a mechanism to reduce the complexity of human conduct in situations where people have to cope with uncertainty" (Grabner-Kraeuter, 2002, p. 44). Because of the uncertainty and complexities of online shopping environments, previous research articulates the importance of trust as a success element for online shopping. For example, with data from Australia, Israel, and Finland, Jarvenpaa et al. (1999) show that trust is instrumental for forming favorable attitudes, which increase consumers' willingness to purchase from online stores. Gefen et al. (2003) also find that consumer trust influences purchase intentions toward e-vendors. With a cross-cultural sample drawn from India, the United States, and Canada, Ganguly, Dash, Cyr, and Head (2010) identify trust as a significant predictor of purchase intentions. Agag and El-Masry (2016) identify a similar instrumental influence of trust on purchase intentions. Furthermore, theoretical and empirical evidence supports including trust in the TAM, in that trust influences both PU and PEU (Chircu, Davis, & Kauffman, 2000; Gefen & Straub, 2003; Pavlou, 2003). Following this research tradition, we anticipate a positive influence of trust on PEU and PU. Similar to Gefen et al. (2003), we also postulate that PU is a consequence of trust.

Perceived risk is another commonly identified consequence of trust (Ganguly et al., 2010). Risk perceptions have negative effects on consumer purchase intentions in online shopping settings, and research indicates that consumers prefer Internet stores that appear less risky (Jarvenpaa & Todd, 1997; Jarvenpaa et al., 2000; Tong, 2010). The influence of perceived risk on BI also relates to the notion of perceived behavioral control from the theory of planned behavior (Ajzen, 1991). In an online shopping context, consumers may perceive various types of risk, including financial, product performance, psychological, and time/convenience loss risk (Forsythe & Shi, 2003).

Therefore, trust in online retailers should positively influence consumers' attitudes toward online retailing sites and their BI (Limbu, Wolf, & Lunsford, 2012; Pavlou, 2003). It also relates negatively to the perceived risks of an online purchase; the more a consumer trusts the retailer, the less he or she will perceive risk associated with its site (McKnight, Choudhury, & Kacmar, 2002; Pavlou, 2003). In turn, the perceived risk might negatively influence online consumers' BI (Featherman & Pavlou, 2003; Park, Lee, & Ahn, 2004). With data from Chinese and U.S. samples, Tong (2010) finds that fewer Chinese consumers tend to trust e-commerce, and they also perceive higher risks of Internet shopping. We expect similarly culturally defined outcomes for our research. That is, with the recognition that including trust and perceived risk in the TAM is well supported, we argue that customers from different cultural

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

backgrounds assign differing emphasis to various aspects of a shopping website (Singh, Zhao, & Hu, 2005), and we predict:

H4a: Consumers' trust in online retailers has a positive effect on their perceived ease of use of online retailers' sites.
H4b: Consumers' trust in online retailers has a positive effect on their perceived usefulness of online retailers' sites.
H4c: Consumers' trust in online retailers has a positive effect on their intentions to use online retailers' sites.
H4d: Consumers' trust in online retailers has an adverse effect on their perceived risk of online retailers.
H5: Consumers' perceived risk of online retailers has an adverse effect on their intentions to use online retailers' sites.

Including Self-Enhancement in the TAM

Personal values drive human behavior through their focus on individual motivations and desires (McCarty & Shrum, 2000; Ramayah et al., 2010). Self-enhancement relates to individualistic values in "the extent to which they motivate people to enhance their interests" (Follows & Jobber, 2000, p. 729). It has positive associations with specific consequences, such as convenience, effort, and cost involved (Ramayah et al., 2010). This variation of motivation enables people to feel good about themselves and maintain self-esteem (Blekesaune, 2015). Self-enhancement values in the Schwartz taxonomy consist of three basic values: power, reflecting social status and prestige, as well as control and dominance over others; achievement, which emphasizes personal success attained by demonstrating competence, according to social standards; and hedonism, referring to pleasure and sensual gratification for its own sake (Schwartz, 2007). Barnes and Pressey (2011) also note that arousal and individualism are critical drivers of higher-order needs (belonging, self-actualization) in the virtual world. Purchase intentions are need driven, so we anticipate that they are guided by some need and desire for the self or extended self. By acquiring a material good (i.e., purchasing), the consumer takes possession of a tangible object (Van Boven & Gilovich, 2003), which can constitute a proclamation of power and achievement. Another key reason for purchasing is to bring happiness (Van Boven & Gilovich, 2003). We posit that self-enhancement has a positive effect on consumers' intentions to purchase from online retailers. However, little consumer research establishes empirical support for the effect of self-enhancement on trust. Despite calls from Homer and Kahle (1988), we do not know of any studies that investigate possible mediating routes that might explain the positive effect of self-enhancement on online purchase intentions. Therefore, we hypothesize:

H6a: Self-enhancement has a positive effect on consumers' trust in online retailers.
H6b: Self-enhancement has a positive effect on consumers' intentions to use online retailers' sites.
H7: Consumers' trust in online retailers mediates the effect of self-enhancement on their intentions to use online retailers' sites.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Control Variables

In line with relevant prior literature, we anticipate that several other variables might affect the hypothesized relationships. As control variables, we include purchase frequency (Pavlou, 2003), income per month, gender, and age (Nagra & Gopal, 2013).

METHODOLOGY

Sample and Data Collection Procedure

The data collection for this study took place in ten branches of a large commercial bank located in Hanoi and Ho Chi Minh City, Vietnam. With the help of the bank executive and employees, customers who visited the branches were approached and asked to take part in an online survey. Interested customers were provided a link to survey questionnaire, administered via Survey Monkey. The participants could complete the survey at the branch using computers or at home. The data were collected from May 1 through July 31, 2018. The participants included in this study were screened for English proficiency, so they all were able to read, write, and speak English, and they completed the questionnaires in English. Customers of the bank's branches were concerned because with the help of branch managers and employees, these customers were directly approached when going to the branches to make banking transactions to receive the questionnaire link. Doing so is expected to increase the number of survey respondents. Furthermore, only customers who were fluent in English would be selected because e-commerce is no longer limited to a country border and these English-proficient customers could completely compare goods and prices of companies in the world in order to make their optimal buying decisions. The sample included only people who had made at least one online purchase in the prior six months. They were asked to respond to the questionnaire based on their latest online purchase. Participants were given a small monetary gift in appreciation. Three hundred six participants completed the survey, and the final sample included 299 after we removed 7 cases due to missing responses.

About 67% of the respondents are women, and 65% are married. In terms of educational background, most of the respondents have at least a bachelor's degree (90%). The median age is 31–35 years. The respondents purchased online, on average, once every three months. The median income per month is 15–20 million VND (approximately 650–850 USD).

Measurement Instruments

The construct operationalization relies on established scales from pertinent literature (see the Appendix for specific construct items). For the trust, we used a seven-item scale adapted from Jarvenpaa et al. (1999). The perceived risk measure is based on four items derived from Forsythe and Shi (2003) that covers four types: financial risk, product performance risk, psychological risk, and time/convenience loss risk. We measured self-enhancement with a six-item scale from Schwartz (2007), covering three fundamental human values: achievement, power, and hedonism. Perceived ease of use, perceived usefulness, and behavioral intention comprise four, four, and three items, respectively, and were adapted from Pavlou (2003). The four control variables reflect the purchase frequency (Pavlou, 2003), income per

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

month, gender, and age (Nagra & Gopal, 2013). The data were collected through a structured questionnaire with all the constructs, most of them measured on seven-point Likert scales.

ANALYSIS AND RESULTS

Measurement Model Evaluation

Confirmatory factor analysis (CFA) in AMOS 23 applied to all the multi-item scales: self-enhancement, perceived risk, trust, perceived usefulness, perceived ease of use, and intention. The CFA results exhibited sufficient overall model fit; all the fit indices exceed conventional cutoff values (Vandenberg & Lance, 2000). Specifically, the overall chi-square for this model was 548.05 ($p < .001$) with 284 degrees of freedom, CMIN/DF = 1.93, comparative fit index (CFI) = .95, Tucker-Lewis index (TLI) = .95, incremental fit index (IFI) = .95, and root mean square error of approximation (RMSEA) = .06. We find strong convergent validity for all items except two trust items, in that they load significantly on their intended constructs ($\geq .50$). We checked for discriminant validity by observing the interconstruct correlations, which were significantly different from 1. The average variance extracted (AVE) for each construct also exceeds the square of its largest inter factor correlation (Fornell & Larcker, 1981). Table 1 provides the correlation matrix for the constructs. Adequate discriminant validity is evident for all constructs because the diagonal elements are greater than the off-diagonal elements.

Table 1. Correlation between constructs

Construct	1	2	3	4	5	6
1. Intention	**0.91**					
2. Perceived risk	0.55	**0.73**				
3. Perceived usefulness	0.88	0.52	**0.88**			
4. Perceived ease of use	0.77	0.56	0.81	**0.83**		
5. Self-enhancement	0.49	0.33	0.52	0.57	**0.68**	
6. Trust	0.73	0.56	0.70	0.64	0.46	**0.79**

Note: Values on the diagonal are the square roots of the AVE.

With regard to reliability, all constructs present desirable levels of composite reliability (CR) and exceed the .60 minimum recommended (Bagozzi & Yi, 1988): intention (CR = .94), perceived risk (CR = .82), perceived usefulness (CR = .93), perceived ease of use (CR = .89), self-enhancement (CR = .61), and trust (CR = .89). Regarding the AVE, all constructs except self-enhancement exceeded the .50 threshold. Therefore, for all constructs, the indicators are sufficient and adequate in terms of how the measurement model is specified.

Structural Model

Testing the Core TAM

To achieve our first research objective to test the applicability of the TAM in Vietnam, we run the core TAM first, with ease of use, usefulness, and behavioral intentions. The chi-square of the model is 120.43, df = 73, CMIN/DF= 1.65, GFI = .95, CFI = .98, TLI = .98, IFI = .99, and RMSEA = .05. Our findings confirm a positive and significant link between PEU and PU (β = .88, $p < .001$), in support of H1. Consumers' PEU concerning online retailers' sites has a positive effect on their PU of those sites. The relationship of PU and BI (β =.93, $p < .001$) also is significant, suggesting that consumers' perceptions of the usefulness of online retailers' sites relate positively to their intentions to use them, as we predicted in H 2. However, contrary to our prediction in H3, we find no significant direct link between PEU and BI (β = -.01, $p = .90$), a finding that also appears in previous research. For example, Pavlou (2003) does not find any significant association between PEU and intentions to transact, and Davis (1989) indicates that ease of use might affect BI indirectly, through PU. Together, this evidence indicates that perceived usefulness mediates the impact of perceived ease of use on behavioral intentions. We check for the specific indirect effect of PEU on BI with bootstrapping in AMOS 23 (2000 samples, 95% confidence interval); the lower bound of the confidence interval is .71, and the upper bound is 1.38. Because 0 does not appear in the confidence interval, we can conclude that PU mediates this relationship (Preacher & Hayes, 2008). The TAM can predict the online shopping intentions of Vietnamese consumers.

Trust and Risk in the TAM

Following our second research objective, we extend the core TAM to include perceived risk and trust and rerun the model in AMOS 23. With trust and risk included, this TAM reveals a good model fit: chi-square = 414.97, df = 223, CMIN/DF= 1.86, GFI = .90, CFI = .96, TLI = .95, IFI = .96, and RMSEA = .05. Consumers' trust in online retailers relates positively to their PEU of the retailers' sites (β =.74, $p < .001$, H4a), the PU of the sites (β =.13, $p < .001$, H4b), and BI to use the sites (β =.22, $p < .001$, H4c). However, trust does not have a significant effect on perceived risk (β =.07, $p = 34$), so among the predictions in H4, we must reject H4d but find support for H4a–4c. Besides, we cannot confirm H5, because perceived risk does not exert any significant effect on BI (β = -.05, $p = .06$). This quasi-significant finding is congruent with research that indicates that as consumers increasingly shop online, they perceive lower levels of risk than they did previously (Sims & Xu, 2012; cf. Jarvenpaa et al., 1999), as do people who purchase online more frequently (Ko et al., 2004). Thus, we argue that trust fits well with the TAM, but the inclusion of perceived risk as an antecedent of BI might be questionable. In the past 20 years, with the massive expansion of the Internet and online businesses, consumers may feel less threat when it comes to shopping online than they did before.

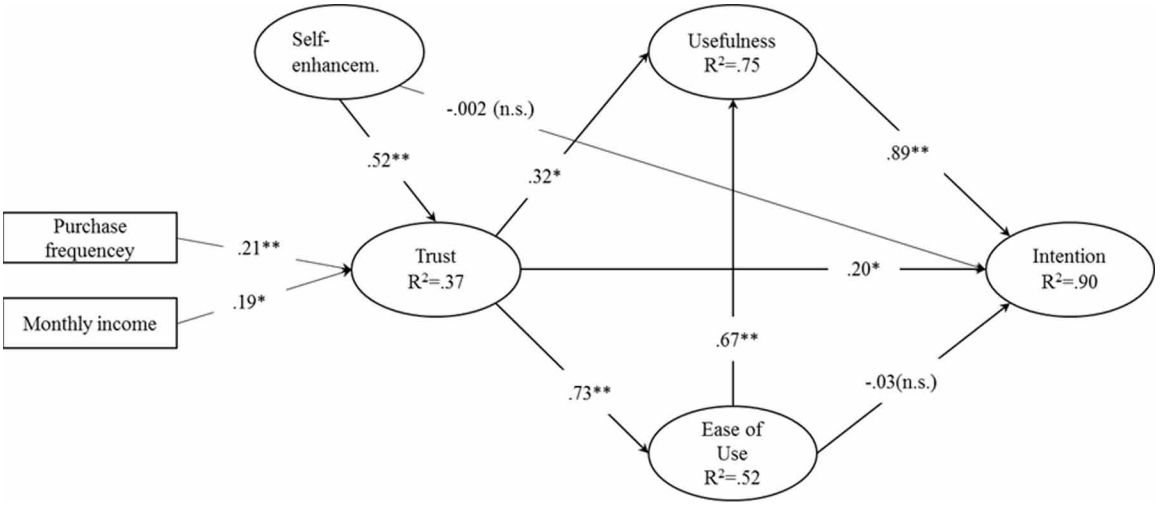
Self-Enhancement in the TAM

As detailed previously, we take a value perspective on the TAM and include self-enhancement, defined by the three lower-order values of achievement, hedonism, and power. We ran the model in AMOS 23 (see Figure 1) and test the hypothesized links among the constructs by estimating the structural equation model with the application of maximum likelihood (ML). The analysis reveals good model fit, with the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

following statistics: chi-square = 513.65, df = 269 ($p < .001$), CMIN/DF = 1.91, CFI = .96, TLI = .95, IFI = .96, GFI = .89, and RMSEA = .06. Because all the fit indexes match conventional cut-off values, we deem the model acceptable (Vandenberg & Lance, 2000). The standardized path coefficients, together with the corresponding *p*-values, are in Figure 1. We find that self-enhancement has a significant positive effect on trust ($\beta = .52$, $p < .001$), which confirms H6a and is in line with previous research. However, self-enhancement does not have a direct association with BI ($\beta = -002$, $p = .96$), and we cannot confirm H6b. This unexpected result might signal strong mediation effects in the self-enhancement–intention relationship. We ran a bootstrap analysis in AMOS, which reveals that trust mediates the effect of self-enhancement on BI ($\beta = .18$, $p < .05$, confidence interval from .08 to .34). Because 0 is not included in the confidence interval, we argue that H7 is supported.

*Figure 1. Research model with path coefficients. Notes: n.s. = not significant, **p < .01, *p < .05. Control variables are gender, age, purchase frequency, and monthly income.*



The variance explained by BI is very high ($R^2 = .90$) and well above that cited by other researchers, suggesting that the proposed model captures many significant variables that influence online purchase intentions among Vietnamese consumers, given the sample size. Therefore, extending the TAM by integrating trust is well supported, and the inclusion of self-enhancement (Schwartz value) is justified.

Of the control variables, only income per month and purchase frequency (Pavlou, 2003) have significant positive effects on trust, as we show in Figure 1. This result makes intuitive sense; more financially solvent and frequent consumers likely trust online retailers more. However, similar to Hasanov and Khalid (2015), we do not find any effect of gender or age on any of the endogenous variables in the research model. This result suggests some similarity in consumer behavior across the world (cf. McCoy et al., 2007).

DISCUSSION AND CONCLUSION

The primary purpose of this study was to test the applicability of the technology acceptance model to Vietnamese consumers' online shopping intentions and provide evidence in support of the inclusion of perceived risk and trust in the TAM. We also examine the extent to which the self-enhancement values in the Schwartz taxonomy (achievement, power, and hedonism) can predict online purchase intentions, both directly and indirectly through trust. The results broadly support the extended TAM, highlighting the important roles of self-enhancement, trust, perceived ease of use, and perceived usefulness in determining Vietnamese consumers' purchase intentions toward online retailers. This study thus makes both theoretical and practical contributions.

Contributions to Scholarship

The results show that TAM is applicable and useful for predicting consumers' online shopping intentions in Vietnam, an emerging, non-Western country. This finding is relevant and responsive to researchers' calls for more empirical evidence about the universality of TAM theory, especially in cultures marked by high power distance, uncertainty avoidance, and collectivism (McCoy et al., 2007). Consistent with the TAM, we find that perceived ease of use relates positively to perceived usefulness. Perceived usefulness is a significant determinant of behavioral intentions. However, contrary to the predictions of the TAM, but in line with Pavlou (2003), perceived ease of use has no significant direct effect on behavioral intentions. Instead, this effect is mediated by perceived usefulness, consistent with conclusions by Davis (1989). Perhaps learning how to use e-commerce websites is no longer a primary concern for today's consumers. Vietnamese consumers, who are generally young and highly educated, may not regard the perceived ease of use of retailers' sites as a crucial determinant of their purchase intentions.

This study integrates trust and perceived risk into the TAM in an online retailing context, revealing that trust is a direct antecedent of purchase intentions and an indirect determinant, through perceived usefulness; it does not have any significant adverse effect on perceived risk. Unlike previous studies (Jarvenpaa & Todd, 1997; Jarvenpaa et al., 2000; Tong, 2010) that report adverse impacts of risk perceptions on purchase intentions, we do not find any evidence of such a relationship. This finding is surprising; consumers in Asian countries typically are deemed risk-averse. We posit that an increasing number of Internet users also are online shoppers and perceive lower levels of risk associated with online shopping (Sims & Xu, 2012). The majority of our study participants also were urban, young, educated, and affluent, and they purchased products online relatively frequently. Thus, though trust fits well with the TAM framework, the inclusion of perceived risk as an antecedent is questionable.

Another novel contribution of this study reflects our attempt to integrate self-enhancement, one of Schwartz's human values, into the extended TAM, as an exogenous variable. Contrary to our hypothesis and the assertions of Bridges and Florsheim (2008), self-enhancement, comprised of achievement, power, and hedonism, does not function as a direct antecedent of online purchase intentions. Instead, trust mediates the relationship of self-enhancement with behavioral intentions. Consumers who strongly value self-enhancement are more likely to trust online retailers, which positively influences their purchase intentions toward those retailers. Trust thus emerges as a crucial mediating variable in the relationship between self-enhancement and purchase intentions. In light of research gaps and calls for more studies (Homer & Kahle, 1988), these findings offer important empirical insights into how self-enhancement can influence the purchase intentions of online consumers.

Applied Implications

Consumers' perceptions of the ease of use of online shopping influence their perceived usefulness, which in turn influences their intentions to use retailers' sites. If consumers find online retailers' sites to be easy to use, they will consider the sites useful and likely transact with them. Therefore, online retailers should focus on design, usability, and user experience when building their sites. To enhance user acceptance of retail sites, it is essential that the sites be consumer-friendly, making it easy to browse, use, understand, interact, and transact.

Trust in retailers is a central influence on consumers' purchase intentions, with both direct and indirect effects through perceived usefulness. Accordingly, online retailers must deliver on their promises and commitments, meet consumers' expectations, and offer superior customer service. It is also important that e-vendors ensure the reliability and performance of their websites to enhance consumers' overall shopping experiences.

Self-enhancement values in the Schwartz taxonomy influence consumers' trust in online retailers, which positively influences their behavioral intentions. Understanding consumers' values thus might help online retailers reduce the uncertainty and complexity of online shopping environments, which in turn increases their propensity to purchase. The achievement and power dimensions of Schwartz's self-enhancement value are closely related to the utilitarian value proposition and the functional aspects of a product or service (Kostelijk, 2016), so e-vendors could benefit from emphasizing the utilitarian aspects of their websites. Perceived utilitarian value can be enhanced by an easy and user-friendly website, complete and precise product information, and sales promotions. However, consumers' motivations to shop include both utilitarian and hedonic aspects, so online retailers also should ensure that their websites offer hedonic attributes, another component of self-enhancement value based on experiences of fun and playfulness (Babin, Darden, & Griffin, 1994). To improve consumers' hedonic shopping motivations, online retailers can design websites that are enjoyable and playful and reflect the experiential side of shopping (Scarpi, 2012), to help consumers engage in shopping for fun and enjoyment (Van Boven & Gilovich, 2003). Online retailers' pleasurable and interactive shopping environments might offer a variety of products and also incorporate peripheral cues, such as music, image, video, and so forth.

Limitations and Research Directions

The data for this study were collected mostly from a highly educated, convenience sample of Vietnamese consumers, which could create some selection bias and limit the generalization of findings. Further research should attempt to replicate these findings among a more diverse, random sample that varies in education, age, and income. Another limitation is the use of a cross-sectional design; therefore, the results do not demonstrate causal relationships. Instead, research might adopt a longitudinal approach. This study examines the indirect effect of Schwartz's self-enhancement value on online purchase intentions through the mediating influence of trust; continued studies might examine the effects of other personal values, such as openness to change, conservation, or self-transcendence.

APPENDIX

Table 2. Constructs used in the research model

	Mean	SD	Factor loading	Alpha
Trust	4.60	1.16		.88
This online retailer is trustworthy in general.			.87	
This online retailer wants to be known as one who keeps promises and commitments.			.88	
I trust this online retailer keeps my best interests in mind.			.83	
I find it necessary to be cautious with this online retailer.				
This online retailer has more to lose than to gain by not delivering on their promises.			.51	
This online retailer's behavior meets my expectations.			.83	
This online retailer could not care less about servicing a person from Vietnam.				
Perceived risk	3.99	.89		.81
Do not trust that my credit card number will be protected by this online retailer.			.78	
Difficult to judge the quality of a product/service of this online retailer.			.72	
Do not trust that my personal information will be kept private by this online retailer.			.83	
Faster/easier to purchase locally.			.56	
Self-enhancement	4.74	.99		.84
It's important to me to show my abilities. I want people to admire what I do.			.65	
Being very successful is important to me. I hope people will recognize my achievements.			.68	
It is important for me to be rich. I want to have lots of money and expensive things.			.65	
It is important to me to get respect from others. I want people to do what I say.			.61	
Having a good time is important to me. I like to "spoil" myself.			.69	
I seek every chance I can to have fun. It is important to me to do things that give me pleasure.			.78	
Perceived ease of use	4.79	1.18		.89
My interaction with the retailers' Web sites in Vietnam clear and understandable.			.82	
Interacting with the retailers' Web sites in Vietnam do not require a lot of mental effort.			.76	
I find the retailers' Web sites in Vietnam are easy to use.			.90	
I find it easy to locate the information that I need in the retailer's Web sites in Vietnam.			.82	
Perceived usefulness	4.60	1.28		.93
Overall, I find the retailer's Web sites in Vietnam are useful.			.87	
I think the retailer's Web sites in Vietnam are valuable to me.			.93	
The content on the retailer's Web sites in Vietnam are useful to me.			.90	
The retailer's Web sites in Vietnam are functional.			.82	
Behavioral Intention	4.66	1.42		.94
It is likely that I will transact with the web retailer in the near future.			.92	
Given the chance, I intend to use the retailer's website.			.92	
Given the chance, I predict that I should use the retailer's website in the future.			.90

Chapter 51
Reverse Logistics in E-Retaling

Senem Ergan
Namık Kemal University, Turkey

Ayşe Akyol
Trakya University, Turkey

ABSTRACT

Consumers mostly prefer internet for reasons such as accessing product immediately, convenience, time saving. However buying products without observing physically causes some troubles. This situation results in return of the purchased product. The return process that is going to be experienced by the customer who wants to return or change his/her product is important for the companies. Managing return process without troubles is going to affect loyalty, satisfaction, revisiting, repurchasing, consumers messages, which are going to be get across to his/her environment. Because of these reasons, it is imperative for the companies to pay attention to the reverse logistic activities that they will undertake for the end consumers. The aim of this chapter is to indicate the importance of reverse logistics in e-retailing.

INTRODUCTION

The elimination of borders with technology ensures the consumers to have the products from the other end of the world with one "click". Consumers can buy the product they want from the Internet, anytime, anywhere, and in the form of payment they want; they can easily compare models, colors and prices. Despite the many benefits of online shopping, some consumers consider that there are some risks of online shopping. Because consumers are acting according to the visuals and information given by the e-retailer. They cannot see, touch, try or test them closely thus they purchase the features which are promised about the product.The fact that the purchased product is not as expected (not being the suitable size, not having the specified features, etc.) or giving up after purchasing the product leads to a reverse logistics process between the consumer and the e-retailer. This process is one of the most important processes determining the fate of the relationship between e-retailer and consumer. Because, in today's conditions, not only the quality, function and utility of the product is important for consumers; but also

experience in the process of purchasing the product is important. This study examines reverse logistics, e-retailing and the relationship between reverse logistics and e-retailing.

BACKGROUND

There are many definitions in the literature related to the reverse logistics. The first definitions are found in the scientific literature in 1970s. Authors such as Zikmund & Stanton (1971), Guiltinan & Nwokoye (1974) and Ginter & Starling (1978) have used terms such as "Reverse Channels" or "Reverse Flow" instead of the concept of reverse logistics in their study these years. Also they related reverse logistics definitions to recycling (De Brito & Dekker, 2004, p.4). For example, Zikmund and Stanton (1971, p.35) named "reverse logistics" as "reverse distribution" and defined it as: "Conceptually, reverse distribution is identical to the traditional channel of distribution. The consumer has a product to sell and, in essence, he assumes the same position as a manufacturer selling a new product. The consumer's (seller's) role is to distribute his waste materials to the market that demands his product". Lambert and Stock (1981) defined reverse logistics as; "going the wrong way on a one-way street because the great majority of product shipments flow in one direction" (Rogers & Tibben-Lembke, 2001, p.129). Murphy (1986) made a similar definition with Lambert and Stocker and he said that reverse distribution may occur in three cases. These are;

- Customer initiative-voluntarily returned goods.
- Industry initiative-recycling.
- Govemment initiative-product recalls (Murphy, 1986, p.12).

When the studies carried out in the following years are examined, it is seen that the definitions have begun to differentiate. For example, according to Rogers and Tibben-Lembke (1998) reverse logistics is "the process of planning, implementing, and controlling the efficient, cost effective flow of raw materials, in-process inventory, finished goods and related information from the point of consumption to the point of origin for the purpose of recapturing value or proper disposal" (Rogers & Tibben-Lembke, 1998, p.2). Srivastava (2008:547) defines reverse logistics as "the process of planning, implementing, and controlling the efficient, effective inbound flow, inspection and disposition of returned products and related information for the purpose of recovering value".

Reverse logistics begins from end users (first customers) where used products are collected from customers (return products) and then attempts to manage end-of-life products through different decisions are undertaken including recycling (to have more raw materials or raw parts), remanufacturing (to resale them to second markets or if possible to first customers), repairing (to sell in the second markets through repairing), and finally, disposing of some used parts (Govindan et al., 2015, p.603). The important point here is; reverse logistics is not just the reverse of the forward logistics or supply chain (Bai & Sarkis, 2013, p.307).

REVERSE LOGISTICS AND E-RETAILING

Reverse Logistics

Reverse Logistics has become a significant concept in today's supply chain operations (Gencer & Akkucuk, 2016, p.125). The products can take place in reverse flow in various situations. Generally, reverse flows are classified into commercial returns, returns with the warranty period, returns of end-of-use products, reusable container/boxes, etc. returns and others (Roghanian & Pazhoheshfar, 2014, p.348).

Blumberg (2005, p.66) classified the products falling under reverse logistics activities as:

- Products that are defective and need to be repaired or properly disposed of.
- Reusable, repairable or re-workable parts.
- Products that are robust but still left on the seller's shelf for being returned or not sold by the buyer.
- Products and supplies that are ongoing to life cycle but are recalled or obsolete.
- Recycled and reusable products, materials and goods that have been discarded.
- End of life products.

Reverse logistics is applied in many industries, including those producing chemicals, aircraft, computers, medical, automobiles, appliances and steel items (Roghanian & Pazhoheshfar, 2014, p.348, Gonzalez-Torre & Adenso-Diaz, 2006, p.528, Dowlatshahi, 2000, p.144). The efficient use of reverse logistics can help a firm to compete in its industry, especially when confronting intense competition and low profit margins (Dowlatshahi, 2000, p.144).

Reverse logistics examples can also be seen in the service sector. For instance, a holiday tour operator may need to repatriate its clients at short notice due to disease, civil unrest or severe weather conditions (Rushton et al., 2010, p.601).

There are three known features of reverse logistics (Shaik & Abdul-Kader, 2014, p.88);

- High uncertainties of supply on time, quantity and quality.
- Complexities in operations due to recovery options.
- Barriers.

A well-managed reverse logistics program can lead to savings in inventory handling, transportation and waste disposal costs, and can also increase customer satisfaction (Shaik & Abdul-Kader, 2014, p.88). Implementation of reverse logistics especially in product returns would allow not only for savings in inventory carrying cost, transportation cost, and waste disposal cost due to returned products, but also for the improvement of customer loyalty and futures sales (Roghaniana & Pazhoheshfar, 2014, p.348).

Reverse logistics is applied in many sectors and can provide many advantages to a company when it is applied effectively. In a reverse flow products can be in many situations as; commercial returns, warranty returns, end-use returns, reusable package returns. An effective reverse logistics operation provides some advantages to company directly as increased customer satisfaction, reduced resource investment levels and reduced storage and distribution costs (Govindan et al., 2012, p.204).

Many companies are unable to handle the complex networking necessary to have an efficient reverse logistics process. These companies are therefore outsourcing all or part of the reverse logistics process to third-party providers (Govindan et al., 2012, p.206).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reverse logistics activities constitute 3-4% of a company's total logistics costs. Companies who purchase reverse logistics assistance from third party providers could reduce up to 10% of their company's annual logistics costs (Govindan et al., 2012, p.206).

Reverse logistics is not optional but mandatory for successful companies, insofar as it can lead to both economic and strategic advantages through the reuse and recovery of materials, analyzing the whole productive process of a particular product (García Rodríguez et al., 2013, p.584).

Reverse Logistics Activities

There are different definitions in the literature related with reverse logistics activities.

Table 1. Reverse Logistics Activities

Author – Study Name	Reverse Logistics Activities
M. Thierry, M. Salomon, J. Van Nunen, L. Van Wassenhove (1995:118) - *Strategic issues in product recovery management*	• Reuse / Resale • Repair • Refurbishing • Remanufacturing • Cannibalization • Recycling • Incineration • Landfilling
M. Fleischmann, H. R. Krikke, R. Dekker, S. D. P. Flapper (2000:657) - *A characterisation of logistics networks for product recovery*	• Collection • Inspection / Separation • Re-processing • Disposal • Re-distribution
M. P. De Brito, R. Dekker (2002:13-14) - *Reverse logistics: A framework*	• Collection • Inspection / Selecting / Sorting • Re-processing / Direct Recovery • Redistribution
C. Zhao, W. Liu, B. Wang (2008:351) - *Reverse logistics*	• Resale / Reuse / Redistribution • Repair / Refurbishing • Remanufacturing • Recycling • Incineration • Landfill
S. Agrawal, R. K. Singh, Q. Murtaza (2015:77-78) - *A literature review and perspectives in reverse logistics*	• Product acquisition/Gate keeping • Collecting • Inspection and sorting • Disposition

Thierry et al. (1995, p.118), gathered reverse logistics activities in three stages: *Direct reuse*; reuse / resale; *Product recovery management*; repair, refurbishing, remanufacturing, cannibalization, recycling; *Waste management*; incineration, landfilling.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reuse / Resale

Reuse of products and materials is not a new process. Metal scrap brokers, waste paper recycling, and deposit systems for softdrink bottles are all examples that have been around for a long time. In these cases recovery of the used products is economically more attractive than disposal. In the recent past the growth of environmental concerns has given "reuse" increasing attention (Fleischmann et al., 1997, p.1).

Repair

The products are returned by the consumer/user to have it back in working order. The producer fixes or changes the damaged parts if necessary. It requires limited effort. Generally repaired products are comprehended as less quality products than those new products (Akdoğan & Coşkun, 2012, p.1642).

Refurbishing

The aim of the refurbishing is to bring used products to the stated quality.Quality standards are less rigorous than those for new products. After disassembling the used products into modules, all critical modules are inspected and fixed or replaced. Approved modules are reassembled into refurbished products. Military and commercial aircraft are examples of produrts that are refurbished. Refurbishing significantly enchances their quality and extends their service-life (Thierry et al., 1995, p.119).

Cannibalization

The aim of cannibalization is to rescue the limited parts of used products for reusage in other reverse logistics activities (i.e. repair, refurbish, remanufacture). There is no strict quality standard for cannibalization. It depends on the process where parts will be reused (Akdoğan & Coşkun, 2012, p.1643).

Remanufacturing

In reproduction, product value gained during fabrication is retained and and only the worn-out parts are replaced. For example, disposable cameras, mobile phones, printing presses, truck tires, automobile and airplane components and assembles, copy machines, and toner cartridges are reconditioned or remanufactured and resold (or leased) to end users. Remanufactured products incur costs that are 40–60% less than those incurred in delivery of new products (Kumar ve Putnam, 2008, p.312). Remanufacturing gives used products standards of quality as rigorous as original products with a lower cost (García Rodríguez et al., 2013:585). But remanufacturing centers require very high capital investment, are more technology-based and produce upgraded remanufactured goods (Srivastava, 2008, p.540).

Recycling

In recycling, products and components lose their identity and functionality (Thierry, 1995, p.120). Returned parts and products have to be transformed into raw material by means of melting, grinding etc. (Fleischmann, 1997, p.11). Recycling is the extraction of material to gain recyclable material for reuse in new products (Khor & Udin, 2013, p.73). In some fields, recycling of spent products is well established,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

mainly due to the profitability of recovering secondary materials from spent products. For example, in the paper industry and the metal industry, the use of scrap as a raw material for new products is routine (Schultmann, 2006, p.1035).

Incineration and Landfilling

The last alternative is to incinerate or landfill the returned products because of the limited capacity of waste yards. In case of providing no gain to the company even being involved in recovery process, it can be seen as an option (Akdoğan & Coşkun, 2012, p.1642).

According to Agrawal et al. (2015, p.77-8) the reverse logistics process contains four main steps:

Product Acquisition / Gate Keeping

Product acquisition is the process of acquisition of used prod-ucts, components or materials from the end users for furtherprocessing. Since product returns are uncertain in terms of time, quantity and quality, their acquisition is important for the success of reverse logistics. Gate keeping represents the main entrance of reverse logistics. It is a set of practices performedusually by retailers to identify the products which are allowed intothe system or given back to the user after resolving issues at theirend (Agrawal et al., 2015, p.78).

Collecting

Collection, which is the first of the reverse logistics activities refers to bringing the products from the customer to a point of recovery (De Brito & Dekker, 2002, p.13). Collecting consist of used, damaged, unwanted or outdated products, as well as packaging and shipping materials from the end-user or the reseller (Rogers & Tibben-Lembke, 1998, p.10).

Inspection and Sorting

Product returns may be commercial returns, service returns, distribution returns or end of life returns. So a separate inspection of each item is required for sorting the products. Its overall appearance and state of the constituting elements need to be evaluated. Products and components are sorted out based on this evaluation (Agrawal et al., 2015, p.78).

Disposition:

There are two types of disposition (Krumwiede et al., 2002, p.328):

1. *On-site disposition* involves activities that take place at the customer's facility to handle issues related to product concerns. The product may be repaired or replaced on-site.
2. *Off-site disposition* involves shipping the defective product to a different facility for repair, replacement, or disposal. Companies such as Wal-Mart use dedicated redistribution or processing centers for their off-site processing efforts.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Reasons of Reverse Logistics

The main reasons of the growing interest in reverse logistics can be called as business factors and environmental factors. In the early days, this interest was originated from the increasing attention of consumers about environmental impacts of used products, environmental legislation, waste management, environmental issues and pollution reduction. Later on, the economical advantages of using return products, increasing customer satisfaction, rising market share, decreasing costs, and added value to the logistics network have become interesting contents of reverse logistics (Keyvanshokooh et al., 2013, p.10183).

According to De Britto ve Dekker (2002, p.6) the reasons of applying reverse logistics are classified as; economics (direct-indirect), legislation and extended responsibility.

Economics as a driving force relates to all recovery actions where the company has direct or indirect economic benefits. The previous regards profit from recovery actions, e.g. because of abating costs, dwindling on the use of materials, or obtaining valuable spare parts. This provides direct benefits to companies. As a result of the increased environmental awareness of the society, improving relations with its customers and increasing their reputation, have become economical reasons that provide benefits to companies.

Legislation is the introduction of any legal obligation that a company must re-evaluate its products or accept them back, e.g. packaging recycling quotas in Europe.

Extended responsibility is that the operator or organization which is responsible and acts in accordance with certain principles when carrying out activities related to reverse logistics.

De Britto ve Dekker (2002, p.8-9) also added that returns may originate from production, distrubition and consumer/user: *Manufacturing returns*; raw material surplus, quality-control returns, production leftovers; *distribution returns*; product recalls, commercial returns (e.g. unsold products, wrong/damaged deliveries), stock adjustments, functional returns; *customer/user returns*; reimbursement guarantees, warranty returns, service returns (repairs and spare-parts), end-of-use, end-of-life.

According to Tan and Kumar (2003, p.30-2) reasons of reverse logistics are:

- **Government Legislation:** Several countries have enacted environmental legislation that charges the producers with responsibility for the whole product life cycle. Some companies are not waiting to be forced into legislative compliance. They are preparing for the inevitable day when the producer will be made fully responsible for the disposal of the product at the end of its useful life. For example, Fuji Xerox in Asia is actively collecting used toners from laser printers for recycling as part of their reverse logistics program.
- **Shortening Product Life Cycles:** New designs are brought onto the market at an ever faster pace to persuade consumers to buy more often. While consumers have benefited from a greater variety and choice of products as well as improved performance, this trend inevitably results in more unsold products, more returns, more packaging materials, and more waste.
- **New Direct Channels of Distribution:** New channels are being developed to provide consumers with easier and quicker ways to purchase products. Direct channels (e.g. e-commerce) increase the likelihood of returned products, such as items damaged in transit. As direct channels serve customers not only locally but also globally, managing returns will become increasingly complicated and expensive. Thus, direct channels will add pressure on reverse logistics networks.
- **Market Forces:** Reverse logistics can also be used to replace customers' obsolete or slow moving inventories with newer goods. If existing parts held by the dealers are not selling well, companies

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

like Caterpillar Asia give their dealers a generous return allowance to Exchange for new parts that their customers really need. Caterpillar Asia has an e-commerce program for their dealers to return their existing parts in exchange for parts in new products.

- **Shifting of Power Within the Supply Chain:** Increased competition has enabled customers to become more powerful in the supply chain. A recent survey conducted in Singapore among logistics service providers confirms that the customers are rapidly becoming the most important driver of logistics management.

According to Blumberg (2005, p.183) end-users, return the products because of many reasons:

- The product does not work (partially or completely).
- Product damaged during shipment or when opened.
- The use of the product is very complicated / the usage instructions are not user friendly.
- The desired result or performance level is not compatible with the other items of the product.
- The product is in the wrong color or size.
- Product price is too high.
- Causes of other customer regrets (change of opinion, in fact only a request to rent or test, etc.).

Relations of Reverse Logistics With Some Concepts

Reverse logistics is constantly mixed with green logistics, green supply chain, waste management, and closed loop supply chain because the birth point of all is environmental protection and environmental friendly production. However, these concepts are similar to each other and are separated from each other.

Reverse Logistics and Forward Logistics

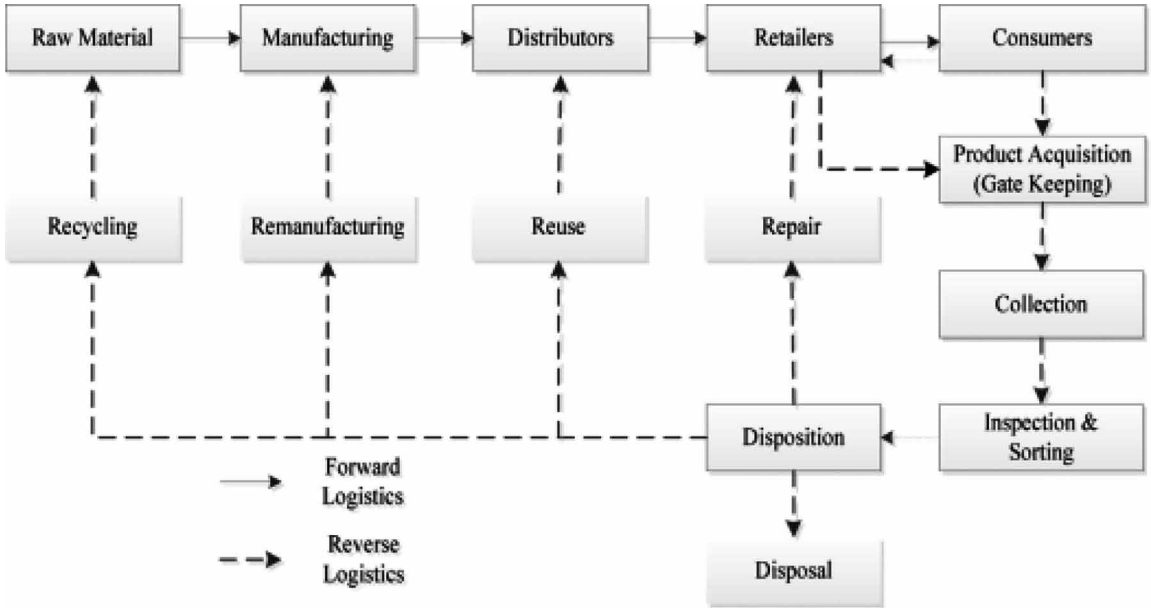
Logistics is *the process of planning, implementing, and controlling the efficient, cost effective flow of raw materials, in-process inventory, finished goods and related information from the point of origin to the point of consumption for the purpose of conforming to customer requirements.* Reverse logistics includes all of the activities that are mentioned in the definition above. The difference is that reverse logistics encompasses all of these activities as they operate in reverse (Rogers & Tibben-Lembke 1998, p.2).

In many industries where customers return products for warranty repair, replacement, remanufacturing, or recycling, reverse logistics costs are higher relative to forward logistics costs. The flow cost of a product backwards-from the consumer to the producer-is nine times higher than the cost of the same product-forward-to-consumer-flow. Often the transport, storage and / or processing of the returned item causes higher costs per item (Stock, 2008, p.25-5).

As it can be seen in Figure 1, the flow in the forward channel is towards the consumer, while in the reverse channel the consumer is moving towards the generator. In forward logistics, companies can predict what will be needed at each level. On the other hand, the reverse logistics flow is more sensitive and less predictable than the forward logistics flow (Tibben-Lembke & Rogers, 2002, p.271).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

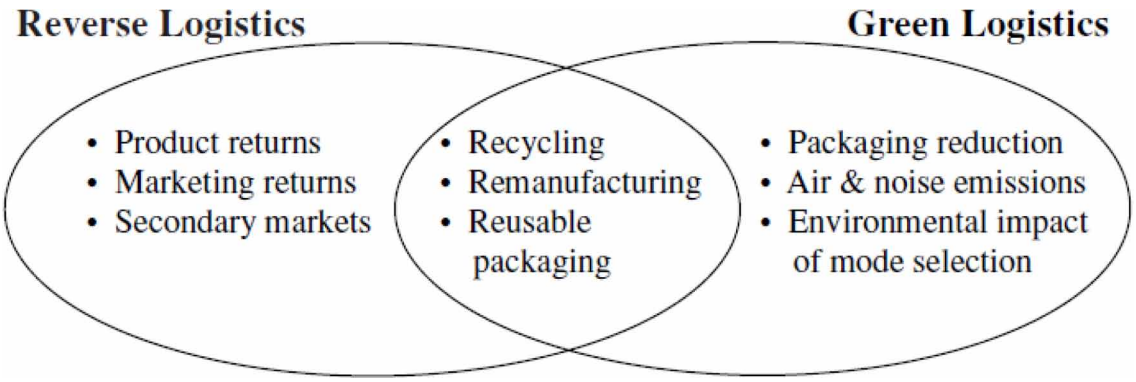
Figure 1. Process of forward logistics and reverse logistics
Source: *(Agrawal, Singh, & Murtaza, 2015).*



Reverse Logistics and Green Logistics

Green logistics describes all attempts to measure and the minimize the ecological impact of logistics activities (Gencer & Akkucuk, 2016, p.129). Reverse logistics and green logistics are two concepts that are often intermixed with each other. Although they have common features such as recycling, they both have different content.

Figure 2. Comparison of reverse logistics and green logistics
Source: *(Rogers, Tibben-Lembke, 2001)*



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Some green logistics activities can be called as reverse logistics. For example, the use of reusable products and reproduction are both in the field of reverse and green logistics. But, many green logistics activities are not related to reverse logistics. For instance, designing a disposable package that reduces energy consumption or requires less packaging is not a reverse logistics activity. Designing a product to use less plastic is not a reverse logistics activity, but it is in the field of reverse logistics to design a product to benefit from reusable packaging (Rogers & Tibben-Lembke, 1998, p.103).

Reverse Logistics and Waste Management

Waste management deals with the collection and processing of wastes efficiently (Şengül, 2011, p.410). Reverse logistics and waste management, which are the basic fields of collecting and processing wastes effectively and efficiently, are different concepts. The main issue here is that the waste is a term with serious legal consequences. For example; Import of waste is forbidden. Reverse logistics focuses on products that have some value in order to be revaluable and their introduction into a new supply chain as output (De Britto & Dekker, 2002, p.4).

Waste reduction has become a prime concern in industrialized countries. For a variety of economic, environmental or legislative reasons, companies have become more accountable for final products, after they sell those products (Roghaniana & Pazhoheshfar, 2014, p.348). Waste management is a key process to protect the environment and conserve resources. In recent years, policies of governments towards waste management have focused on waste avoidance, reuse and recycling (Sbihi & Eglese, 2007, p.105).

Reverse Logistics and Closed Loop Supply Chain Management

The implementation of closed loop supply chain (CLSC) strategies enables companies to reduce negative environmental impacts of their business. In general, CLSC can be seen as the tradition forward supply chain supplemented by reverse operations for recovered products that are reprocessed and eventually reenter the forward supply chain (Stindt & Sahamie, 2014, p.271). For example, for copiers, where manufacturers or other companies within the distribution chain can directly reuse parts of the old machines or can remanufacture them. Thus supply chain transforms to closed loop supply chain (Schultmann et al., 2003, p.58).

The full CLSC includes (Blumberg, 2005, p.71);

- Forward logistics and direct supply chain management.
- Reverse logistics.
- Depot repair, processing, diagnostics, and disposal.

In essence, this strategic value of CLSC and reverse logistics management operations will have a very positive effect in terms of (Blumberg, 2005, p.78);

- Decrease in return costs.
- Increase value of recovered product.
- To provide the reliability, sustainability and dependability of the supported product and very important information on this subject.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Reducing shipping and storage costs of deliveries under small packages and reducing the period of partial or complete liquidation.
- It can be counted as fully automatic and fully controlled recycling process.

Benefits of Reverse Logistics to Companies

Retailers who adopt a more "consumer-friendly" approach to return policies provide higher levels of service to their permanent customers, thereby increasing customer satisfaction with high sales and profitability goals. Service failure; Customer satisfaction, customer loyalty, quality of service, trust and behavioral intentions lead to negative progress. For this reason operating effective reverse logistics programs is a critical part of retail business. Because in recycling activities that originate from a service failure, these programs often show the most visible and possibly last endeavor of the company (Horvath et al., 2005, p.191-2).

Implementing reverse logistics programs to reduce, reuse, and recycle wastes from distribution and other processes produces tangible and intangible value and can lead to better corporate image (Srivastava, 2008, p.538). For example; Nike, the shoe manufacturer encourages consumers to bring their used shoes to the store where they had purchased them after their usage. They ship these back to Nike plant where these are shredded and made into basketball courts and running tracks. Nike also donates the material to the basketball courts and donates fund for building and maintaining these courts, thus enhancing the value of brand (Ravi et al., 2005, p.332). Also these activities are a marketing incentive to purchase their products (Rogers & Tibben-Lembke, 1998, p.24).

Returned products can be classified as used long life-cycle products, used short life-cycle products, new established products and new innovative products. Table 2 shows the opportunities that will be provided to the companies in case the products in these criteria are returned (Avitatthur ve Shah, 2004, p.86-88).

Source: (Avitatthur, Shah, 2004)

New Established Products

Established products are ones that have been in the market for some time while innovative products are ones launched in the market very recently. Through previous experience and word-of-mouth, customers are generally well aware of established products. The returns for established products are mostly due to

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

product failure or other quality problems. Hence, the potential for product returns soon after purchase is low for established products.

New Innovative Products

Innovative products have a high product returns potential. So even if a new product has a large market potential, most of the potential customers are likely to be risk averse and would hesitate to buy the product. Many new technology products like the cell phone set, digital camera and DVD player fall in this category. Fashion goods like garments and sun glasses also fall in this category. The returns for innovative products could also be from retailers if the product has a short life in the market. If remanufactured products are sent back to the primary market, the reverse supply chain network originates at the customer and ends at the firm. If remanufactured products are directed to a secondary market, the reverse supply chain network originates at the customer, passes through the firm and ends in the secondary market.

Used Long Life-Cycle Products

Long life-cycle products are products that have high durability and little change in product design. such products are owned for long time durations. Household goods like ceiling fans and steel almirahs are examples of long life-cycle products. The potential of used product returns is low for such products. Creating reverse supply chains is least attractive for used product returns of long life-cycle products. Moreover, the usage of the product for a long period vastly reduces the potential of restoring it through remanufacturing to the same quality as that of a newly manufactured product. Hence, such products have limited scope for reuse and as a source of raw material.

Used Short Life-Cycle Products

Product returns of used short life-cycle products hold immense business opportunities especially for developing nations. Newer and better versions of these products get launched on a continuous basis, which motivates the customer to keep upgrading at regular time intervals. Products such as televisions, refrigerators and automobiles, even though used for some years, can be restored to very good working condition through remanufacturing. Products such as computers get obsolete within a few years but are still in working condition that is almost as good as at the time of purchase. Products such as floor carpets deteriorate after some time and have to be replaced. The potential for disposal by the customer is high for such products.

E-RETAILING

Since the beginning of the 2000s, there has been a significant increase in the use of the inte#rnet. This development is also reflected in the commercial life, and in particular, consumer electronic commerce has become a major and important segment of the new digital economy.

The retail sector is a sector that has emerged in the last two centuries. The first fabric store is R.H. It was opened in 1858 by Macy. In 1930, Marshall Field opened the first department store in Illinois (Nardal & Şahin, 2011, p.191).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Shopping from the internet has emerged as one of the most popular internet applications. In the beginning, although sales of durable items such as books outside the food were the sales center, nowadays, almost every product can be sold online (Bourlakis et al., 2008, p.64).

E-retailing is an important trade channel without distances between products and consumers (Nardal & Şahin, 2011, p.190).

The rapid development of information technology and internet presents the retailers with the opportunities for expansion to new online segments. The increase of users' purchase power and the combination of online consumption habit and the forms of mobile and social online shopping promote the growth of online retail market (Chen et al., 2014, p.261).

In parallel with the increasing use of the Internet, e-retailing sector is also growing. Besides;

- Consumers can shop at anytime.
- Consumers have access to products not available in their geographic region.
- An increase in high-speed internet access connections.
- Lower connection costs.
- Increasing consumer competence, e-commerce activity will continue to grow as the availability and ease with which the Internet provides consumers the ability to handle needed tasks increasingly develops (Changchit, 2006, p.177).

The young generation is passionate about e-retailing because they feel the benefits such as (Subramanian et al., 2014, p.70):

- Convenience
- Time saving
- A good deal of product information
- Door to door services
- 24–7 services

An e-retailing research report commissioned by the Goodman Group states that online shopping now accounts for almost a fifth of all purchases in developed markets and is growing at a rate of 15–20% a year (Yang et al., 2014, p.5382).

Consumers can visit e-retailers not only to buy products and services but also to gather information and even browse (Altuğ & Özhan, 2012, p.2).

The results of the research conducted by the Nielsen Research Company on 30,000 Internet users in 60 countries in 2014 are shown in Table 3. According to the table, people between the ages of 21-34, referred to as "Millennials", are the most frequent visitors of e-retailers and the most frequent online shopping group. The most important reason for this result is the fact that people belonging to " Millennials" came to the world in the era of information. Based on this conclusion, it can be interpreted that online shopping will include people called as "Baby Boomers" who are between the ages of 50-64 and in the following years online shopping will include people over the age of 65 called as "Silent Generation". Thus, as the "Millennials" grows, the increase in the volume of shopping made in electronic environment and the expansion of the products sold will be seen.

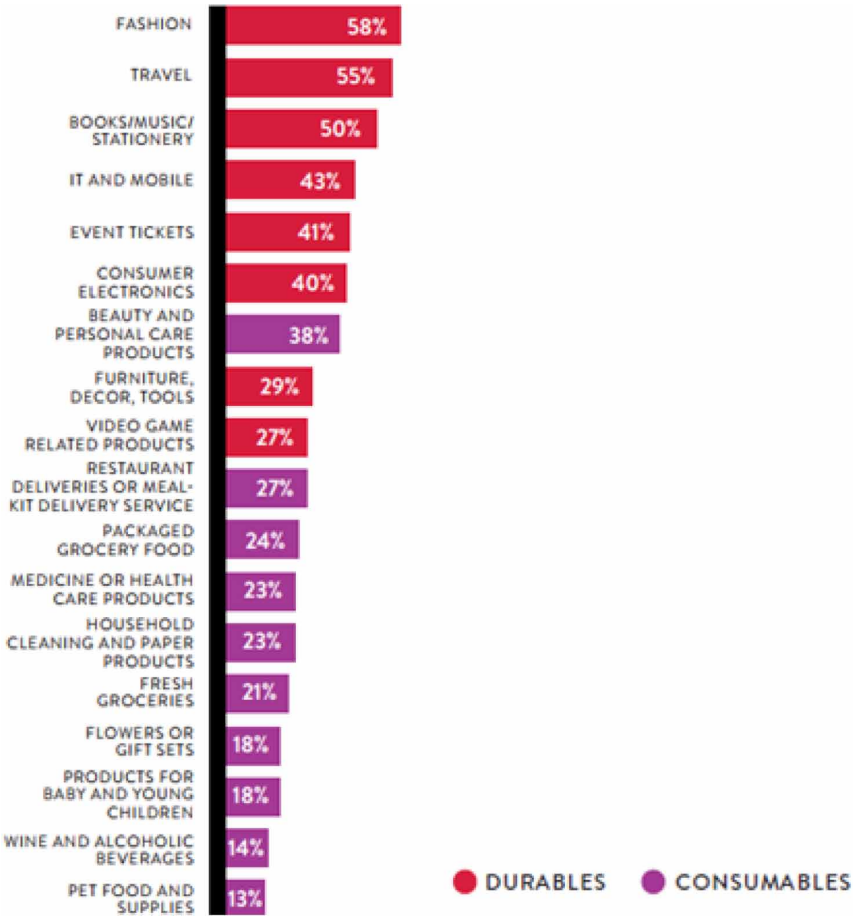
Table 3. Global average percent of the population ranges that make up online purchase intenders

	Will Browse Online	Will Buy Online
Generation Z (under 20)	6-9%	5-9%
Millennials (Generation Y) (21-34)	49-59%	52-63%
Generation X (35-49)	25-28%	25-30%
Baby Boomers (50-64)	7-13%	6-13%
Silent Generation (65+)	1-3%	1-3%

Source: (Nielsen, 2014)

As internet usage is increasing, so is online shopping, especially in those countries whose marketing infrastructures are well developed. Consumers can shop at anytime and have access to products not available in their geographic region. Furthermore, they are now able to access the Internet, not only from their personal computers, but from advanced electronic devices such as PalmPilots and mobile phones (Changchit, 2006, p.177).

Figure 3. Online purchase rates for categories
Source: *(Nielsen, 2017)*



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Durable and service-oriented categories form the baseline of entry for e-commerce, and their popularity continues to expand. More than half of global respondents in the online study say they've purchased fashion products (58%) or travel products or services (55%) online, and half say they've purchased books, music or stationery.

Consumable categories, in contrast, have been slower to gain popularity among online shoppers, but that is changing-especially for categories that are filling particular need states exceptionally well. In fact, nearly four in 10 global respondents (38%) say they've purchased personal-care and beauty products online, and about onefourth say they've ordered meal-kit or restaurant delivery services (27%) or packaged grocery food (24%) online. (Nielsen, 2017, p.5).

Information Which Must Be Shared With Consumers in E-Retailing

Retailers selling in electronic environment must inform consumers about business, product, sales process, contract conditions, storage of personal information, solution process to be applied in case of disagreement. The information provided must be accurate and valid (Svantesson & Clarke, 2010, p.33-35).

Information About The E-Retailer

Sometimes e-retailing is an appropriate environment for internet scams. An electronics store with a professional look can be created, managed, moved and removed within a few hours. For this reason, consumers need some information to be able to trust e-retailers. E-retailers should at least provide the following information regarding the safety of consumers:

- Information about the identity of the e-retailer.
- Information on where the e-retailer is registered.
- Information on the physical location of the e-retailer.
- All contact information of the e-retailer, including physical address, mailing address, e-mail address and phone number.

Information About The Product

Because consumers need some information in order to be able to evaluate the characteristics, quality and price of the products, companies should share the following information with their customers:

- In addition to service and maintenance information, a correct, appropriate and detailed description of the product, product specifications, use, limitations (eg, geographical restrictions on use, etc.).
- Information about after-sales service provided by the vendor, manufacturer or third party
- Information on the total cost of the product, including related taxes and surcharges (such as delivery costs).
- Breakdown of all costs.
- The functional currency.
- Information about warranties and guarantees.
- Information about safety.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Information About The Sales Process

While it may be easy to order a particular product, it can be very difficult for a consumer to understand the rules about the sales process. For this reason, e-retailers should work to provide a streamlined sales process that will enable consumers to fulfill their orders as easily as possible. For the protection of the e-consumer, the e-retailer should at least provide the following information about the sales process:

- Information on estimated delivery time and method.
- Information on current order tracking system.
- Information about the payment process.
- Information about revocation, change and return policies as well as the right to revoke or withdraw.
- Information on what to look for in credit card statements in case of sales by credit card.
- Information on security measures for shopping.

Information About The Terms of The Contract

Studies show that few consumers ever take the time to read the terms and conditions they agree to when entering into contracts online. For example, in one such study 90% of the respondents indicated that they never read the whole agreement, while at the same time 64% indicated that they always click ''I agree''. Furthermore, 55% did not believe that they entered into a legally binding contract when clicking ''I agree!''.

Businesses, including e-retailers, must provide easily accessible information about the terms and conditions of the contracts they sign. To protect consumers, the following information needs to be shared with consumers:

- The terms of the contract, expressed in clear and simple language.
- Information on how to negotiate the terms of the contract.
- Technical facilities for the protection of the terms (such as printing or downloading).

Information About How The Consumers' Personal Data Will Be Dealt With

The study of Lightner et al. (2002, p.378) on Turkish and American university students reveals that Turkish students have high anxiety about shopping safety when shopping on the internet.

Personal information of a consumer is an important source of commercial value. For this reason, e-retailers usually try to collect as many customers' personal information as possible. However, this creates a conflict with consumer privacy. E-retailers need to provide e-consumers with at least the following information:

- How to collect the data.
- What that data will be used for.
- Who can access the data.
- How to keep the data secure.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Information About Applicable Dispute Resolution

When few consumers decide to buy or not to buy a product, it considers the existence of a dispute resolution process. However, due to negative experiences consumers will revisit and customer loyalty will suffer greatly and victim consumers and consumer protection associations will try to find in the media the unfair behavior by e-retailers. Therefore, e-consumer protection schemes require e-retailers to share at least the following information about the dispute process:

- Limitations on the ways in which the consumer may apply for compensation, for example the binding of court provisions.
- Applicability of law.
- Provisions of arbitration.
- Options for mediation.
- Applicable internal/ external complaints systems.

Accuracy and Validity of Information

The information given above must be stated in the Consumer Protection Regulations which are valid both before and after the shopping. In addition, the consumer must be informed about how long this information is valid.

A consumer will have to read all the information at the beginning of every visit to the website unless they are certain that any changes have been made to the information. If an e-retailer shows the date of publication of the information it has made amendments, the consumer may evaluate the sections that need to be read again if they notice the changes. In case of a dispute, e-retailers need to store old information so that consumers can access it in the future.

Confirmation of The Transaction

Consumer protection regulation should require e-retailers to provide consumers with a prompt confirmation of the transaction as soon as an order has been placed. That confirmation should contain information acknowledging that the order has been accepted, information regarding expected delivery time and method used, as well as information regarding payment and applicable cancellation rights and procedures. Furthermore, the confirmation should be printable and possible to store in electronic form (for example, emailed at consumer's option or made available as a downloadable file).

Stages of E-Retailing Purchasing Process

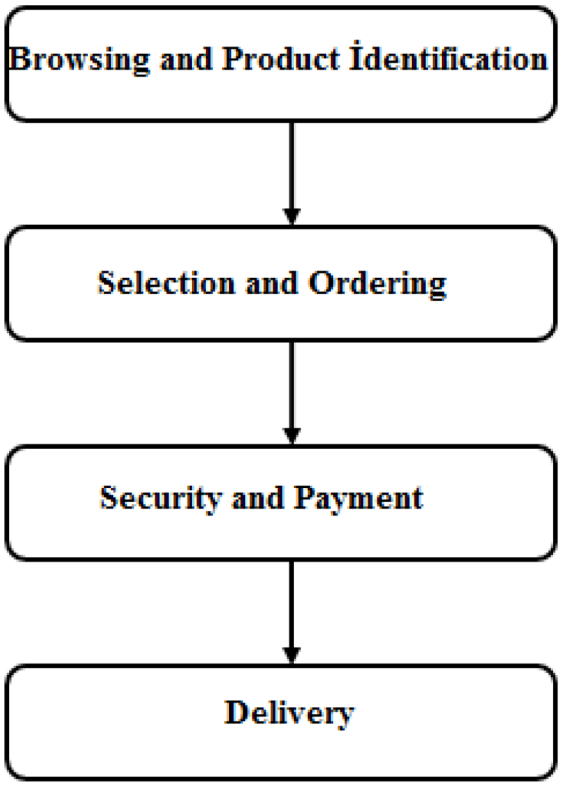
Rowley (1998), as seen in Figure 4, indicated that shopping on the internet occurred in four stages.

At the first stage, consumers are looking at the pages of e-retailers and examining the products. In the second stage, they decide which product to buy and place an order. The third stage consists of security and payment. The installment facilities offered to the consumer, different payment options, and the assurance that their information will not be shared with third parties in a safe manner will play an important role in the preference of the e-retailer. The final stage is to deliver the products to the consumer. The most

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

important steps for e-retailers in this process is to deliver security and products to consumers on time. Because the experience on the last two stages will affect the consumer's decision to resume shopping.

Figure 4. Stages of online purchasing process
Source: *(Rowley, 1998).*



According to Zhang et al. (2011, p.192) in general, online buying behavior can be understood in two stages: *the first stage* is primarily concerned with encouraging people to purchase online and *the second* is to encourage them to repurchase, which is critical if the e-commerce vendor is to succeed.

According to another research, the online purchase process involves three stages (Subramanian et al., 2014, p.70):

- **Pre-Sales Stage:** At this stage, while customers try to make a decision to select a specific e-retailer, e-retailers try to attract consumers by offering affordable products with good service.
- **Online Sales Stage:** During the online sales phase, customers make online purchases from e-retailers that provide ease of use and security.
- **Post Sales Stage:** In the last stage, e-retailers have to deliver products safely and help customers if there are any problems with the product.

As it seen, both customers and e-retailers have different roles and goals at different stages.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

High quality services at a low price, fast delivery of goods combined with enhanced website performance retain customers in e-retailing. Product characteristics (such as variety, quality and price), shopping experience (such as effectiveness, convenience and pleasure), customer service (such as responsiveness, assurance, reliability, tangibility and intangibility), and consumer risks (such as social risk, economic risk, performance risk, privacy risk and policy risk) ensure that e-retailers make a difference in the buying process. Additionally these factors affect consumer online purchasing behaviors; customers'perspective, e-retailers'reputation, other customers'comments or feedbacks and pre- and post-sales services (Subramanian et al., 2014, p.70).

Distribution Channels in E-Retailing

Physical stores are not always required to contact retailers and potential customers for logistics, to deliver products for payment. Distribution types in e-retailing; virtual retailers, brick and mortar retailers, and direct retailers (Dennis et al., 2004, p.206-7):

- **Virtual Retailers:** Only sell web-based products. Virtual retailers can do the retailing activities like; price and product comparisons and payment systems easier and quicker than physical retailers. The most known of virtual retailers, called "virtual retailers" or "pure play retailers" is Amazon, which started selling books on the internet in 1995.
- **Bricks and Mortar Retailers:** Is a name used to identify traditional retailers operating in the e-commerce environment with the establishment of virtual retailers. Bricks and mortar retailers have been given names to describe the physical store of the retailer. The biggest difference with virtual retailers is that the customers of bricks and mortar retailers have the chance to go to the physical store and check the product before purchasing the product.
- **Direct Retailers:** Offers a variety of distribution channels for consumers in the retail sector. As examples of direct distribution; Catalog marketing that has been used since the 1800s, door-to-door sales by Avon since 1960, telephone sales since 1970, and 24-hour shopping methods that have been in use since the 1980s.

Differences Between E-Retailing and Physical Retailing

Online shopping offers a variety of benefits to consumers, such as international accessibility, low costs, extensive information about the product, flexibility and convenience. On the other hand, the interaction between the seller and the customer in online shopping is in an uncertain environment, the confidentiality of personal information, the uncertainty of products and orders cause customers to perceive online shopping as more risky than traditional face-to-face shopping (Bulut, 2015, p.56).

According to Grewal et al. (2004, p.703-4), the difference between physical retailing formats and e-retailing is technology. Authors say that selling products such as jewelery, fine art works are much more difficult than selling in physical store because of the needs of trying, touching, tasting while buying them.

Hsiao (2009, p.89) says that economic and psychological differences between e-retailing and physical retailing are as shown in Table 4.

According to Turban et al. (2015, p.141-2), the differences between physical and electronic retailers are as follows:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Economic and psychological differences between store shopping and online shopping

Characteristics		
Attributes	**Store shopping**	**Online shopping**
Information Gathering/Shopping	• Travel cost	• No travel cost
	• Travel time	• No travel time
	o More shopping fun	o Less shopping fun
	o Less information uncertainty	o More information uncertainty
Purchase/Transaction	• Higher purchase price	• Lower purchase price
	o Less distrust feelings caused by transaction	o More distrust feelings caused by transaction
Delivery	• No waiting time for delivery	• Waiting time for delivery
	o Less inconvenience caused by delivery	o More inconvenience caused by delivery
	• Economic function	o Psychological function

Source: (Hsiao, 2009)

- **Customer Research Cost:** With today's shopping search and comparison engines and the use of mobile devices, the cost of customer research is much lower in e-retailing.
- **Delivery Time:** Physical stores, usually fulfil the order quickly. However, online companies are constantly reducing the time between purchase and consumption. In addition, some of the e-retailers have begun to develop distribution services on major metropolises the same day. Since the different stores sell similar products at similar prices, the delivery time has become a very important factor for e-retailers.
- **Delivery Costs:** Traditional retailers have to spend some money to build or rent a store, stock up, advertise a store, etc. On the other hand, e-retailers need to pay for packaging and shipment; Advertising and inventory costs are lower. These costs change depending on the products, geographical location and many other factors.
- **Tax Difference:** In many countries, the reduction in the amount of the tax applied to foreign online products is one of the advantages of e-retailing.
- **Price:** Not only online sellers but also "click and mortar" companies can offer lower prices for the same products.
- **Other Factors:** Consumers usually want to "touch and feel" before buying online. Especially young people prefer to go to a physical store to inspect the products and check the prices, and then buy the product with a lower price online. This is called "showrooming". In addition, shoppers can use apps on their mobile devices to compare prices. Recent shopping trends show that more people are shopping online and spending more money.

In addition, e-retailing offers flexible options for more efficient consumption of consumer needs (Torabi et al., 2015, p.130).

Despite these differences, many companies today are engaged in electronic retailing as well as physical retailing to expand their customer portfolio and retain existing customers. Most major retailers such as Wall-Mart, Tesco, and Sears are integrating electronic retail into their existing operations, especially since they have achieved sales volume (Nardal & Şahin, 2011, p.191). This type of firm is called "*brick and click*". *Brick* is the physical store, and *Click* is the online store. In recent years, such firms have

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

increased both at global and national scale. For example; companies like Mango, Zara, H&M operate in brick and click form.

Reverse Logistics and E-Retailing

There are businesses where reverse logistics is a part of the fabric of their organizations. For example, the mail order/catalogue companies can experience return rates on dispatched goods of up to 50 per cent, especially where fashion items are concerned (Rushton et al., 2010, p.598). According to recent industry reports, average return rates for products purchased online have reached levels as high as 22%. In contrast, product return rates average a more reason-able 8.1–8.7% for traditional retailers, according to 2013 reportsby the Retail Equation and the National Retail Federation (Rao et al., 2014, p.295).

Reverse logistics plays an important role in electronic commerce (Zuluaga, 2005, p.40). Reverse logistics activities in e-commerce applications are as shown in Table 5.

Table 5. Reverse logistics and e-commerce

E-Commerce Applications	Reverse Logistics Tasks
Marketing	• Advertisement of available used products, parts or material. • Notification of used products, parts or material, currently sought.
Purchasing	• Search for suppliers/customers • Making purchasing commitments • Receive information of expected delivery • Respond to request for sought used products, parts or materials
Sales	• Price setting (i.e. fixed, negotiations, auction • Order processing • Tracking and tracing orders • Customer invoicing, collection and payment
Post Sales / Service	• Product tracking • Customer support • Customer / product monitoring

Source: (Zuluaga, 2005)

In the shopping made from the internet, the products can not be seen closely, they can not be examined sufficiently, they can not be tried (especially in textile products) thus the number of returns increases. These returns cause both the retailer and the manufacturer to endure some costs.

Table 6 shows the direct and indirect costs of online returns in terms of retailers and producers. As seen in the table, customer dissatisfaction is an important cost item for both retailers and producers.

According to a report by Ryder (2010), over 13% of all HDTVs and 14% of all cellular phones are returned with well over half having no fault: again suggesting the incidence of retail borrowing. It is because of retail borrowing (one form of return fraud) that several retailers such as Target, Home Depot, and Saks have reassessed their return policies (Griffis et al., 2012, p.283).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Online return costs

Direct costs	Indirect costs
Retailer costs	
Lost consumer revenue	Lost bargaining power with suppliers
Original costs of bringing the product to the market	Negative impact on brand
Customer service costs	Weakened competitive advantage due to customer dissatisfaction
Processing costs for returns	Impact on customer lifetime value and switching costs
Increased inventory cycle time	
Manufacturer costs	
Lost revenue from retailers	Retailers frustrated with product returns processing
Processing costs for returns	Impact on customer lifetime value due to customer dissatisfaction
Increased inventory cycle time	Added burdens and distractions for logistics operations

Source: (Jayaraman, Ross, & Agarwal, 2008)

FUTURE RESEARCH DIRECTIONS

It has been seen that a large majority of studies on reverse logistics have been made for industrial consumers while literature review has been conducted.More academic publications on the reverse logistics processes for end users will be important for both consumers ' awareness and enterprises to develop themselves in this field.

CONCLUSION

Nowadays many consumers are biased towards online shopping. This bias prevents them from making purchases on the Internet (consumers do not shop in any way) or restrict them (they only purchase products that do not have the risk of returning them in terms of themselves. The increased number of brick and click style stores will be effective in the disappearance of this bias."Brick and click" style stores offer consumers more options than an e-retailer to return the product they buy.

As consumers can send the product that they want to return to the e-retailer via cargo, they can also return the product to the physical store.Thus, such stores will allow consumers to overcome the return process without a problem, and they will ensure the reverse logistics activities in e-retailing to be more active and customers to be more satisfied with this process. E-retailers' ability to manage the reverse logistics process will result in customer satisfaction. Satisfied customers will improve their revisit, repurchasing and loyalty behaviors towards that e-retailer and they will introduce their e-retailer with word-of-mouth.

ABSTRACT

In this chapter, the relationships between logistics operations and e-commerce are investigated. The logistics operations are discussed under the distribution and warehousing subjects. The effects of e-commerce on these activities are analyzed by considering the social, environmental, and economic dimensions of sustainability in a broad perspective. For evaluating distribution of e-commerce products, current last-mile operations, trends, and future expectations are investigated in the sustainability concept. Furthermore, the effects of e-commerce on warehouse types and operations are presented. Besides that, location and layout of warehouses, materials used in warehouse buildings, and material handling equipment are discussed with a sustainability perspective.

INTRODUCTION

In the last 50 years, the population of the world increased by almost 108% and the ten-year average population growth is almost 16%. (United Nations Department of Economic and Social Affairs, 2019) Since the borders of the world have evaporated by the effect of globalization and the widespread usage of the internet, the purchasing behavior of the consumers of the growing population has been chang-

ing rapidly in a global environment. Customers have begun to prefer purchasing from online stores to use their time more efficiently. This change and the global economy affected many industries such as manufacturing and lead to emerge new sectors such as e-commerce.

According to Lawrence et al. (1998) e-commerce is "buying and selling information, products, and services using any of the thousands of Internet computer networks". In 2019, worldwide e-commerce sales were US$ 3.53 trillion, and e-commerce revenues are forecasted to increase to US$ 6.54 trillion in 2022 (Clement, 2019). E-commerce retailing is growing 20% while the traditional retailing is growing 6% annually. However, e-commerce is still just a small part of the total €21 trillion retailing markets in the projection of 2019 (Laudon & Traver, 2016).

In the last decade, logistics has been greatly influenced by the growth of e-commerce. Logistics and cargo companies have been forced to change their operations and facilities to keep pace with the growth of e-commerce and to adopt new delivery services, delivery points and shorter delivery times. These firms have to provide various tailor-made solutions to meet their customers' fulfillment operations and last-mile delivery requirements. In the meantime, partial shipments and cargo shipments have increased. New distribution models for last-mile-delivery, have emerged. Customer demands are more various and in smaller sizes according to the past (Boysen, Fedtke, & Weidinger, 2018). Due to changing of customer order types, warehouse operations such as receiving, storing, picking and delivering and types have also changed. Fulfillment centers (FC) are established to meet the customers' changed expectations.

By e-commerce become widespread, consumers visit and shop from brick and mortar (B&M) stores less than before. Although consumers' movement has decreased (Mokhtarian, 2004), the transportation of goods that is triggered by e-commerce has increased all around the world. Increment of transportation level caused traffic congestions. Furthermore, it produces air pollution and noise. That means a decrease in life quality especially in the center of the cities. According to the U.S. Energy Information Administration Report on energy usage (2019), in 2018, about 28% of total U.S. energy consumption was due to transporting people and goods. Besides that, transportation is the largest producer of greenhouse gas emissions (GHG) with 29% in 2017 (Environmental Protection Agency, 2019). Warehouses also play a significant role in producing GHG. By air conditioning, lighting and material handling operations, warehouses produce 13% of supply chains GHG (World Economic Forum, 2009).

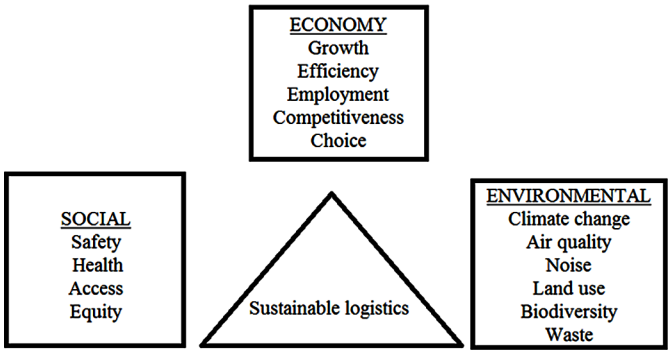
The effect of transportation on energy usage and carbon emission takes the attention of the researchers and leads them to focus on the issue from a sustainability perspective. Because it is a popular subject for the last three decades, sustainability has many definitions. One of the accepted definitions is "*development that meets the needs of the present without compromising the ability of future generations to meet their own needs*" (World Commission on Environment and Development., 1987). There are three major aspects of sustainability; environmental, economic and social.

Environmental sustainability is defined as "*a condition of balance, resilience, and interconnectedness that allows human society to satisfy its needs while neither exceeding the capacity of its supporting ecosystems to continue to regenerate the services necessary to meet those needs nor by our actions diminishing biological diversity*" by Morelli (2011). Environmental sustainability issues usually include GHG, air and water pollution, biodiversity, waste management, recycling, water consumption, energy consumption, usage of neutral resources, usage of renewable energy, environmentally-conscious customers and businesses, environmentally-friendly products, environmentally-friendly packaging. Economic sustainability is defined as "*maintenance of capital, or keeping capital intact*" (Goodland et al., 2002). Economic sustainability issues usually include global e-commerce sales and the percentage of e-commerce in gross domestic products (GDP) and the cost of products. McKenzie (2004) defines

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

social sustainability as "*a positive condition within communities, and a process within communities that can achieve that condition*". Social sustainability issues include unemployment, new employment areas, improved customer service level, quality of life standards, health and safety. The three aspects of sustainable logistics are given in Figure 1.

Figure 1. Three aspects of sustainable logistics
(Tambovcevs & Tambovceva, 2012)



While many of the studies about e-commerce logistics emphasize just environmental or economic aspects, only a few studies and industrial reports handle the subject on three dimensions of sustainability: economic, social and environmental. Furthermore, there is no study about e-commerce related to sustainability, associated with logistic operations in a broader perspective. Therefore, this chapter aims to evaluate logistics activities related to e-commerce in terms of three dimensions of sustainability. Furthermore, recently developed innovative solutions such as drone-based deliveries, usage of automated vehicles and automated warehouses, and best practices of the companies, supporting sustainable e-commerce logistics, will be discussed. The last but not the least, future expectations in the light of current developments will be presented in the following paragraphs.

The remain part of this paper is structured as follows. The next chapter discusses the e-commerce delivery and transportation trends and gives a brief explanation about how these trends affect sustainability. In the following chapter, the issues about warehouses that are necessary for e-commerce will be discussed with the perspective of social, environmental and economic dimensions of sustainability. Lastly, this chapter ends with the conclusion section.

SUSTAINABILITY EVALUATION OF E-COMMERCE DISTRIBUTION AND TRANSPORTATION TRENDS

Sustainable transportation is a very popular and studied subject. When we write "sustainable transportation" to the Google Search Engine, there are more than 1.1 million results listed (03.01.2020). For academic papers, Google Scholar lists 49 thousand results including this term. Too many results in the search show how much people use this term; can this also indicate that a sustainable transportation system

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

is being established today? According to Gordon (1995), people's behaviors, lifestyles, technology, and prices are changing those results in people gaining a vision of "sustainable transportation".

Sustainable transportation is a dynamic concept. While the population and human needs are growing, the meaning of "sustainable transportation" covers more issues every day. Is it impossible to reach a sustainable transportation system? Is "sustainable transportation" just a utopia? Even if the answer is "yes" for both questions, it is good to adopt the idea beyond the heading of Alberro's article, saying, "Utopia isn't just idealistic fantasy – it inspires people to change the world" (Alberro, 2019). From this point of view, it would be fitting for the very broad and widely accepted definition of sustainable transportation by the European Union Council of Ministers of Transport. According to the Council (2001), such a system

- "*allows the basic access and development needs of individuals, companies and societies to be met safely and in a manner consistent with human and ecosystem health, and promotes equity within and between successive generations;*
- *is affordable, operates fairly and efficiently, offers choice of transportation mode, and supports a competitive economy, as well as balanced regional development;*
- *limits emissions and waste within the planet's ability to absorb them, uses renewable resources at or below their rates of generation, and, uses nonrenewable resources at or below the rates of development of renewable substitutes while minimizing the impact on the use of land and the generation of noise.*"

Black (2010) gives a narrower definition of sustainable transportation on purpose because the author believes that, as the definition of sustainable transportation broadens, it cannot be achieved. According to this definition, sustainable transportation is a system, which provides transportation and mobility, using renewable fuels to minimize emissions and prevents transportation-related fatalities and injuries. Although sustainable transportation, defined by Black, seems to be achievable with relevant laws and policies, it does not adequately address the needs of this era.

Litman et al. (2007) proposed sustainable transportation system indicators. According to their study for the economic aspect, a sustainable transportation system is expected to serve efficient mobility, cause local economic development and reach operational efficiency. For the social aspect, this type of system is expected to ensure social equity, affordability, human safety and health, community cohesion, and cultural preservation. Besides, a sustainable transportation system is expected to reduce air, noise and water pollution and global warming emissions. Finally yet importantly, conserving resources, preserving open-space and protecting biodiversity are important performance indicators of a sustainable transportation system. The mentioned subjects above are generally accepted sustainability goals. How can one measure these goals? There are several indexes, aiming to measure the performances of sustainable transportation systems; Framework for Measuring Sustainable Regional Development (2010), Urban Sustainability Rating Tools (2014), Green Community Checklist (Environmental Protection Agency, 2015), etc. By reviewing several reports, Litman et al. (2007) recommends a list of indicators and classifies them into three groups; most important, helpful and specialized. According to them, most important indicators are personal mobility by mode, freight mobility by mode, land use density, total transportation expenditures, average freight transportation speed and reliability, average commute travel time and reliability and per capita congestion cost.

According to WHO (2019) respiratory and cardio diseases, cancer and many other diseases are associated with air pollution. Even adverse birth outcomes and premature deaths can be seen as a result

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of air pollution. WHO reported that, 3.7 million premature deaths are related to air pollution. The transportation industry is a substantial contributor to air pollution, which has a 24% share among all CO_2 emissions including freight and human movements. Especially for the freight sector, it is vital to decrease the amount of transportation-related emissions by using low carbon fuels, using more energy-efficient engines and delivering products more efficiently.

Widespread use of electrical vehicles seems like an environmental friendly solution but because of the high prices of such cars, firms generally continue to use gasoline-powered vehicles. The electric car sales rate increased by more than 2.5% in 2018. However, increased e-commerce sales and increased delivery within the time limits (same-day delivery, instant delivery) also increased the use of vans (IEA, 2019), which is a less energy-efficient option than large trucks (Bonilla, 2016). More than 250 European cities have adopted Low-Emission Zones (LEZ) and few cities have adopted Zero-emission Mobility Zones (ZEZ) since the Dieselgate scandal. The entrance of some road vehicles that have high toxic emissions to these zones is restricted. LEZ or ZEZ may have an accelerating effect on the wide usage of electrical vehicles by firms. In Madrid, after applying LEZ NO_2 concentration decreased 32%. Increasing rail investments and the rail usage rate (7% in 2019) is essential since the rail is an energy-efficient mode of transportation (Transport & Environment, 2019). Besides, promoting more sustainable delivery alternatives such as bicycle and walking deliveries and using crowdsourcing options are essential.

95% of the energy consumption of the transportation sector is based on fossil fuels and the rest is a combination of natural gas, electricity, and biofuels (Kahn Riberio et al., 2012). Because of the increasing number of gasoline-powered vehicles and increasing energy consumption rate due to rapid population growth, limited petroleum resources have become an important topic. According to the forecasts of the International Energy Agency (IEA), global energy demand will increase by approximately 42% from 2009 to 2035 (Singh, Avinash, & Agarwal, 2017). Diminishing petroleum reserves affects three aspects of sustainability. The social aspect of sustainability reveals the necessity of the fair distribution of scarce resources to current and future generations. From an environmental point of view, to fulfill the necessary energy need and to lower harmful emissions, cleaner and renewable energy sources should be produced and used widely instead of fossil fuels. Besides, dependence of petroleum creates an economic problem because of increasing crude oil prices.

From an environmental point of view, another essential subject of sustainable transportation is minimizing the effects of traffic noise. To be exposed to loud or continuous noise is dangerous for human health. It may cause psychological diseases such as annoyance and physiological diseases as ischaemic heart disease (WHO, 2019). According to a report (Jones, 2010), to be exposed to chronic aircraft noise has detrimental effects on memory, sustained attention, reading ability and understanding. Among children, this may cause a high degree of helplessness, motivational decrement and a higher degree of annoyance. Not just aircraft, also vans and motorcycles are noise sources in urban areas.

Because of limited parking areas in front of urban retail locations and restricted delivery times, drivers of delivery and pick-up vehicles park to illegal areas and this increases the number of parking violations. Walkability and bikeability performance indicators of social sustainability are negatively affected by parking violations. Also, double parking, seen on narrow and busy roads, causes congestion. Han et al. (2005) conclude that parking violations increase the travel time, number of accidents and transportation costs. According to research conducted by Mobility Lab and George Mason University, 73% of freight and delivery vehicles were used unauthorized areas to park in Arlington, which results in blocking sidewalks, fire hydrants or bike lanes (Hsu, 2019).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

With the rise of e-commerce sales, distribution strategies have changed. For an online shopping experiment, customers expect to reach products as soon as possible after placing an order. Delivering the right goods to the customer's place or a pre-determined place in the expected time is crucial for an online shopping experiment. Therefore, it is critical to design an efficient distribution network and to provide efficient and effective movement of goods for an e-commerce company (Huppertz, 1999). Because the success of an e-commerce company mostly depends on its delivery performance and distribution network. To meet customers' expectations regarding delivery speed same-day and instant delivery options are spread, the amount of motorcycle and bicycle deliveries are increased and new delivery options such as autonomous delivery robots were proposed.

Chopra and Meindl (2015) classifies distribution network design options into six categories, which are;

- Manufacturer stores the products and ships directly to customer (direct shipping),
- Manufacturer stores the products and ships to customer by in-transit merge,
- Retailer stores the products and customer pickups.
- Manufacturer/distributor stores the products and customer pickups,
- Distributor stores the products and sends them by package carrier,
- Distributor stores the products and uses last-mile delivery options (last-mile delivery),

Manufacturer storage with direct shipping or shipping after in-transit merge strategy is used frequently by e-commerce companies. For these options, the company sells products from its web site or application and send the products from its facility. This type of manufacturer is called a pure player (Rao, Goldsby, & Iyengar, 2009). Drop shippers may be added to this type of delivery network. In such a case, the manufacturer stores all inventory. After the drop shipper receives an order, information is relayed to the manufacturer and the manufacturer sends the product directly to the customer. If the manufacturer and the customers are distant, this distribution network results in long waiting times for the customers.

As the number of layers in a distribution network increases, customer response time decreases. If retailers and distributors participate in a distribution network then customers can reach products faster. Retailers or distributors store the products and customers can come to the stores and pick-up the products and send them to customers' places by using last-mile logistics (LML) strategies. Lim et al. (2018) classified these strategies into three groups: push, pull and hybrid. The push-centric strategy is a multilayer distribution system and requires picking up the products from the manufacturer's facility, distribution center (DC) or B&M store and delivering to the customer's houses or workplaces. Pull strategy requires the customer's involvement in the receiving stage of distribution. The customers receive physical products from local B&M stores and dematerialize products such as video games and software from information stores. The hybrid strategy combines push-centric and pull-centric strategies. In this strategy, the manufacturer or the distributor sends products to intermediate sites and customers pick-up products from these points. These delivery strategies and their effects on sustainable transportation will be discussed in the trends section.

E-Commerce Distribution Trends

Customers of an e-commerce company expect faster delivery, and this pressure forces B2C companies to chance their distribution networks. Especially the last-mile of the distribution networks, which end with customers reach their products, has to meet these expectations to stay competitive in the sector.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to Lim et al. (2018), last-mile delivery can be defined as "the last stretch of a B2C parcel delivery service, takes place from the order penetration point (factories, FCs, retail stores, etc.) to the final consignee's preferred destination point (recipients' doorsteps, collection delivery points (CDP) or pickup addresses, etc.)".

Last-mile delivery requires delivering myriad small posts to the multiple diverse locations within time limits. Due to these limitations, last-mile delivery (sometimes called final delivery) is the most expensive, inefficient and complex part of the supply chain management (Gevaers, Voorde, & Vanelslander, 2014). Especially e-commerce companies are willing to absorb last-mile delivery expenses to gain a competitive advantage even its costs exceed 50% of total shipping costs (Joerss, Schröder, Neuhaus, Klink, & Mann, 2016a).

With the rise of e-commerce, van usage for delivery operations has become widespread. Van usage has some negative effects on urban life quality. This delivery option increases the freight energy intensity, which can be interpreted as megajoules/tonne-km, and thus increase air pollution. Because of the limited capacities of vans and complex routes due to delivering small parcels to several points, this delivery method is highly cost. Vans are also effecting urban traffic congestion negatively, and this causes late deliveries, traffic violations, and accidents (Bonilla, 2016). Furthermore, human deaths or injuries due to car accidents are related to traffic congestion. According to research conducted by the U.S. Department of Transportation (2015), 94% of accidents are due to human errors and just in U.S. 4,761 people died in crashes that involve large trucks, in 2017.

To lower last mile costs and to make the delivery process more sustainable, many innovations are made by big players of the e-commerce sector (such as Amazon and Wal-Mart), academicians and startups. Some of these innovations are reception boxes (RB), click and collect points (C&C), drones, bike couriers, autonomous vehicles, crowd-sourcing logistics, anticipatory shipment, and underground delivery. Same-day, instant delivery or delivery with time windows options are becoming popular among customers. Furthermore, trucks, which can manufacture products by 3D printers, and mapping customer behavior to lower failed delivery rates by data mining are topical now.

Types of Delivery Points

If customers have to wait at home/office for their parcels to be delivered, this type of delivery is Attended Home Delivery (AHD). By using classical and most preferred (AHD) business model, costs of the last mile delivery may be up to 75% of total shipping costs (Gevaers, Voorde, & Vanelslander, 2009). In this option, courier brings the parcel to recipients' doorstep or office without a time limitation and if the recipient is not there at that time, then courier has to turn back there even two or three times by using road transportation, which causes more air pollution in urban areas, more traffic noise and more usage of transportation facilities. For the economic aspect, this kind of model leads to inefficient pricing because transportation companies do not know which product will turn back to their facility and how many visits will be conducted to the customers' home or office. Another disadvantage of this model is ringing a bell, waiting for the door to be opened and having customers' sign processes are time-consuming for both parties. Besides, setting time windows for customers results in complicated vehicle routes and more energy consumption.

Another delivery option is Unattended Delivery (UD), and this can be defined as delivering products to a specific place. According to Kamaranien et al. (2001) delivery cost can be reduced by up to 40% by using UD options in comparison with AHD. When considering the social point of view, AHD and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

some of the UD options are beneficial for people with disabilities, about accessibility to products. If retailers provide free shipping opportunities, these delivery options are also beneficial for people with lower incomes. By this opportunity, they can get their products without paying extra money and without using their cars.

UD options are RBs, delivery boxes and shared RBs (Hübner, Holzapfel, Kuhn, & Obermair, 2019). A reception box is a delivery point, which has generally a refrigerator and a freezer unit and provides foods to be stored at predetermined temperatures, generally used to deliver groceries. Wang et al. (2014) mention three kinds of RBs; independent reception box (IRB), delivery box (DB) and shared reception box (SRB). IRB is located at the house (home yard or garage) of the customer. DB is an insulated secured box with a locking mechanism and returns to the retailer. SRBs have separate lockers with changing opening codes and people living in apartment blocks or building complexes jointly can use them. By using RBs, parcels can be delivered even if the customer is not at home. If this box has a controlled access system, couriers may call the recipients and the customers can see the couriers from the camera and open RB by using their mobile phones. Other models of RBs generate specific codes for every delivery and the courier can open the box by using this code. Usage of RBs results with less failed deliveries (Punakivi, Yrjöla, & Holmström, 2001). Besides packages are not need to be sent twice, so energy consumption per freight ton-mile, climate change emissions, air and noise pollution are expected to be lower compared to classic AHD. However, among these alternatives, SRB is the most cost-effective, timesaving and environment-friendly option for delivering companies.

Another main type of delivery point is C&C. There are three categories of C&C points; pick-up point in store (PPS), pick-up point attached to a store (PPAS) and a solitary pick-up point at another location (SPP) (Hübner et al., 2019). A PPS is generally a temporary booth, placed inside the store. PPAS is similar to PPS but with one difference. In PPAS, the pick-up point is located outside the store and customers take their orders by drive-through opportunity. In both options, customers buy products online but they have to collect their orders by visiting the store. For customers, this will be a less time-consuming shopping experience but still, they have to go to the store and pick-up their orders. From the retailers' point of view, this option is less costly than sending the products to the customers' houses. In the SPP option, orders can be picked up by customers from a DC. This option requires a high set-up cost and increases logistics costs.

There are other delivery applications have been offered and implemented. As an example, Amazon offered in-car delivery service in 2018 that enables couriers finding customer's cars with "Key App", unlocking the trunk with keys and delivering products inside the trunk. This option also decreases the probability of failed delivery while increasing cost factors related to the delivery automation system (Reyes, Savelsbergh, & Toriello, 2017).

Delivering Within a Time Limit

Delivering products at a specific time, within a time windows, within same-day or instantly are becoming very common. Both e-commerce companies and parcel delivery services are offering these kinds of delivery options. These options are very costly but some customers are also ready to pay more for these kinds of services. According to research conducted in China, Germany, and the USA, 25% of respondents are willing to pay for same-day or instant delivery options. It is expected this share to increase due to the younger generation is keen on these options. By 2025, the share of same-day and instant delivery

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

options of the global e-commerce parcel delivery market are expected to reach 20% to 25% and may have a larger slice of pie if these options can be extended to rural areas (Joerss, Neuhaus, & Schröder, 2016b).

While orders with time constraints increased in number and constraints became definite, solving these kinds of problems requires more time and money. The solutions are getting complicated and this results in longer freight movement times. Boyer et al. (2005) illustrated the solutions of a delivery route problem with and without time windows and showed the effects of time windows constraint on route planning. According to their study, the solution of a 1-hour time window and no window had resulted in a decrease in more than 50% miles per customer. This kind of extra tours decrease the efficiency of the delivery process, increase cost, energy consumption per freight ton-mile, climate change emissions and air and noise pollution.

Crowdsourcing Logistics

Crowdsourcing is used for last-mile delivery by giving the delivery tasks to nonprofessional individuals from a network of people on a technological platform. These individuals generally provide this service by their vehicle and if the delivery point is on their route. This may be for free (Chen & Pan, 2015) or for a fee (Wang, Zhang, Liu, Shen, & Lee, 2016). Amazon, Instacart, Postmates, Shitpt and several other startups have adapted the "Uber Model" to product delivery services, especially for meal deliveries. While generally, these companies match the orders with the proper individuals within the system, Walmart uses a different and more environmentally friendly crowdsourcing strategy than an "Uber Model". It matches orders with its employees after work routes. Also in 2018, Walmart began to use "Spark Delivery" besides its current crowdsourcing model.

Uber Model services are not always cost-efficient especially in countries with high labor costs (Starcke, 2018). However, if people use existing transportation opportunities while they are going home/work, then this kind of transportation becomes cost-efficient and environmentally friendly. If the free capacity of citizens is used to carry loads, this will lead to a reduction in idle vehicle kilometers of vans (Rai, Verlinde, Merckx, & Macharis, 2017) and related pollutants. Employment level increases in the short term (Taylor, 2015); however, in the long term, when drones and AGV's become widely used, the unemployment level for these employees is expected to increase. Also, integrating public transportation based crowdsourcing models with shared reception box and parcel locker deliveries will provide sustainability advantages (Wang et al., 2016).

Automated Delivery Vehicles (ADVs) Usage for Distribution

The usage of ADVs for e-commerce logistics is one of the topical issues of the logistics industry. There are four types of ADVs; unmanned aerial vehicles (UAVs), sidewalk delivery robots, self-driving cars and automated delivery pods (Marks, 2019). These vehicles are on progress, but only some of them are officially in service. ADVs can be used to deliver meals, groceries and other packages. According to the report of McKinsey & Company (2016b), 85% of the parcels will be delivered by ADVs, by 2025, assuming that this technology and the service will become cheaper. If they don't become cheaper, then bicycle delivery is expected to be the best instant delivery option.

According to the simulation results of Gružauskas et al. (2018), transportation costs of distribution systems, work with autonomous vehicles, are 5% less than the traditional distribution systems. Besides, they indicate that the CO_2 emission level can be lowered by 22% by using autonomous vehicles. These

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

technologies are expected to make things easier especially for disabled and elderly people but also there are various concerns about human health. People will become immobile by using these kinds of technologies.

The smallest version of the ADVs are drones and they are already delivering in some regions of Australia (Porter, 2019), France and China. France's postal service has used this technology to deliver parcels to hard-to-reach Alpine villages (Willsher, 2019). Google's parent company Alphabet is using drones in Australia and their drone delivery system has just been approved by the US government. Amazon, Uber and other US companies are still waiting for the necessary legal permissions. By these permissions, Amazon Prime plans to deliver 80-90% of its deliveries by drones by 2030 (Spisak, 2019). They aim to carry up to 2.25 kg parcels per delivery within 30 minutes and under $1.

Especially for icy ridgeways and hard-to-reach areas, drone usage seems more reliable in comparison to delivering with vans (Boeras, Collins, & Peeling, 2019). Also by using drone deliveries, it is expected to reduce traffic and obstacles (Murray & Chu, 2015) and to lower carbon emissions using long-life rechargeable batteries. If Amazon Prime Air achieves drone usage goals by 2030, the number of trucks on the way will be reduced which also causes lower carbon emissions (Spisak, 2019). Besides the good sides of drone usage, there are many critical issues to be considered in the means of sustainability. The safety of drone usage is still an investigated research area. A small crash can be resulted by serious damages in the health of people or public infrastructures or airworthiness. According to DPD, drones have many features such as "anti-collision systems", "autonomous parachutes", flight recorders and cameras in case of emergent situations (Willsher, 2019). Another problem related to drone usage in deliveries is noise pollution. Even if the noise of trucks will be reduced by drones soon, drone-related noise pollution will be another critical issue. Another worrisome issue for the social aspect is privacy related to the usage of normal and infrared cameras, on drones. This may cause, collecting unauthorized images illegally.

Sidewalk robot usage in e-commerce deliveries will be an inescapable situation in the near future. Many models have been developed and tested by delivery companies such as Amazon and FedEx. Robots or droids are self-guided delivery vehicles, moving on a determined path (Slabinac, 2015). These are generally equipped with GPS, HD cameras and ultrasound sensors. Due to the high technology investment requirements of these robots, the costs of using robots are high. Unless they do not become more affordable, they have less chance to compete with cheaper delivery options especially in countries with cheaper labor costs.

Drones and sidewalk robots do not have negative effects on traffic congestion. However, unlike drones, these robots occupy a place in sidewalks. As the usage of sidewalk robots becomes widespread, pedestrian traffic in cities (walkability), especially with narrow sidewalks, will be affected negatively. In addition to pedestrians, wheelchair users and parents with strollers should also be taken into account while planning sidewalk robot delivery systems. While planning newly developing residential areas, sidewalk robot traffic can be considered; but for old settlements, it will be hard to adopt these robot delivery systems to existing sidewalks. For now, robots move on sidewalks slowly for safety concerns. Their speed is about 4-6 km/h and this slow movement gives robots the necessary time to think about the next steps and to move without crashing any object or people. For now, this type of delivery is available on some university campuses.

The use of vans and trucks is expected to decrease when ADVs and drones are widely used. However, in the short term, since the battery life of the current drones is short, they are expected to move with the vans. According to ADV producers, ADVs are expected to eliminate human-induced accidents by eliminating people from the transportation system. While it is expected that robots will help prevent

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

accidents caused by trucks and vans soon, it is not yet known whether it will reveal a new source of accidents called robot accidents.

SUSTAINABILITY EVALUATION OF E-COMMERCE WAREHOUSES

E-commerce is growing at a remarkable speed. According to Statistica (2019a), in 2019, worldwide e-commerce sales were $3.53 trillion and e-commerce sales are projected to rise to $6.54 trillion in 2022. Both in the United States and Europe, the sales of business to customer (B2C) e-commerce as a percentage of gross domestic product (GDP) have an increasing trend between 2009 and 2019 (Statistica, 2019b; 2019c). The expanding e-commerce requires larger regional warehouses and smaller urban warehouses in order to facilitate the movement of goods and meet customer needs in a shorter time (Deloitte, 2014). Especially in the business-to-customer (B2C) segment, the order sizes are getting smaller while the demand variety is increasing. The expected delivery times by the customers are getting shorter. Same-day delivery or even next day delivery became obligatory for the retailers. The survey, which is conducted by Peerless report group annually on behalf of Logistics Management for Honeywell Intelligrated shows that "on-time delivery" is the most significant key performance indicator with 49% for e-commerce retailers.

Growth in e-commerce retailing caused changes in the whole supply chain. One of the most affected parts of the supply chain is the warehouses. Traditional warehouses have difficulties to meet customer requirements on time and accurately so that the traditional picking systems in warehouses need to change. Especially picking operations need to be improved. The Peerless Report Group report explains that picking is the second biggest operation in need of change with 35% (Peerless Research Group, 2019). In order to facilitate the picking operations, automation, voice-directed picking systems or robotics become interest areas of retailing companies. In addition to the operations in warehouses, the warehouse types and sizes begin to change because of the new distribution networks that appeared due to expanded e-commerce (Öztürkoğlu, 2018). Besides the big DCs, FCs to serve e-commerce orders quickly and on time, are beginning to serve. (Peerless Research Group, 2019). According to the Bureau of Labor Statistics in the U.S., the number of warehouses reached 18.500 in 2019 from 17.000 in 2016 (United States Department of Labor, 2019). The changes in the warehouse industry due to e-commerce created many consequences in the social, environmental and economic dimensions of sustainability.

Although 51 thousand jobs were lost in the retail sector due to e-commerce, 355 thousand new jobs with FCs arise in the sector (Mandel, 2017). Amazon.com which is the top e-commerce retailing company in the world according to Forbes (Angelovska, 2019) works with more than 250 thousand employees in its 104 warehouses and FCs as of 2018 (National Bureau of Economic Research, 2017). Walmart.com which is in the top 5 e-commerce retailing company has 173 DCs with 125.8 million square feet (MWPL International Inc., 2019). The second-largest e-commerce retailer in China JingDong has 166 warehouses and 7 logistics centers (Yu, Wang, Zhong, & Huang, 2016). The average warehouse area in the United States increased by 143% between 2012 and 2017 (Bartolini, Bottani, & Eric, 2019). The growth in the amount and size of the warehouses, DCs, and FCs provide an opportunity for employment. Besides the contributions of warehouses on the social dimension of sustainability, they also have an environmental impact on sustainability such as energy consumption.

According to the U.S. Green building council (USGBC), buildings use 41% of the energy and 29% are used for transportation and 30% are used in the industry in U.S. (Kaplan, 2019). The UK Green Building Council has identified construction as one of the most GHG -intensive industries in the UK

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

with almost 50 percent (Dadhich, Genovese, Kumar, & Acquaye, 2015). UK energy policy is leading the construction industry to reduce energy usage in buildings with the target of zero-carbon (Rai, Sodagar, Fieldson, & Hu, 2011). The warehouses generate nearly 11% of the total GHG emissions, which are created by the logistics sector (Bartolini et al., 2019). The level of energy consumption and consequential emission are major indicators of environmental sustainability. Increasing social awareness about carbon and waste management forces companies to re-engineer their supply chain, especially towards sustainable warehouses. Contributions of green building practices, using green energy sources, using energy-efficient material handling equipment, operational strategies for shorter travel distances are main practices for a sustainable warehouse.

In the following sections, the issues about warehouses that are necessary for e-commerce will be discussed with the perspective of social, environmental and economic dimensions of sustainability. FCs as a new warehouse type, location of the warehouse, layout of the warehouse, building materials of the warehouse, the equipment used in the warehouses for material handling will be described in terms of sustainability by considering the relation with e-commerce. The current implications, precautions, recommendations for the warehouse industry will be explained to support sustainability.

Fulfillment Centers

The success of e-commerce depends on giving customers what they want, when and how they want with as possible as the lowest cost. This needs real-time fulfillment solutions. Fulfillment means picking and packing the products in very small quantities and shipping them by parcel carriers (Ricker and Kalakota, 2017). In e-commerce FCs as well as the main operations, attaching instruction manuals, leaflets, taking complaints, repairing returned products, gift packaging, maintenance, management of the e-shop archive, sending sales reports may be served (Kawa, 2017). The operations in a FC and a warehouse are not similar. The operations in warehouses are generally routine but in FCs are not. Since the products in a FC are various, the preparing procedure for shipment needs different processes. A FC can be used as a warehouse but a warehouse can not be used as a FC. In a warehouse, large quantity of products are stored and shipped, and especially Business to Business (B2B) transactions arise. Warehouses are proper places to store seasonal products. The products are stored in warehouses until they are required but in FCs, the inventory turnover rate is larger than warehouses and the cycle time of products is shorter than the products in warehouses. The traditional retailing companies find out it is not possible to provide home delivery service to their customers with their existing delivery network. In traditional warehouses, the picking list is fixed after the picker begins to travel. However, e-commerce demands may cause updates in picklists and routes, which is called dynamic order processing. Incoming urgent orders may be added to a current route if it is necessary and the route is updated (Boysen, De Koster, & Weidinger, 2018). One of the most important requirements of e-commerce quick response is provided by dynamic order processing in FCs. The retailing companies usually meet the customer requirements from FCs. The FCs are vital for new trends in e-commerce.

One of the newest trends in e-commerce is developing fulfillment cross border by reducing shipment costs. Another trend is same-day delivery that is provided only in selected cities. Full coverage of the country with same-day delivery service should be supported (Kawa, 2017). Warehouses do not serve an external customer while serving an external customer is the main focus of FCs. Warehouses simply store products to be used at a later date. FCs pick and pack orders and make sure they get into the hand of the customer on time. Timely replenishment is critical because customers do not tolerate out-of-stock

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

situations. Retailing companies may provide fulfillment services themselves or other 3PL service providers may provide fulfillment services. Catalog companies or store-based retailers such as Walmart and JCPenney also have their distribution and fulfillment networks but they ship various products in large quantities in contrary to internet retailers.

Consumers spend 1.2 billion hours on unpaid work like driving to B&M stores, finding a parking lot, traveling between aisles, payment and driving back home in the U.S.. Some of these unpaid works transformed to works in FCs such as picking, packing and driving trucks for delivery. That's why e-commerce creates new jobs. Unlike traditional warehouses, in FCs orders of each customer are prepared by the products that are gathered from various suppliers so that collecting products from many different suppliers and manufacturers, consolidating them, picking and packing according to the customer order are new works emerged due to e-commerce retailing. The number of e-commerce companies and FCs increased by 400,000 from 2007 to 2017 while 140,000 B&M retailing companies closed (Progressive Policy Institute, 2017).

FCs play a critical role in employment. E-commerce FCs employ more workers than traditional warehouses (Texas A&M Transportation Institute, 2017). In Amazon's FC in Kenosha, more than 2000 permanent and 1000 seasonal workers are employed. Amazon now operates about 104 FCs around the country with a space of 80 million square feet. The company increased the number of workers from 14,000 in 2007 to 180,000 in 2016 in the United States and most of them in FCs (Progressive Policy Institute, 2017). Just growth of Amazon alone made a huge contribution to the employment. Besides that, the companies that work as both e-commerce company and retailer, operates FCs. For example, Chewy.com an online pet supplier retailer opened its fifth FC and hired 700 workers. Walmart opened an e-commerce FC in 2017 in Florida and planned to hire 1,500 workers in 2018. Between 2007 and 2017, the e-commerce industry provided 132,000 jobs and the warehouse industry provided 273,000 jobs (Progressive Policy Institute, 2017). Furthermore, as e-commerce increases product returns increase. The returned products need to be processed in the FCs. A new employment field appears due to e-commerce (Delloite, 2014). In terms of income, the average weekly earnings are 31% higher in FCs than in B&M retail jobs in the same county (Progressive Policy Institute, 2017).

Consequently, FCs that are emerged due to expanding e-commerce make a considerable contribution to the social dimension of sustainability by providing new employment fields and high income. The economic impact of those centers will be explained in the building section in detail.

Location of the Warehouses

The pressure of shorter delivery time requirement forces especially online retailers to be closer to the consumer to gain market share. This need may be met with the increased number of larger regional hubs and smaller urban warehouses. Urban warehouses like FCs play a critical role in last-mile delivery services. In the meantime, regional DCs are still required with their large volumes.

Due to transportation cause 28% of total energy consumption of U.S. in 2018 (U.S. Energy Information Administration Report on Energy Usage, 2019) and cause 29% of total GHG emissions in 2017 (United States Environmental Protection Agency, 2019), the location of the warehouses and DCs are crucial in terms of sustainability in the long run. The location of the facility is decided once and during the lifetime of the facility, the costs due to transportation are beard. The companies prefer the DCs or warehouses located near city centers and close to the highway, freeway, airport, port, and railway to minimize their distribution costs (Kaplan, 2019). Reduction distances in transportation means also a

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

reduction in the level of GHG emission. On the other hand, getting closer to the city centers may create traffic congestion also air and noise pollution near city centers due to the vehicles that carry goods among warehouses and demand points. Therefore, the location of the warehouses, DCs, and FCs took the attention of the companies and researchers. Companies make network studies to evaluate their location of warehouses to move closer to ports or closer to customers to reduce transportation energy consumption and consequential emission (Napolitano, 2013). In facility location literature, there are many studies, which aim to select the best location alternative according to considered criteria. For example, Demirel, Demirel, & Kahraman (2010) investigated the best location of a logistics firm among four cities by considering the criteria related to costs, labor characteristics, infrastructure, and markets. Ashrafzadeh, Rafiei, Isfahani, & Zare (2015) analyzed four locations in Iran for the warehouse on behalf of the Entekhab industrial group by considering 15 criteria. These criteria are labor costs, transportation costs, handling costs, land cost, skilled labor, availability of labor force, land availability, climate, existence of transportation modes, telecommunication systems, quality and reliability of transportation modes, quality and reliability of utilities, proximity to customers, proximity to producer, lead times and responsiveness. These studies are not related to sustainability directly. They did not take into account energy consumption or GHG emissions but indirectly they contributed to the environmental dimension of sustainability because their common objective was reducing transportation and this result causes a reduction in energy consumption and emission of GHG. Besides that, there are studies that are related to sustainability directly. For example, Govindan, Garg, Gupta, & Jha (2016) assessed facility location in terms of the triple bottom line (3BTL) of sustainability. Raut, Narkhede, Gardas, & Raut (2017) aimed to select a strategic location of a sustainable warehouse in their study. They identified 11 crucial, sustainable selection criteria for the chemical industry warehouse and purposed the governmental policies and regulations, climatic conditions of the region and strategic location as the most significant three factors for sustainable warehouse location.

Besides that, many studies in literature aim to determine the optimal location of a warehouse. Gill and Ishaq Bhatti (2007) considered the product distribution cost and warehouse capital cost in selecting warehouse locations and allocating retailers. Li et al. (2008) purposed a model to determine the location of a DC by considering transport mode and carbon emission. As a conclusion, they claimed that, as the price of crude oil rises, the income of the entire supply chain and carbon emission also decline, while the number of DCs increases. Büyüksaatçi and Esnaf (2014) handled the facility location problem to minimize CO^2 emission level appeared due to the transportation between the facilities and customers. In terms of infrastructure, there are no additional costs like electricity, water pipes, and roads for the warehouses located near city centers. Furthermore, infrastructure costs reduce, as the buildings are located near city centers (Kaplan, 2019). To locate warehouses close to city centers is also important for employee perspective. The transportation of the employees gets easier to reach to work. Therefore, the selection of warehouse location is a strategic issue that has economic, environmental and social dimensions of the businesses (Tan, Ahmed, & Sundaram, 2009).

Layout of the Warehouses

In a typical warehouse, there are four major operations called, receiving, put-away, picking, and shipment (Bartholdi and Hackman, 2011). In unit load warehouses in which large amounts of goods picked up and put-away as a single object like in pallets without decomposing into small pieces (Tompkins, White, Bozer, & Tanchoco, 2003), the aforementioned four operation areas are usually seen. However, since

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the put-away and picking operations are done in the same area, three areas may be seen in practice. In warehouses in which piece or case picking operations are handled, there may be additional areas such as the replenishment area. The placement of the warehouse may change according to the type of products stored such as perishable, frozen foods or flammable chemicals. In such a warehouse, products may require special conditions. For instance, a product needs to be stored in a refrigerated area, or another one needs to be far away from a specific product. Therefore, placing the areas to maximize storage utilization and minimizing travel distance with the concern of providing healthy working conditions for employees is the major objective of warehouse layout problems. The layout of any facility is designed and built once so it is difficult to change but not impossible. It can be modified if necessary with additional costs.

Warehouse layout literature also includes the aisle design. Many studies investigate the number and design of aisles to decrease travel distance or increase warehouse space utilization. In traditional warehouses, the picking aisles are located parallel to each other while cross aisles are arranged perpendicular to the picking aisles. Gue and Meller (2009) proposed two new aisle layouts as an alternative to the traditional ones. They are "Flying-V" and "Fishbone designs". With these aisle designs, the researchers provide to decrease the single-command (travel between a pick-up and deposit (P&D) point and a single warehouse location that a worker store or retrieve a single product/pallet) travel distance 10% and 20% respectively according to the equivalent traditional warehouses. Gue, Ivanovic & Meller (2012) evaluated modified Flying-V and inverted Flying-V aisle designs for a warehouse with multiple P&Ds and provide less expected travel distance. Öztürkoğlu, Gue, & Meller (2012) proposed three new non-traditional aisle designs (Chevron, Leaf, and Butterfly) which have one, two and three angled cross aisles. All new designs are investigated from the perspective of both travel distance and storage utilization and among them Chevron is proposed as the most applicable one for the industry. Öztürkoğlu, Kocaman, & Gümüşoğlu (2018) examined the Chevron design in a multiple P&D point warehouse. Kocaman, Öztürkoğlu, & Gümüşoğlu (2019) searched best aisle layouts to minimize the expected single-command distance for a multiple P&D points warehouse which is used frequently in the industry. Besides that, many studies searched new aisle designs and analyzed their benefits in terms of picking time or travel distance which is indirectly affects the cost of picking operation (Öztürkoğlu, Gue and Meller, 2014; Öztürkoğlu, 2015; Öztürkoğlu and Hoşer, 2018; Öztürkoğlu and Hoşer, 2019a; Öztürkoğlu and Hoşer, 2019b). Common objectives of the mentioned studies are reducing the travel distances in a warehouse between a P&D point and any location. Reduction travel distances cause cost saving, less energy consumption, and less GHG emission. Thus, a well-designed layout of a warehouse contributes to the economic and environmental side of sustainability in long terms.

Boysen et al. (2019) explained warehousing systems that meet the four requirements of e-commerce. They are fulfilling (i) small order under (ii) large variety with (iii) a great time pressure and (iv) varying workloads. They define mixed-shelves storage systems as a good alternative for e-commerce warehouses if the warehouse space is adequate. Mixed-shelves storage is a storage system that stores the products scattered by breaking down unit loads into small units. The main goal of this storage system is reducing the distance between any point in the warehouse and the closest unit of each SKU. By this system, the non-value added travel distance of pickers reduce and shorter delivery time requirement of the customers can be met. In this kind of storage system, the picker needs Information Technology (IT) tools like barcode readers and pick by voice to find the closest product. Boysen et al. (2019) also purposed batching and zoning as a non-value added walking time reduction method. Batching is defined as picking the same units of different orders in one tour to reduce total traveling time and zoning means partitioning the warehouse into zones to make the picker's travel in smaller areas to find the product that they look for

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(De Koster, Le-Duc, & Roodbergen, 2007). Amazon uses batching, zoning and mixed-shelves storage systems to reduce non-value added traveling of pickers (Boysen et al., 2019).

Building of the Warehouses

The warehouse buildings are one of the major energy-consuming factors (Rai et al., 2011; Dadhich et al., 2015; Ürge-Vorsatz, Cabeza, Serrano, Barreneche, & Petrichenko, 2015) since they need energy both in the construction phase and during the lifetime of the facility. The buildings are responsible for 30% of the GHG emissions because of energy consumption (MacNaughton et al., 2017). Almost 30% of black carbon and 33% of halocarbon emissions arise from the building industry (Ürge-Vorsatz et al., 2015). The materials used for insulation, roof, walls, lighting and fan systems (which are explained in detail in the following paragraphs) in the construction phase play a critical role in energy consumption. Since it is difficult to change these systems after building is finished because of additional costs, it is very important to plan it carefully before the construction phase of the facilities. Even so, it is not impossible to transform but the additional costs affect the economies of companies negatively in the sustainability perspective.

Various green building standards lead buildings to reduce the consumption of energy, waste, and water. Leadership in Energy and Environmental Design (LEED) program which is founded by the U.S. Green Building Council (USGBC) in the United States is one of the most popular certification programs in the U.S.. The buildings certified by LEED consume 11% less water and 25% less energy and have 34% lower CO^2 emissions (Kaplan, 2019). In 2013, a new version of LEED is released specifically for construction of warehouses and DCs. LEED-certified buildings have prevented the release of 33MT of CO^2 into the atmosphere and avoided premature deaths in the United States between 172 and 405, in 2016 (MacNaughton et al., 2017). Similar to the LEED program, in Europe, the BREEAM standards (Building Research Establishment Environmental Assessment Method); in Asia, the Green Building Evaluation Label (GBEL), also known as China Three Star; In Australia, Green Star; in Japan, CASBEE (Comprehensive Assessment System for Building Environmental Efficiency), are founded. Totally, the World Green Building Council (World GBC) recognizes more than 40 rating tools for green building (MacNaughton et al., 2017). In 2017, 304 buildings in 17 different countries gained sustainable building certification (Prologis, 2017).

Green building practices reduce GHG emissions as well as other harmful air pollutants like particulate matter, sulfur dioxide and nitrogen oxides, all related to the combustion of fossil fuels for electricity and heat generation in buildings. As a conclusion, the benefits of green building practices that have not yet been quantified (MacNaughton et al., 2017) have social and environmental impacts on sustainability. In addition to green practices, there are energy-saving innovations that support sustainability.

Smart buildings are one of the last emerged developments for buildings. In smart buildings, devices are used to monitor the usage of electricity, gas, and water. The smart meters, which are replaced with gas, electric and water meters are recommended to use in buildings to analyze energy consumption and avoid unpredictable payments. The obtained data is then analyzed to identify the opportunities for energy and cost savings (Napolitano, 2013). Consumption monitoring is one of the most innovative techniques that help to manage energy consumption in the whole building and to understand their energy-related GHG emissions. Prologis reported a reduction in energy use by 8.9% and in emissions by 4% in 2017 according to the previous year. Solar panels on roofs should be set. Prologis (2017) added 10 megawatts

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of solar capacity (onto the roofs of medium-sized homes) to their portfolio in four countries. By the solar panels emissions-free energy is produced (Prologis, 2017).

Photovoltaic panels and wind generators are not cost-effective tools for energy generation but if they are supported by the government's incentives, they become a favorable energy source with low lifecycle emissions. To support the businesses to use renewable energy the regulations should be updated. For instance, in the UK many local authorities force the businesses to meet 10% of their requirements by renewable energy sources. According to the "Merton Rule," policy 350 tons of carbon in a year are saved (DHL, 2010). Combining innovative solutions and renewable energy usage in warehouses may cause 70% less CO^2 emission in a warehouse. (Prologis, 2017).

One of the recently emerged developments for sustainable buildings is net-zero building model which compensates every unit of consumed energy by generating a unit of energy. Pudleiner and Colton (2015) proposed a net-zero energy building design process in which external wall insulation, window properties, infiltration and natural ventilation, lighting, and equipment are considered as the parameters of the model. KSS Architect built a net-zero facility that meets the energy requirement of all campus by setting up a roof-mounted 1.2 megawatt PV panel (Napolitano, 2013).

Materials

Insulation avoids air transmission between indoor and outdoor. This provides a reduction in energy waste and thermal comfort for workers (MacNaughton et al., 2017). The paints, adhesives, wood products, sealants, and carpeting are important for air quality indoor. The material selection can save energy and reduce CO^2 emissions during the life of buildings (Rai et al., 2011). Using natural insulation materials like cork, wood fibre and sheep's wool are also preferable since they provide environmental impact. For instance, sheep's wool release almost 98% less CO^2 than polyurethane materials (European commission report on Science for environment policy, 2011). Improving the insulation of a building may cause a reduction in demanded energy for heating, ventilating and air conditioning (HVAC) by 6–15% and this reduction may lead a reduction in CO^2 emissions by 4–12% for a medium-size warehouse (Ries, Grosse, & Fichtinger, 2017).

Professionals, architects, and engineers should be encouraged to use natural materials in buildings. Using local materials such as soil, stone, and timber in buildings reduces the amount of energy used by up to 215% (Morel, Mesbah, Oggero, & Walker, 2001) so the materials used for roofs, walls, and floors of the buildings affect the sustainability in an environmental perspective. The European Commission Report on Science for Environment Policy (2011) recommends using local clays and renewable ingredients like straw in brick selection to use in walls. Timber cladding and hemcrete walling systems are suggested instead of steel wall systems. Timber cladding may save CO^2 approximately 18% according to steel. Hemcrete is a highly insulating material that can be used in roofs, walls, and floors of the buildings. Since hemcrete includes lime and cement in the binder, it can save CO^2 more than steel and timber cladding systems (Rai et al., 2011). Radhi (2010) proposed vinyl material in wall cladding systems since it reduces embodied CO^2 emissions more than stucco, masonry, aluminum.

The European Commission Report (2011) recommends using roof tiles out of concrete because it is better than the roof materials which are made of ceramic or fibre cement. Concrete tiles can save 42% energy according to ceramic roof tiles. Solar power panels can be used in the warehouse buildings as less expensive energy.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

On the floor of buildings, it is better to use quarry tiles instead of ceramic tiles. It causes saving 86% in energy and 66% in emission (European commission report on Science for environment policy, 2011). Rai et al., (2011) investigated the materials such as steel, concrete, and cladding systems and recommended to use different concrete types with 50% ground granulated blast furnace slug (GGBS) to support energy saving.

Buildings made of wooden materials reduce primary energy demand and they can be carbon neutral if the wood materials are recycled at the end of its life cycle. Other materials such as steel, aluminum, copper, glass and PVC should be re-used because manufacturing secondary steel by using scrap steels reduces emissions 74%, compared to manufacturing the same amount of primary steel. The buildings should be constructed by allowing disassembly at the end of its life and the materials which are disassembled like bolts should be re-used in another building (European commission report on Science for environment policy, 2011)

Lighting

According to the US Energy Information Administration Report on Energy Usage in Commercial Buildings (2016), with 17%, lighting is a major contributor to energy consumption. Also, Dadhich et al. (2015) explain electricity consumption for lighting and diesel consumption for handling operations done by forklifts are the top two reasons for carbon emissions in the warehouses. Cook and Sproul (2011) claimed that energy consumption can be reduced up to 73% by changes in insulation, sawtooth roof, selective glazing, natural ventilation, renewal of lamps, and lighting controls in warehouse buildings. Colicchia, Marchet, Melacini, & Perotti (2013) recommended adjustments in lighting and heating systems as the primary prevention for energy saving in warehouses. Replace old mercury discharge lamps with high-pressure sodium lamps will save 15% in energy costs or replace old-style 38 m (T12) tubular triphosphorous-coated fluorescent lamps with 26 m (T8) tubes will save 8% (McKinnon et al., 2015). For example, in Deutsche Post DHL warehouse changing T5 bulbs with TS bulbs saved 40% energy consumption (DHL, 2010). The world's top retailing company Walmart provides cost-saving $200 million annually just by changing the fluorescent lighting system with the LED one in its stores and parking lots (Reagan, 2018).

Three options for warehouse lighting, high-intensity discharge (HID), fluorescent, and LED have advantages and disadvantages compared to each other. HID lamps have the lowest initial cost but need a warm-up time before reaching full illumination level. Fluorescent lighting consumes energy less than HID lamps so they are more energy-efficient but they are affected by the heat of the warehouse. If it is too cold or too hot, the lifespan of the fluorescent lighting gets shorten. The LED light is more energy-efficient than the other lighting systems and more durable than fluorescent lighting. Therefore, LED lights are the most appropriate lighting for warehouses (Davis, 2019).

In addition to the changing bulbs, using lights just when it is necessary is recommended (DHL, 2010) also using motion detectors and photo sensors should be used to turn lights on and off to avoid waste (Dadhich et al., 2015). Adding a motion sensor to the lighting design can reduce the cost of wasted energy almost 30% in large buildings like warehouses (Davis, 2019). According to Ries et al. (2017), replacing the standard incandescent lamps to fluorescents or LEDs may reduce demanded energy by 80% to 90% and consequently, emissions may decrease between 20 and 34% in the warehouses. Moreover, regular cleaning of light bulbs is recommended. Accumulated dust on bulbs in two years reduce the luminosity 50% and increase operational cost 15% (DHL, 2010).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The utilization of daylight is also an important issue for lighting. It should be considered in the construction phase of a facility (DHL, 2010). LED lighting, daylight tubes (solar tubes) are tools that reflect outside light inside. In this way, artificial lighting usage reduces. Furthermore, innovative solutions like Smart Meter, digitalSTROM or Kiwigrid should be used to monitor energy and carbon footprinting systems (DHL, 2010).

Heating, Ventilating and Air Conditioning (HVAC)

Operational energy, which is consumed for heating, cooling, ventilating, lighting and powering equipment, is the major component of building energy consumption during its life-cycle. According to the US Energy Information Administration Report on Energy Usage in Commercial Buildings (2016), ventilation and cooling consume 16 and 15% of the energy, respectively. According to the Freis, Vohlidka, & Gunthner (2016), heating and cooling system need most of the energy in a manual warehouse while the material handling equipment needs in a semi and fully automated warehouses. Dadhich et al. (2015) show that reducing the temperature of warehouse 1°C causes 10% energy saving.

There are many ways to reduce costs and emissions related to HVAC. To control the temperature of the warehouse, sensors should be used and to avoid heat loss fast-moving doors or barriers should be used. In this way, the stored goods may be kept in the required conditions. The required temperature of warehouse change according to the products stored. The products like frozen meat need to be stored -10°C, consumer goods need to be stored in 20 °C. The temperature of the indoor environment should also be set according to the working activities. In areas where hard physical activities exist like loading and unloading areas 13°C, in storage areas for dry products 10°C and in picking or inspection areas 19°C may be appropriate (McKinnon et al., 2015).

Indoor environment conditions in terms of HVAC and lighting are also crucial for workers. International WELL Building Institute gives significance to the health and wellbeing of the workers because they believe that higher conscious-workers in green buildings increase productivity. In the Harvard School of Public Health study (MacNaughton et al., 2017) 109 workers are exposed to working conditions in traditional and green buildings and a cognitive examination of higher-order decision-making ability is used to assess the workers. The results of the study show cognitive function scores of workers in green-certified buildings are better with 26.4%, according to the scores of workers in traditional buildings. Another study that investigates the effect of green buildings on the health of workers shows there are benefits providing fewer symptoms of sick building, asthma hospitalizations and lower death rates (Allen et al., 2015). In addition to the effect on health, green buildings have a positive impact on the productivity of the workers (MacNaughton et al., 2017).

The required temperature of the warehouses is maintained by the ventilation. The level of air changes means heat loss. It can be prevented by using fast-acting doors, which are opened if necessary and closed quickly, using zone-controlled thermostats. The heat source depends on the size of the warehouse. In large warehouses, the heating systems usually powered by fuel oil or gas. Heating in small warehouses is provided by warm air or radiant heaters or powered by gas or fuel oil (McKinnon et al., 2015).

Material Handling

In traditional warehouses, the products in the list of a customer order are picked by pickers by traveling between aisles and shelves. This type of picking is called picker-to-parts system. Almost 80% of the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

warehouses use the picker-to-parts system in Western Europe (De Koster et al., 2007). In picker-to-part system warehouses, forklifts, reach, and turret trucks are the most widely used handling equipment. They use a combustion engine that needs diesel, LPG or natural gas or powered by electricity.

According to Collom (2018), electric forklift provides less noise. This provides easier communication between employees and a good working environment for employees. Many studies compare that equipment in terms of environmental impact. Fuc et al. (2016) showed that electric forklift has a significantly smaller environmental effect than any forklift powered by an internal combustion engine (liquefied petroleum gas and diesel forklifts). On the other hand, some studies claim LPG forklifts performs better than electric forklifts in terms of environmental aspect. For example, Johnson (2008) showed that electric and LPG forklifts emit an equal amount of carbon theoretically, but in practice, LPG's have less carbon footprint than electricity. Facchini et al. (2016) show electric forklifts are environmentally preferable if the load is less than 3000 kg. While the weight of load increase the LPG forklifts become more preferable. The main disadvantage of electric forklifts is battery charging. Lead-acid batteries are used in battery-powered forklifts. The batteries may provide power for 8 hours. Changing battery takes almost 5-15 minutes in an automatic change out and it takes at least 45 minutes in a manual change out. A forklift that is charged during 8 hours needs an additional 8 hours for cooling. Therefore, an operation needs three batteries for each forklift in a 7/24 hour working environment. Since oxygen and hydrogen gasses are released in the charging duration it must be done in a temperature-controlled environment. In case of acid leakage in charging duration, the charging must be done in a reserved area and if it happens, the acid must be removed from the batteries for battery efficiency. The productivity of battery-powered forklifts may decrease while it is working. In order to reduce the decline in productivity, AC motors are recommended instead of direct current motors by EPRI (2004). As an alternative to the fossil fuel and battery-powered forklifts, fuel cell forklifts, which is designed as a hybrid system, may be used in warehouses. Fuel cell forklifts are more productive than battery-powered forklifts since they don't need time for battery changing, they can be refueled in five minutes, and it is more preferable in terms of environment since acid leakage does not arise. Although fuel cell forklifts have a high initial cost, they cause less total cost.

In addition, there are literature studies that investigate and compare efficiency of traditional equipment. For instance, Öztürkoğlu (2016) compared picking time of pallets with and without raisable turntable and showed using raisable turntable cause saving on picking time of pallets in warehouse. Since picking time reduction may cause increment in total number of picking operation in a specific period, unit cost of picking in this specific period may decrease. Therefore, it is possible that reduction in picking time can cause indirectly saving in cost of picking.

Automated Storage and Retrieval Systems (AS/RS)

The AS/RS is one of the most used material handling systems in warehouses. In AS/RS, the cranes handle unit loads by traveling vertically and horizontally at the same time. It is used for both unit loads such as pallets and totes and small units. AS/RS is usually used with equally sized rack systems. Lee, Lee, & Hur (2005) proposed an AS/RS with modular sized rack systems to meet the customer's various sized order types. As an alternative to the AS/RS, autonomous vehicle storage and retrieval systems (AVS/RSs) are proposed by considering the economic and environmental dimension of it. In AVS/RS, the unit loads are handling horizontally by vehicles and while vertical movement is provided by lifts. Many of the studies about handling systems showed that AVS/RS is much more suitable than AS/RS for

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

unit loads in economic comparison. Tappia, Marchet, Melacini, & Perotti (2015) showed that AVS/RS is more preferable in case required handling capacity is higher than the required number of storage locations and AS/RS is more preferable in vice versa. The environmental impact of the automated warehouse is assessed by the indirect CO^2 emission resulting from energy consumption. Tappia et al. (2015) also showed that CO^2 emission arises from energy consumption due to material handling operations during one year are lower in AVS/RS than AS/RS. For each 1000 single command cycle, AVS/RS consume 1.07 kWh energy and emit 0.39 kg CO^2 while AS/RS consume 9.76 kWh energy and emit 3.54 kg CO^2. There is not much research, which considers both economic and social dimension of sustainability simultaneously but Neto, Walther, Bloemhof, Van Nunen, & Spengler (2009) claimed that decreasing environmental effect is possible with cost increment so there is a trade-off between environment and economic dimensions of sustainability.

Automated Guided Vehicles (AGV) Usage in Warehouses

AGVs have benefits on the environmental dimension of sustainability by reducing energy consumption (Acciaro and Wilmsmeier, 2015) and emissions (Geerlings and Van Duin, 2011). AGVs generate less GHGs (CO^2 and NO^2) since they minimize travel distance (Schmidt, Meyer-Barlag, Eisel, Kolbe, & Appelrath, 2015). The AGVs are evaluated according to their energy usage by Schmidt et al. (2015) and battery-powered AGVs are more beneficial compared to diesel-powered AGVs.

The social contribution of AGVs on sustainability can be evaluated by the working condition improvements and working accidents. Between 1998 and 2007, 3 million work accidents came out and most of them occurred due to forklift drivers (Sabattini et al., 2013). AGVs have the potential to improve safety (Duffy, Wu, & Ng, 2003) in the working environment so this is a big contribution to the social side of sustainability. Krüger, Lien, & Verl (2009) explain the social and economic contribution of AGVs by presenting the reducing effect of AGVs and human corporations on lower back pain, spine injuries. Furthermore, the standards and regulations about the corporation of human and robot operators to improve their safety are examined (Kabe, Tanaka, Ikeda, & Sugimoto, 2010).

Although AGVs have high initial costs (Peterson and Michalek, 2013), they eliminate the labor cost (Gosavi and Grasman, 2009) and can reduce total handling costs. The top internet-based retailing company Amazon bought the manufacturer of Kiva robots that pick and carry a shelf of goods to a picker and used 30.000 kivas in its warehouses and FCs to decrease delivery times (DHL, 2016). By the time, they provide a high level of customer satisfaction that is one of the top expectations of e-commerce customers. Ventura and Rieksts (2009) generate a model to minimize the response time of multiple vehicles by providing on-time delivery in a shift. The AGVs contribution to the operational level promotes the economic dimension of sustainability.

FUTURE RESEARCH DIRECTIONS

In this study transportation, distribution and warehousing are evaluated as logistic activities. Although transportation subject is broad in scope, we investigated road transportation in the means of sustainability. It involves maritime, air, road, rail, pipeline and inland water transportation. Each mode of transportation associate with e-commerce can be evaluated in terms of sustainability in a new chapter as a future study.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

CONCLUSION

E-commerce is becoming widespread every day and this brings some challenges and benefits to the logistics world. Manufacturers, retailers and even small-scaled craftsmen can produce and sell their products using internet portals. Small parts can easily be sent to customers directly from a warehouse of a manufacturer via cargo companies. To deliver these small parts, lots of trucks and vans are on the move, which causes more CO^2 release every day. Due to e-commerce sales, last-mile distribution options are increased. While attended home delivery models increase van-miles and transport costs, unattended delivery (UD) options such as shared RBs, delivery boxes, C&C points provide environmentally and economically sustainable solutions. Instant delivery and same-day delivery options are becoming popular and time constraints make the distribution problems more complex. UD options also provide beneficial solutions for time windows constraints of customers and cause fewer van moves on the traffic. Even so, some UD options require customers to use their cars and pick up products from a specific place and this may result in more CO^2 release and traffic congestion. Crowdsourcing logistics has recently begun to use as a last-mile delivery option. These systems can be environmentally friendly and cost-effective if companies use already planned routes of workers or customers. New technologies such as sidewalk robots and drones are in use for delivering products. For now, these technologies are expensive and the effects of their common usage have not tested yet. The effects of such technologies should be evaluated in the means of environmental, economic and social aspects. Their permissions should be given locally, after evaluating the needs, the capacity and the characteristics of the related region.

Due to the changes in customer demand because of e-commerce, the FCs which provide customer orders on time and accurately are emerged in addition to the big regional warehouses. Beside the traditional equipment such as forklifts, reach trucks and turret trucks, automated systems to store and retrieve products and AGVs became widespread in the FCs. There are some advantages and disadvantages of this equipment about energy consumption, GHG emission rates, inventory cost and working environment of employees which are discussed above. Although all of these equipment have initial investment cost they provide benefit especially in terms of employees since they facilitate to lift heavy products. The equipment especially powered by electric and LPG is recommended in terms of environmental aspect. The issues such as location and layout of the facilities, materials used in wall, roof and floor systems, lighting systems, HVAC systems should be determined accurately before the facilities are built since they cause inventory costs, energy consumption and GHG emission. A brief summary of benefits emerged due to e-commerce related logistics issues that are highlighted in this chapter are shown in the Table 1.

Although there are many supply chain and logistics studies about sustainability in literature, many of them does not related to e-commerce or just one or two dimensions of sustainability has taken into account. The studies and industrial reports especially considered environmental and economic side of sustainability rather than social side. In this chapter, three dimensions of sustainability is considered while evaluating logistics activities, which are appeared due to, expanded e-commerce.

Table 1. Summary table of sustainability aspects and their benefits

Social Benefits Emerged Due to E-Commerce Related Logistic Issues	
Delivery and Transportation	**Warehousing**
· Easier reach to products with AHD and UD services (Cairns, 2007). · Reduction in idle vehicle kilometers of vans due to usage free capacity of citizens and workers as a part of crowdsourcing delivery (Rai et al., 2017). · Easier to reach products for disabled and elderly people by ADVs · More reliable deliveries to hard-to-reach areas due to drone usage (Boeras et al., 2019). · Reduction in traffic and obstacles is expected by using drones (Murray & Chu, 2015) sidewalk robots.	· Emerging of new jobs due to increased number of FCs and increase in employment (Mandel, 2017). · Reduction in unpaid work, which is transformed to work in FCs due to e-commerce (Progressive Policy Institute, 2017). · Easier reach to work for employees in warehouses/DCs/FCs, which are located closer to city centers with the aim of travel distance reduction between these facilities and e-commerce customers (Tan et al., 2009). · Reduction in sickness symptoms of workers like asthma in green buildings (Allen et al., 2015). · Better working conditions for employees in terms of air quality and noise through electric forklifts used in warehouses/DCs/FCs (Collom, 2018). · Reduction in accidents in warehouses/DCs/FCs through automated guided vehicles (Duffy et al., 2003).
Economic Benefits Emerged Due to E-Commerce Related Logistic Issues	
Delivery and Transportation	**Warehousing**
· Decrease in transportation costs due to increment in UD services (Kämäräinen et al., 2001). · Reduction in transportation cost due to usage free capacity of citizens and workers cars as a part of crowdsourcing delivery (Rai, 2017). · Reduction in transportation cost is expected in the future due to delivering with autonomous vehicles (Gružauskas et al., 2018).	· Reduction in travel distance between warehouses/DCs/FCs and e-commerce customers (Kaplan, 2019; Napolitano, 2013; Demirel et al., 2010; Raut, et al., 2017) and hence reduction in cost of transportation. · Reduction in travel distance between product locations in warehouses/DCs/FCs through new aisle layouts (Gue and Meller, 2009; Öztürkoğlu et al., 2012; Kocaman et al., 2019) and hence reduction in cost of transportation. · Reduction in travel distance through new storage systems in warehouses/DCs/FCs to pick products in an order list (Boysen et al., 2019) and hence reduction in cost of transportation. · Reduction in energy consumption by selecting appropriate light bulbs (Colicchia et al., 2013), by using them when necessary (DHL, 2010), by cleaning the bulbs regularly (DHL, 2010) and by using sensors to turn lights on and off (Dadhich et al., 2015; Davis, 2019) in the warehouse/DC/FC facilities. · Reduction in energy consumption by using sensors for HVAC and hence reduction in cost of warehousing (McKinnon et al., 2015). · Reduction in energy consumption by using AS/RS and AGVs in warehouses/DCs/FCs and hence reduction in cost of warehousing (Tappia et al., 2015; Schmidt et al., 2015). · Reduction in in energy consumption by utilizing day light more in warehouses/DCs/FCs (DHL, 2010).
Environmental Benefits Emerged Due to E-Commerce Related Logistic Issues	
Delivery and Transportation	**Warehousing**
· Reduction in GHG emissions due to increment in electrical vehicle usage (IEA, 2019). · Reduction in GHG emissions due to increment in ZEZ and LEZ (Transport & Environment, 2019). · Reduction traffic noise, air pollution and fuel-oil consumption due to usage free capacity of citizens and workers cars as a part of crowdsourcing delivery (Rai, 2017).	· Reduced energy consumption and GHG emissions due to green warehouse buildings (Kaplan, 2019). · Reduction in travel distance between warehouses/DCs/FCs and e-commerce customer and hence reduction in amount of GHG emissions (Napolitano, 2013). · Reduction in travel distance through new aisle layouts in a warehouse/DC/FC to pick products in order list (Gue and Meller, 2009; Öztürkoğlu et al., 2012; Kocaman et al., 2019) and hence reduction in amount of GHG emission. · Reduction in amount of GHG emission by using renewable energy in warehouse/DC/FC buildings (Prologis, 2017). · Reduction in energy consumption by using natural insulation materials for the wall, floor and roof of the warehouse/DC/FC buildings (MacNaughton et al., 2017; Rai et al., 2011). · Reduction in amount of GHS emissions by using electric forklifts in warehouses/DCs/FCs (Fuc et al., 2016).

Chapter 53
The Influence of Enjoyment Factor Toward the Acceptance of Social Commerce

Alaa M. Momani

ABSTRACT

Social commerce is a new extension of electronic commerce that involves using social media in the online shopping process. Although the adoption of social technologies was studied in several researches, it is still needed to investigate the specific characteristics of social commerce and the affecting factors on its acceptance. This article verifies the influence of the enjoyment factor on the adoption of social commerce through applying a questionnaire sample allocated to 282 Jordanian social media users from those who are interested in online shopping. The research model is developed to validate the impact of enjoyment, in addition to some other factors, on the behavioral intentions to adopt and use social commerce. The results show that the enjoyment is a key factor on accepting social commerce. The research model indicates that it is viable and has a good power in explaining the variance in the behavioral intentions to adopt and use social commerce.

1. INTRODUCTION

Social commerce (s-commerce) is a new stream in e-commerce, presented recently from the development of information and communication technologies (ICTs), Web 2.0 technology, and cloud technology. S-commerce represents the benefiting from the social networks to enhance the e-commerce by adding some new activities for the online shopping process, in order to make it more social and acceptable by users (Gatautis and Medziausiene, 2014). Some authors like Leitner and Grechenig (2007) and Liang, Ho, Li, and Turban (2011) believe that s-commerce is affected by the expansion of social networks. The research work of Hajli (2012) mentioned that s-commerce is the resent development in e-commerce that using social technologies in order to create a new environment for social interactions. These social interactions can push online social support in e-commerce, and increase the trust, and as a result, the intention to use s-commerce will be increased. In the s-commerce context, there were a few theoretical or empirical researches on the measurement of user satisfaction of the s-commerce, and measuring the success of such systems in general (Alshibly, 2014; Huang and Benyoucef, 2013). Accordingly, this study aims to investigate the influence of the enjoyment factor toward the acceptance of the s-commerce and the satisfaction from using it. It revised the unified theory of acceptance and use of technology (UTAUT) that was developed by Venkatesh, Morris, Davis, and Davis (2003) by adding the enjoyment factor in the form of enjoyment expectancy to the model′s structure in order to personalize it to be more suitable to measure the technology acceptance of s-commerce within the Jordanian society.

In general, the majority of the technology acceptance theories and models do not discuss the impact of the enjoyment factor on the behavioral intentions and usage behavior of the technology, because these theories were designed to explain the usage behavior and assess the acceptance of adopting information systems in organizations with the mandatory style of usage. S-commerce is a web-based, social-commercial, and voluntary-usage application, and the enjoyment is one of the key-reasons from using it.

2. LITERATURE REVIEW

Since 1940′s, many theories resulted from motivation research (Momani and Jamous, 2017). Self-Determination Theory (SDT) which developed by Deci and Ryan in 1985 is one of them. SDT proposed that self-determination is a human quality. Deci and Ryan (1985) and Ryan and Deci (2000a) explained the psychological innate human needs which are: autonomy, competence, and relatedness. These human needs are directly affecting on individuals′ motivations. The need to autonomy refers to self-determination that causes freedom of action, mainly being self-initiating, and to self-regulating one′s own actions. The need to relatedness refers to developing secure and satisfying connections with others in same social environment (de Brabander, Rozendaal, and Martens, 2009; Hsu and Lin, 2008). According to Deci et al. (1991), these needs are necessary for individuals to be self-determined rather than controlled.

Motivational theories have supported the researches in psychology as an explanation to behavior. These researches resulted that the motivational theory contains two major factors of motivations: extrinsic motivation and intrinsic motivation. Extrinsic motivation was defined as: “the perception that users will want to perform an activity because it is perceived to be instrumental in achieving valued outcomes that are distinct from the activity itself” (Davis, Bagozzi, and Warshaw, 1992, p 1112; Venkatesh et al., 2003, p 448). While Intrinsic motivation was defined as: “the perception that users will want to perform an activity for no apparent reinforcement other than the process of performing the activity per se”

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(Davis et al., 1992, p 1112; Venkatesh et al., 2003, p 456). SDT represents the extrinsic motivation that consists of four types of self-determinations, which are: external, introjected, identified, and integrated form of regulation (Deci and Ryan, 1985; Deci et al., 1991; Ryan and Deci, 2000b). While the intrinsic motivation refers to intrinsic regulation. It also represents how the social environment influencing on motivated behaviors. Davis et al. (1992) tested the extrinsic and intrinsic motivation to use technology in workplaces and found that they are key drivers of an individual′s intention to perform the behavior of technology usage. They explained the extrinsic motivation to use technology as perceived usefulness from using the technology, and intrinsic motivation to use technology as perceived enjoyment of using the technology (Ryan, Patrick, Deci, and Williams, 2008). They noted the relation between usefulness and enjoyment. Enjoyment strongly effects on intentions when information systems are perceived to be more useful, which means that the enjoyability of the information system is enhancing the acceptance of useful systems, but in the same time, it has less effect on acceptance of useless systems (Davis et al., 1992).

The same concept was discussed in several technology acceptance theories besides the motivational theory such as: Model of PC Utilization (MPCU) and Social Cognitive Theory (SCT). These theories are sharing the same features of intrinsic motivation in the motivational theory (Venkatesh et al., 2003). Shen and Eder (2011) examined the factors that influence the user acceptance of social shopping websites which are designed specifically to support social interactions with shoppers. Their study utilized the Technology Acceptance Model (TAM) with specific constructs that may enhance the power of the model to predict the user acceptance of social shopping applications, including social comparison, social engagement, enjoyment, perceived ease of use, and perceived usefulness. The study of Gatautis and Medziausiene (2014) aimed to address the users′ acceptance for s-commerce by identifying various factors affecting the attitudes towards its adoption. They reviewed the Theory of Reasoned Action (TRA), Theory of Planned Behavior (TPB), and TAM, and utilized the constructs of the UTAUT in addition to the factor of perceived enjoyment, as well.

3. RESEARCH METHODOLOGY

3.1. Research Hypotheses

The research hypotheses of this study present the relations between the model's constructs with the behavioral intentions and actual use behavior. All hypotheses of this research have to be tested statistically depending on the quantitative research method. The proposed research model of this study (Figure 1) consists of five constructs as follows: performance expectancy, effort expectancy, social influence, enjoyment expectancy, and facilitating conditions. The group of determinants (constructs) and their related proposed hypotheses are being discussed as follows:

1. **Performance Expectancy (PE):** It is defined as the degree to which an individual believes that using the system will help him/her to attain gains in job performance (Venkatesh et al., 2003, p 447). It focuses on testing the degree of the beliefs of users that using s-commerce in their online shopping activities will help them attain gains in their job performance. The related studies have shown that the performance expectancy has a positive and significant relation with the behavioral intention (Davis, Bagozzi, and Warshaw, 1989; Davis, 1986; Venkatesh and Davis, 2000). According to this, the following hypothesis was proposed:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H1: Performance expectancy has an effect on behavioral intention to adopt s-commerce.

2. **Effort Expectancy (EE):** It is the degree of ease associated with the use of the system (Venkatesh et al., 2003, p 450). It focuses on the degree of ease in using the s-commerce and social online shopping applications. The related studies have shown that the effort expectancy has a significant relation with the behavioral intention (Davis, 1986; Triandis, 1979; Venkatesh and Davis, 2000). According to this, the following hypothesis was proposed:
   H2: Effort expectancy has an effect on behavioral intention to adopt s-commerce.
3. **Social Influence (SI):** It is defined as: the degree to which an individual perceives that important others believe he/she should use the new system (Venkatesh et al., 2003, p 451). It examines the degree to what extent a consumer perceives that important others believe in using s-commerce. This determinant investigates the users′ opinion about the society influence on the decision to adopt s-commerce. According to this, the following hypothesis was proposed:
   H3: Social influence has an effect on behavioral intention to adopt s-commerce.
4. **Enjoyment Expectancy (EN):** According to Davis et al. (1992), the enjoyment expectancy is the extent to which the activity of using a certain technology is perceived as being enjoyable. Depending on the proposed framework of this study, enjoyment expectancy is proposed as a direct determinant of behavioral intention. This part of s-commerce acceptance focused on the hedonic experience that the consumer would gain from using s-commerce. This determinant tests the viewpoint of the level of enjoyment and fun expected from using the s-commerce. According to this, the following hypothesis was proposed:
   H4: Enjoyment expectancy has an effect on behavioral intention to adopt s-commerce.
5. **Facilitating Conditions (FC):** It is defined as: the degree to which an individual believes that an organizational and technical infrastructure exists to support use of the system (Venkatesh et al., 2003, p 453). It tests the degree to what extent a consumer believes that the social networks, as a working environment, support the use of s-commerce. The related researches denoted that it has insignificant effect on the behavioral intention. It has a positive influence on the usage behavior (Ajzen, 1985; Rogers, 1983, 2003; Taylor and Todd, 1995a, 1995c; Triandis, 1979). For this, the following hypothesis was proposed:
   H5: Facilitating conditions has an effect on actual use behavior of s-commerce.
6. **Behavioral Intention (BI):** It is the degree to which a person has formulated conscious plans to perform or not perform some specified future behavior (Venkatesh et al., 2003). It means the degree to what extent a consumer has formulated conscious plans to perform or not perform his/her future behavior. This determinant investigates the consumers′ opinions about continuing using s-commerce in the future. The related researches have shown that it has a direct relation with usage behavior (Ajzen and Fishbein, 1980; Ajzen, 1985; Davis et al., 1989; Taylor and Todd, 1995b, 1995c; Venkatesh and Davis, 2000). According to this, the following hypothesis was proposed:
   H6: Behavioral intention to adopt s-commerce has an effect on actual use behavior of s-commerce.

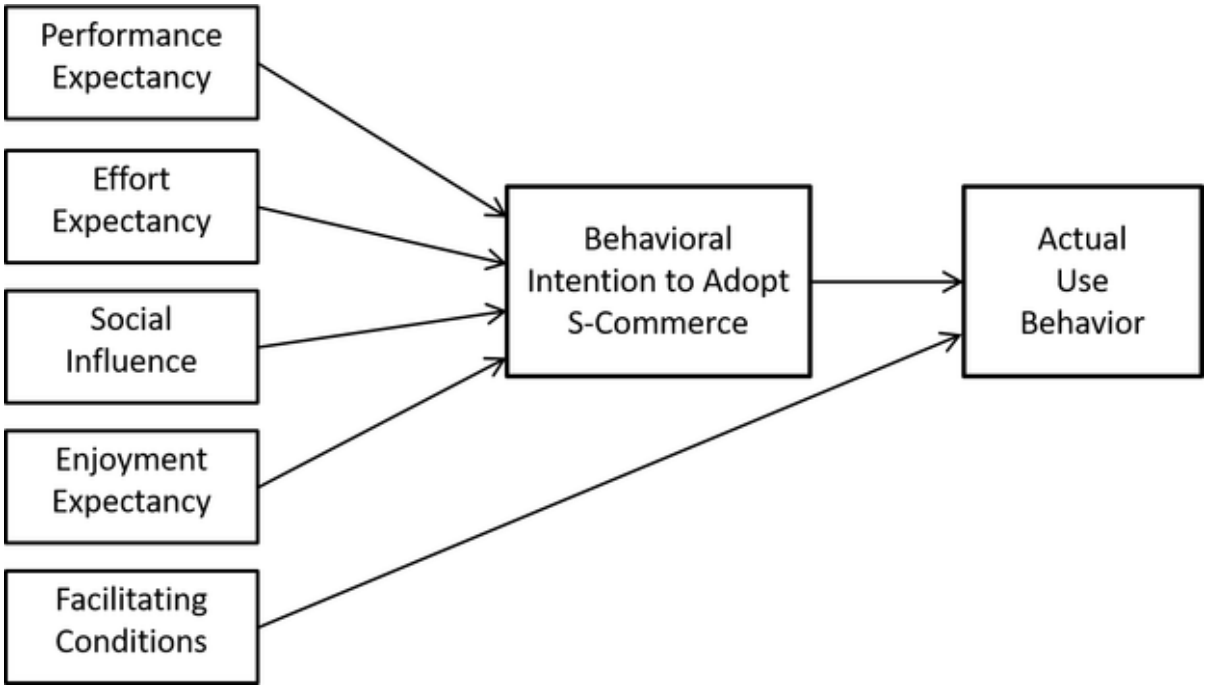
3.2. Research Instrument Design

This study utilized the survey questionnaire technique in collecting its data. As mentioned before, the research model of this study has five major determinants, or constructs, for usage intentions and actual use of s-commerce. Performance expectancy, effort expectancy, social influence, and enjoyment expectancy are influencing the behavioral intentions, while facilitating conditions has an influence on the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

actual usage behavior. Each construct is tested within the questionnaire by four statements. These statements are evaluated by five levels of agreement depending on five-point Likert-type scales (Chomeya, 2010; Pallant, 2005; Sekaran, 2003). The participant has to give his/her opinion about his/her status for each statement from the twenty-four statements presenting the s-commerce adoption acceptance test. Table 1 discusses the tested statements for each one of the five constructs, in addition to the behavioral intention factor.

Figure 1. The research model



3.3. Research Sample and Data Collection

The research population of this study is the actual users of social media within the Jordanian society who are interested in selling and buying over the internet by using their own accounts on the social networks regardless of their career area that would enhance the generalizability of the research results. The best way to define the sample size is to calculate it mathematically. This study adopted Steve Thompson′s equation for estimating the sample size (Thompson, 2012; Vincent and Thompson, 2014). After calculation, the result was at least of 273 usable responses is the target set for this study, taking into consideration, the model complexity and the guidelines of researchers for applying surveys to study the technology acceptance. Actually, a total of 282 questionnaires were collected as a primary data for this study.

Table 1. The testing statements of s-commerce acceptance test

Construct	The Related Questionnaire Statements
PE	1. Using my social network account in online shopping would enhance my effectiveness of online shopping. 2. Using my social network account in online shopping would help me more in searching for the most appropriate commodity. 3. Using my social network account would help me in discussing opinions and requirements about the commodity with the producers, suppliers, and distributors more effectively. 4. Using my social network account would ease getting reviews about the commodity from its users and discuss it with them. **References:** Alarcón-del-Amo, Lorenzo-Romero, and Gómez-Borja (2012); Ernst, Pfeiffer, and Rothlauf (2013); Venkatesh et al. (2003)
EE	1. Learning to shop through my account on social network would be easy for me. 2. Using my social network account in online shopping is clear and understandable. 3. It would be easy for me to become skillful in using my social network account in my online shopping. 4. I would find it easy to let the shopping system do what I want it to do. **References:** AbuShanab and Pearson (2007); Davis (1989); Venkatesh et al. (2003)
SI	1. Friends on my social network account positively influenced me to use the s-commerce. 2. People who influence my online shopping behavior think that I should use the s-commerce. 3. I prefer to carry the online shopping process accompanied by my family or one of my friends. 4. People who use the social commerce get the best deals than those who do not. **References:** Al Qeisi and Al-Abdallah (2014); Venkatesh et al. (2003)
EN	1. I like shopping by using my social network account more than the traditional online shopping process. 2. I find using my social network account in online shopping process is enjoyable. 3. Sharing the shopping activities between me and my friends and admiring and comments on them through social networks is an exciting process. 4. Discussing the purchasing decisions with friends through the social networking sites is much beneficial to me. **References:** Davis et al. (1992); Ernst et al. (2013); Venkatesh, Thong, and Xu (2012)
FC	1. Using my social network account in online shopping is secured whether to my personal information or in the electronic payment process. 2. By using my social network account in the online shopping, I have the whole control on the purchasing process starting from choosing the commodity as per the specifications I want and ending with completing the electronic payment successfully. 3. Specialized instructions and using-tips provided by the social online shopping site are available to me during the online shopping process through using my account on the social network. 4. From my experience, I found that the assistance and technical support teams in the social networks and social online shopping sites are ready for any assistance or queries. **References:** Alshehri (2012); Kocaleva, Stojanovic, and Zdravev (2015); Kripanont (2007); Venkatesh et al. (2003)
BI	1. I intend to continue using the social commerce in my online shopping. 2. I would use s-commerce in my online shopping to get the benefits of the use of social networking tools in the online shopping operations. 3. I predict that social commerce will enrich my online shopping experience. 4. I will recommend this experience to others. **References:** Dulcic, Pavlic, and Silic (2012); Hu, Poston, and Kettinger (2011); Lim and Ting (2012); Venkatesh et al. (2003)

4. RESULTS AND DISCUSSION

4.1. Reliability Test

Reliability analysis is an important step in any questionnaire analysis. It is the degree of accuracy of collected data and the consistency of measurements. For this study, the most popular technique was used which is the Cronbach′s coefficient alpha (α) (Field, 2009; Kline, 2011; Pallant, 2005). As mentioned by Marchewka, Liu, and Kostiwa (2007) and Hair, Black, Babin, and Anderson (2009), Cronbach′s α

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

values close to 1.0 are excellent reliability, over 0.8 are good, in the range of 0.7 are acceptable, and below 0.6 are considered to be poor. Accordingly, by using SPSS, as shown in Table 2, all Cronbach′s α values of each variable are above 0.7, and from the acceptable to the excellent level of reliability. These results indicate that the statements of each measurement item were positively correlated to one another, and they are independent measures for the measurement item.

For other evidence to the questionnaire reliability, another measure was used to assess the internal consistency, which is the inter-item correlation. Inter-item measurement measures the correlation among statements for each item (Hair et al., 2009). The correlation value from 0.10 to 0.29 is considered to be small correlation, from 0.30 to 0.49 is medium correlation, and from 0.50 to 1.0 is large correlation, all these considerations are for both positive and negative correlations (Pallant, 2005). The inter-item correlations′ values are represented in Table 2. It is clear that all the values are above 0.3. These results supported the results of Cronbach's α. And as a result, these values suggest that the questionnaire was reliable research instrument and measurement tool.

Table 2. Cronbach's alpha and inter-item correlations reliability results

Measurement Items	No. of Statements	Cronbach's α	Inter-Item Correlation
PE	4	.864	.539 – .722
EE	4	.910	.678 – .783
SI	4	.705	.311 – .459
EN	4	.842	.483 – .686
FC	4	.843	.500 – .714
BI	4	.868	.498 – .766

4.2. Validity Test

The exploratory factor analysis is a successful technique to assess the relationships among variables for exploring the construct validity of the instrument's scale. Herein, the AMOS statistical package was used to analyze the factor loading of the six scales of the proposed model. The items with values below 0.4 are considered to be low-loaded (Hair et al., 2009). Table 3 presents the loading values of all scales, and all of them are resulting values above the minimum value of factor loading.

4.3. Structural Equation Modelling (SEM)

The SEM is a general structural modelling technique which is widely used in behavioral sciences, especially in information technology researches. It describes the structural relationships among the constructs in the model. Skrondal and Rabe-hesketh (2005) mentioned that SEM contains two types of models, the measurement model and structural model. Measurement model relates the observed responses to the latent variables. Structural model then specifies the relations between the latent variables and regressions of the latent variables on the observed variables in order to describe how the constructs are related to other constructs in the model (Awang, 2012). These two models were applied herein by using AMOS:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. **Measurement Model Assessment:** Hair et al. (2009) recommended using the goodness-of-fit (GOF) measures in order to evaluate the measurement model. Several tests were applied, and the results showed that the model is from acceptable to good level of fit with values as follows: Chi-square ($\chi^2 = 419.178$), degree of freedom ($df = 237$), the relative Chi-square ($\chi^2/df = 1.769$), Comparative Fit Index (CFI = 0.953), Tucker-Lewis Index (TLI = 0.945), Incremental Fit Index (IFI = 0.953), and Root Mean Square Error of Approximation (RMSEA=0.052). All results were in good level of fit, Chi-square (χ^2) was greater than the degree for freedom (df), CFI, TFI, and IFI indices were above 0.90, finally, RMSEA was less than 0.80;
2. **Structural Model Assessment:** Within this step, the hypothesized model and its entire relations among constructs were evaluated. GOF test results were as follows: $\chi^2 = 511.280$, $df = 283$, $\chi^2/df = 1.807$, CFI=0.946, TFI=0.938, IFI=0.947, RMSEA=0.054. All results were in good level of fit. Furthermore, the standardized coefficients were presented in Table 4. It is clear that the whole the standardized path coefficient values were in the acceptable range (above 0.30). Accordingly, these results showed a good level of fit to the model.

Table 3. Factor loading of the model's measurement scales

	Factor Loading			
PE	PE1	PE2	PE3	PE4
	.672	.790	.848	.826
EE	EE1	EE2	EE3	EE4
	.836	.905	.847	.847
SI	SI1	SI2	SI3	SI4
	.600	.556	.631	.670
EN	EN1	EN2	EN3	EN4
	.741	.871	.742	.686
FC	FC1	FC2	FC3	FC4
	.670	.729	.837	.796
BI	BI1	BI2	BI3	BI4

4.4. Discussion

Actually, the technology acceptance theories that were reviewed by Venkatesh et al. (2003) showed an explanatory power in explaining the variance in the behavioral intentions at a rate ranging from 17% to 42%, while the original UTAUT showed that it can explain 69% of the variance in the behavioral intentions. It is important to mention that the squared multiple correlations (SMCs) of the research model have been estimated by AMOS in order to investigate how much the independent variables can explain the variance of the dependent variables (Nokelainen, 2009). As a result, the model has a power to explain 70% of the variance of behavioral intentions to adopt s-commerce, which is very close to the original UTAUT model. Depending on this finding, it can be concluded that the research model is viable after this modification operation.

5. CONCLUSION

SEM gave a result indicating that the performance expectancy, effort expectancy, social influence, and enjoyment expectancy are significantly influencing on the behavioral intentions to adopt s-commerce by the Jordanian consumers, while the facilitating conditions and the behavioral intentions are significantly influencing on the actual use behavior of s-commerce. These results supported wholly the hypotheses proposed within this study and showed strong statistical evidence on the validity of the research model of all constructs.

S-commerce could be an alternative to the traditional way of online shopping, because of the revolutionary features offered to the consumers. Social media communication and interaction tools make the online shopping more enjoyable, and as a result, it will increase the level of acceptance, as well as, the satisfaction of the process.

ABSTRACT

Social commerce is one of the most relevant technological innovations in recent years. It has strongly benefited many industries, including tourism. While many studies on social commerce have been conducted from the user perspective, less attention has been paid to the organisational perspective, particularly that of hotel organisations. To help understand the key drivers of hotel social commerce usage and their effects on hotel business performance, this study augments the integrated model of e-business usage and impact with hotel social media characteristics. Using stratified random sampling, data from 146 hotels in Lebanon were collected and analysed with the PLS-SEM approach. The model represents a theoretical advancement by offering an organisational perspective to the social commerce literature. It shows there is a significant impact of environmental, organisational, and innovation drivers and social media characteristics. The findings help hotels assess their existing social commerce utilization and identify aspects in need of more attention and improvement.

INTRODUCTION

Modern digital technologies such as e-commerce and social media platforms have become critical for organisations' competitiveness and survival (Benitez et al. 2018). Consumers utilise these platforms to interact with organisations and to search for a product or service information, provide reviews about products and services and encourage other existing or prospective customers to engage with the organisation. Contemporary organisations simultaneously utilise e-commerce and social media platforms to build so-called social commerce initiatives. Social commerce defined as a form of commerce mediated by social media that allow consumers to involve actively in the promoting and selling of products online (Huang and Benyoucef, 2015). Furthermore, social commerce defined as "the use of Web 2.0 applications and social media to facilitate the interactions of individuals on the Internet to support consumers' acquisition of products and services" (Doha, Elnahla and McShane, 2019, p. 307). In this study, we adopted one of many definitions of social commerce presented by Huang and Benyoucef (2015). The reason for adopting the definition provided by Huang and Benyoucef (2015) is that several social commerce models fall under this definition, including social shopping (Doha et al., 2019), group buying (Han et al., 2018). Also, this definition has been adopted in several studies of social commerce utilisation (Li, 2017; Cui et al., 2018).

Studies on the hotels' use of social commerce and its effect on business performance from an internal or organisational perspective globally and in the Lebanese hotel sector remained scarce (Hajli and Featherman, 2017). As social commerce is still in an early adoption stage, it is not well understood why hotels might benefit from utilising social commerce to enhance their business performance (Lam, Yeung and Cheng, 2019). Lebanon has been selected to be the site for the empirical side of this study for the following reasons: First, the hotel sector is one of the major businesses in the Lebanese tourism industry (WTTC, 2017) and the tourism sector contribution to economy recorded at 18.4% by 2017.The need for social commerce utilisation by hotels manifested by the unique implications of social commerce for hotels including customers, staff, and management. Social commerce enables hotels to enhance business relationships with customers, increase website traffic, and support product/services and brand development (Benitez et al. 2018; Schaupp and Bélanger 2016). customer engagement with hotels through social commerce is considered an important factor in enhancing hotel business performance (Garrido-Moreno and Lockett 2016; Harrigan et al. 2017).

Monitoring and analysing customer feedback, responding to their comments and building a digital brand reputation appear to drive online hotel performance (De Pelsmackera, Tilburg and Holthof, 2018). However, the key strategic and operational challenge in the hotel sector is to become closer to customers by realizing what attributes are most important to them, for example, reducing the uncertainty about the hotel services and products will affect customers decision making (Tran, Pham and Le, 2019). Benitez et al. (2018) stated that simply investing in social commerce does not guarantee the organisation's success in achieving its intended commercial purposes. The sustainability of social commerce is debated since the rate of buying relative to visiting is relatively small for social commerce, despite the high number of visits (Lee and Choi 2014). Hence, hotels are not convinced about the actual effect of social commerce utilisation on performance, as they cannot identify a direct return on investment from social commerce (Garrido-Moreno and Lockett 2016). Similarly, Jung et al. (2013) stated that measuring the productivity of social commerce seems to be difficult. Thus, most hotels concentrate on customer engagement rather than business performance.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Despite the growing interest in research focusing on social commerce globally, few studies have been conducted from an organisational perspective to investigate the effect of social commerce utilisation on hotel business performance (Hajli and Featherman 2017; Garrido-Moreno et al. 2018). Several authors have proposed that there is a need for additional insight into how hotels can leverage social media to effectively improve their business performance (Tajvidi and Karami 2017; Garrido-Moreno et al. 2018). This paper seeks to address the literature gap by examining social commerce utilisation in a sample of 146 Lebanese hotels. This paper is directed by the following research questions: What are the key drivers of hotels' social commerce utilisation? Does social commerce affect the business performance of hotels? The rest of the paper is arranged as follows. In the following section, the theoretical foundations and relevant literature used to develop the research model and our research hypotheses are discussed. Then, the methods, the analysis of the data and discussion of the results are discussed. The paper ends with implications for research and practice, limitations and recommendations for future research.

LITERATURE REVIEW

Most previous studies have concentrated on social commerce utilisation from the individual's perspective (Hajli 2013; Hashim et al. 2016; Sheikh et al. 2017), while less attention has been paid to social commerce from an organisational perspective, particularly with regard to organisational performance (Schaupp and Bélanger 2016; Odoom et al. 2017; Tajvidi and Karami 2017). In the hotel sector, a small number of studies have considered the effect of social commerce utilisation on hotels' performance (Garrido-Moreno and Lockett 2016; Tajvidi and Karami 2017; Zhang et al. 2017). Organisations have different perspectives and business processes than consumers; hence, organisations' utilisation may be impacted by different factors, and this is worthy of examination. This study examines the use of social commerce from an organisational perspective, specifically hotels.

Considering relevant factors, this study is based on the previous literature and concentrates on two social commerce information technology (IT) capabilities: social media and e-commerce. The study considers social media capability and e-commerce capability to be two social commerce capabilities because social media and e-commerce are the two main pillars of social commerce initiatives. Past social commerce studies, particularly in the hotel sector, have focused on the technology, organisational, and environmental (TOE) theory. Therefore, TOE has been applied in by adopting some variables as key drivers of social commerce in this study. Market pressure, IT readiness and management support are considered as relevant factors for the technology adoption and they have been added in the research framework on this study. The Resource-Based View (RBV) consider the theoretical foundation of this study. It has been used mostly in recent studies to serve as a foundation to investigate how social media relate to firm performance (Garrido-Moreno et al., 2018; Tajvidi & Karami, 2017). The reason is that RBV supports the assumption that earning a competitive advantage for the organisation depends on the application of the organisation's package of productive resources. With regard to the hotel industry, resources are the main drivers of the resource-based view (Gannon, Roper, & Doherty, 2015). There are different resources in the hotel industry containing physical, human and organisational resources. This study uses and extends the model of e-business usage and e-business impact (Zhu et al. 2006) to the domain of social commerce utilisation among hotels. This model has been used widely in e-commerce usage (Salwani et al. 2009), m-business (Picoto et al. 2014), e-government (Srivastava and Teo 2009),

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

social media (Schaupp and Bélanger 2014) and TOE factors, to explore the use of social commerce and its benefits for small businesses (Schaupp and Bélanger 2016; Tajudeen et al. 2018).

This study concentrates on social commerce utilisation by hotels, and these activities include having a social media presence, sharing posts and interacting with customers for business purposes. However, some improvements have been made to the main model, particularly measuring social commerce utilisation and business performance. In this study, social commerce measured based on three dimensions: the percentage of business conducted online, the percentage of application diversity and the percentage of social media connections with hotel partners (Parveen et al., 2016; Odoom et al., 2017). In the current study, the data were collected from the hotels. Therefore, measuring business performance mainly focuses on the indicators that align with hotels' business performance. Hotels' business performance refers to activities accomplished after the implementation of social commerce (Azizan and Said 2015). Wang et al. (2015) stated that communication performance through social commerce probably improves business performance in terms of marketing, innovation, and collaboration. Social commerce can positively affect small organisations' performance. Moreover, the intention of investing in social commerce is to improve the business performance of hotels (Anderson 2012; Cesaroni and Consoli 2015; Garrido-Moreno and Lockett 2016). According to Garrido-Moreno and Lockett (2016), hotels' business performance can be measured based on two dimensions: the effect on booking generation and the effect on sales revenue. This notion corresponds with Azizan and Said (2015) study, as the authors used the same two dimensions to measure the online business performance of hotels.

HYPOTHESIS DEVELOPMENT

The study examines nine key drivers of hotels' social commerce utilisation: market pressure, management support, IT readiness, the perception of social commerce benefits, utilisation cost, firms' cultural compatibility, visibility, editability and association. These drivers have been widely used in other studies, such as studies on e-commerce usage (Salwani et al. 2009), m-business (Picoto et al. 2014), e-government (Srivastava and Teo 2009), social media (Schaupp and Bélanger 2014) and the use of social commerce benefits among organizations (Schaupp and Bélanger 2016; Tajudeen et al. 2018). In the following paragraphs, the drivers of social commerce utilisation and previous research related to the research hypotheses are discussed.

In the current study, market pressure is identified as a driver of social commerce utilisation in which hotels are affected by customers, competitors and trading partners. Competitor pressure has been found to be an influential factor for social media adoption (Schaupp and Bélanger 2014). According to Kim (2013), low barriers to adoption may be the main factor leading to an increase in the utilisation of social commerce. In addition, Schaupp and Bélanger (2016) stated that since small organisations need to comply with stakeholders' demands, it is probable that increased pressure from customers will raise their social commerce efforts. This finding corresponds with those of several studies in the domain of e-commerce indicating that organisations are likely to utilise e-commerce due to external pressure from industry competitors, trading partners and customers (Al-Somali 2011). To test whether market pressure influences social commerce utilisation, hypothesis 1 was developed:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis 1: Market Pressure has a Positive Effect on Hotels' Social Commerce Utilisation

Management support refers to "the participation, motivation and encouragement offered by management towards the social commerce utilisation" (Schaupp and Bélanger 2016, p. 53). Management involvement is a crucial factor correlated with the efficacy of e-business adoption. Kim (2013) pointed out that top management and skilled employees are essential to the successful adoption and utilisation of social commerce in small organisations. Schaupp and Bélanger (2016) identified that most of the obstacles to social commerce utilisation faced by small organisations involve their capability to run social media technologies. Moreover, the authors stated that most small organisations' owners/managers attempt to utilise social media with little competence. To test whether management support influences social commerce utilisation, hypothesis 2 was developed:

Hypothesis 2: Management Support has a Positive Effect on Hotels' Social Commerce Utilisation

IT readiness refers to the technological infrastructure/resources and the human factors associated with technology usage. Technology infrastructure or resources refer to hardware and software resources that enable hotels to use and implement Internet and social commerce applications, which is consistent with prior studies on both e-commerce and social commerce adoption (Al-Somali 2011). In addition, human factors refer to employees with IT knowledge or skills to use and implement social commerce applications effectively (Schaupp and Bélanger 2016). IT readiness has been considered and examined in technology adoption studies as a key driver for both e-commerce and social commerce adoption (Zhu et al. 2006; Hu et al. 2016; Schaupp and Bélanger 2016). Schaupp and Bélanger (2016) stated that IT is linked to technological infrastructure/resources and that employee factors are associated with technology usage. In addition, Zhang et al. (2014) found that the availability of technological characteristics in the social commerce environment leads to maximising customer involvement. To test whether IT readiness influence social commerce utilisation, hypothesis 3 was developed:

Hypothesis 3: Information Technology Readiness has a Positive Effect on Hotels' Social Commerce Utilisation

In the current study, the perception of social commerce benefits refers to the actual benefits that hotels gain from using social commerce. These include the potential of social commerce utilisation to maximise sales, decrease costs, improve customer satisfaction, enhance communications with trading partners, achieve greater efficiency in internal processes and, most importantly, expand market share (Zhu et al. 2006; Al-Somali 2011; Schaupp and Bélanger 2016). Parveen et al. (2016) stated that the positive perceptions of the benefits of social media strongly affect the utilisation of social media in organisations. Similarly, Schaupp and Bélanger (2016) indicated that for small organisations, social commerce provides several ways to obtain business benefits such as entering a global market and performing sales and marketing at a lower cost. The authors also stated that social commerce helps in increasing exposure and site traffic for small organisations at a lower cost compared to that of traditional marketing. To test whether the perception of social commerce benefits influence social commerce utilisation, hypothesis 4 was developed:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis 4: Perception of Social Commerce Benefits has a Positive Effect on Hotels' Social Commerce Utilisation

Utilisation cost refers to the costs of implementing the necessary technologies for e-commerce and social media processes, including initial development investments and recurring operating expenses (Kim 2013; Cesaroni and Consoli 2015). Zhu et al. (2006) found that high costs significantly inhibit e-business utilisation. With regard to social commerce, researchers have argued that the costs of adoption could play a critical role in hindering or fostering organisations' decision to adopt social commerce in their online business processes. Kim (2013) stated that social commerce features enable organisations to implement this type of platform with a lower fixed cost at the initial stage, and Cesaroni and Consoli (2015) highlighted that within organisations, the adoption and use of social commerce requires a low-cost investment. On the other hand, studies have identified several obstacles to social commerce utilisation, including lack of knowledge, cost and technology incompatibility (Siamagka et al. 2015). To test whether utilisation cost influences social commerce utilisation, hypothesis 5 was developed:

Hypothesis 5: Cost of Utilisation has a Negative Effect on Hotels' Social Commerce Utilisation

Firms' cultural compatibility refers to "the degree to which social commerce applications are compatible with organisations' business processes, distribution channel and value system" (Zhu et al. 2006, p. 603). Several studies have indicated that cultural compatibility is a crucial factor in explaining technology utilisation by organisations and is one of the major determinants of the innovation spread process (Al-Somali 2011). Ndekwa and Katunzi (2016) study found that compatibility is a significant driver of the adoption of social commerce among hotels in the tourism sector. This finding corresponds to the findings of the study by Parveen (2012), who identified compatibility as an important variable that influences social commerce utilisation among organisations. To test whether the firm cultural compatibility influences social commerce utilisation, hypothesis 6 was developed:

Hypothesis 6: Firms' Cultural Compatibility has a Positive Impact on Hotels' Social Commerce Utilisation

This study seeks to add social media characteristics to the e-business use and value model (Zhu et al. 2006). The characteristics of social media (visibility, editability, association) were proposed by Treem and Leonardi (2012) to help in understanding how organisations are effectively utilising social media to improve their business performance. Visibility is defined as "the ability of social media websites that make users' behaviours, knowledge, preferences, and communication network connections that were once invisible (or very hard to see) visible to others" (Treem and Leonardi 2012, p. 150). Social media websites help an organisation's content become visible and reviewable to the audience. Wang and Zhang (2012) stated that social commerce allows organisations to reach international customers with greater efficiency compared to the traditional method of integrating user-generated content into provided products or services. Previous studies have found that the visibility provided by social media sites can enhance "the communication and business relationships with customers, boost traffic to organisation websites, create new business opportunities, and assist in product and brand development" (Huang and Benyoucef 2013, p. 247). Parveen et al. (2016) found that social media utilisation creates brand visibility for

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

organisations, and Odoom et al. (2017) discovered that the utilisation of social media has positive and significant effects on the performance benefits gained by organisations. In the hotel industry, Neirotti et al. (2016) found that hotels' online visibility has a positive impact on their revenue growth. To test whether visibility influence social commerce utilisation, hypothesis 7 was developed:

Hypothesis 7: Visibility Through Social Media has a Positive Effect on Hotels' Social Commerce Utilisation

Editability refers to "the ability to modify or revise content they have already communicated, it enables for more purposeful communication that may aid with message fidelity and comprehension" (Treem & Leonardi 2012, p. 159). Social commerce consists of the utilisation of "Internet-based media that enable users to engage in the selling, comparing, rating, buying, and sharing reviews of products and services" (Zhou et al. 2013, p. 61). By providing users the time to create and design content, editability enables more useful communication that may assist with comprehension of the message. By allowing customers to comment via social media platforms, hotels can discern what customers want and are more likely to meet customers' needs. Parveen et al. (2016) reported that developing business relationships with current and potential customers via social media platforms has a positive influence on the overall utilisation of social media by organisations. For instance, social media is utilised to receive reviews from customers on current products/services or new/future products/services. Similarly, interaction with customers through social media has a positive effect on the business performance of organisations and increases the number of customers (Odoom et al. 2017). To test whether editability influences social commerce utilisation, hypothesis 8 was developed:

Hypothesis 8: Editability Through Social Media has a Positive Effect on Hotels' Social Commerce Utilisation

Association is defined as "established connections between individuals, between individuals and content, or between an actor and a presentation" (Treem and Leonardi 2012, p. 162). Taneja and Toombs (2014) found that social media helps small businesses develop their business brand by engaging them in an interactive relationship with their competitors, the community and the broader environment. The ability to shape a new association between people and content through social media has a great influence on the social capital development of organisations (Treem & Leonardi 2012). Building a connection with prospective customers can increase the customer base, brand loyalty and reputation of organisations (Kietzmann et al. 2011). Garrido-Moreno and Lockett (2016) stated that the main advantages of building an association via social commerce for hotels are improving the image and customer proximity, and (Schaupp & Bélanger 2016) found that social commerce offers several advantages when it is used to develop relationships with customers. To test whether association influence social commerce utilisation, hypothesis 9 was developed:

Hypothesis 9: Association Through Social Media use Has a Positive Effect on Hotels' Social Commerce Utilisation

In this study, hotels' business performance is defined as activities accomplished after the implementation of social commerce (Azizan & Said 2015; Garrido-Moreno and Lockett 2016). The measurement of

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

hotels' business performance is established based on two dimensions: the effect on booking generation and the effect on sales revenue (Azizan & Said 2015; Garrido-Moreno and Lockett 2016). The intention of investing in social commerce is to improve the business performance of hotels, and research has found that social commerce can positively impact small firms' performance (Cesaroni & Consoli 2015). This finding corresponds with the study by Siamagka et al. (2015), who found that within organisations, social commerce utilisation has the potential to generate capabilities that can turn into helpful resources, which can, in turn, transform results in competitive advantages and higher performance. Odoom et al. (2017) found that social commerce utilisation significantly affects organisations' accrual of performance benefits. Odoom et al. (2017) stated that performance benefits could be obtained based on the following: increases in sales transactions, increases in the number of customers and improved brand visibility. The current study seeks to determine the extent to which social commerce utilisation impacts the business performance of hotels, specifically, booking generation and sales revenue. To answer this question, hypothesis 10 was developed:

Hypothesis 10: Increased Social Commerce Utilisation Positively Affects Hotels' Business Performance

RESEARCH DESIGN AND METHODOLOGY

This study aimed to examine the effect of social commerce utilisation on hotels' business performance in the Lebanese tourism industry. A portion of this study used a descriptive approach, as it involved obtaining demographic data, and part of it used an exploratory approach to investigate the effect of relationships between variables. The study also adopted a quantitative approach. Therefore, the data gathered via the administration of an instrument relied on predetermined questions. Lebanon has been selected to be the site for the empirical side of this study. According to Internet World Stats (2017), there were 4.6 million Internet users who constituted 76.1% of Lebanon's population. Regarding the use of social media channels, Facebook and WhatsApp are the most popular social media in Lebanon. Facebook was the topmost used with 3.3 million active users (Arab Social Media Report, 2017). Researching a developing country like Lebanon presents a valuable extension to the innovation adoption studies that have been mainly concentrated in developed countries

Instrument Development

Before distributing the questionnaires to the respondents, it was essential to check whether the items had sufficient reliability and validity. Cronbach's alpha test was used to estimate the reliability of the constructs with an acceptable reliability coefficient of 0.7 and above. To ensure construct validity, we established the measurement items based on a comprehensive review of the extant literature and expert feedback. Therefore, the study used scales and items to measure the constructs, such as scales adapted from previous e-commerce, social media and social commerce studies (Zhu et al. 2006; Treem and Leon-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ardi 2012; Parveen et al. 2016; Schaupp and Bélanger 2016; Odoom et al. 2017). In the current study, 11 constructs were measured using a set of items, and every construct contained least 4 to 5 items that were assessed using 5-point Likert scales ranging from 1 (strongly disagree) to 5 (strongly agree). All constructs and measurement items are provided in the Appendix 1. In addition, some minor modifications were made to the original items according to the comments, discussions, and feedback obtained from the pre-test and the pilot test to ensure the items were appropriate for the context of this study. This check enables the researchers to enhance the understanding of the questionnaire, develop content validity, check for instructions clarity and adequacy as well as to ensure that the questions have proper sequence or flow (Bryman & Bell, 2015). Therefore, in this study modifications were concentrated on clarifying the definitions of the concept of social commerce and instructions, reducing the length of the cover letter, grammar and questionnaire format in order to increase the comprehension of respondents. In addition, some of the items were altered to suits the Lebanese context.

Data Collection

In this study, 416 hotels in Lebanon were considered the total population. This number was obtained from the list of hotels registered with the Ministry of Tourism (MOT; Lebanon Knowledge Development Gateway 2012). The unit of analysis of this study is hotels. The respondents of the survey form are the hotel owner, general manager or director of sales and marketing (the unit of observation). A single informant was collected from each hotel and the informants are chosen not on a random basis but because of the hotel owner, general manager or director of sales and marketing possess special qualifications such as particular status, specialized knowledge, as they are responsible to set marketing strategies for hotels including social commerce. A pilot test was conducted to ensure the reliability of the items. The researcher distributed 35 questionnaires to hotel managers who were randomly selected from the target population. For the main data collection, a random sampling method was used. From a population of 416 hotels, 291 hotels were selected and invited for this survey. Some reasons were behind not covering the whole population when conducting the survey. First, we have discovered that some hotels were not applicable to social commerce activities. Second, the difficulty in delivering the survey to the target population, especially, most questionnaires were delivered personally (face-to-face). The method of delivery was a combination of self-administered questionnaires and an online survey in order to cover the large geographical distribution of hotel locations. Therefore, a total of 146 responses were received, for a response rate of 50.1%, and served as the basis for analysis. Table 1 summarises the demographic profile of the study respondents.

According to the literature, potential biases introduced by "common method variance may lead to erroneous conclusions about the relationships between variables by inflating or deflating findings" (Jakobsen & Jensen, 2015). Harman's Single Factor test" was used in this study to test the biases in variance proportion distributions of items (Lowry & Gaskin's, 2014; Ramayah et al., 2011). By conducting single factor test, the unrotated factor analysis outcomes show that the single factor appeared the ultimate variance explained accounted for 23.26%. Thus, it can be concluded that common method biases are not an obvious issue for this research.

DATA ANALYSIS AND RESULTS

The research model was examined using partial least squares (PLS), and SmartPLS 3.0 was utilised for the assessment of the measurement and structural model; these two-stage approaches were also adopted by Hair et al. (2013). PLS-SEM technique used as opposed to CB-SEM based on the following reasons (Hair et al., 2016). First, PLS-SEM has fewer restrictions on the sample size required. Second, if the structural model is complex, with various constructs and indicators, PLS-SEM is well-suited to handle the data than CB-SEM (Hair et al., 2016). Third, PLS-SEM is better equipped to handle reflective constructs.

Assessing the Results of the Measurement Model

Following the procedure suggested by Hair et al. (2013) to evaluate the measurement model, we examined the following: composite reliability (CR) to assess internal consistency and individual indicator reliability (outer loading) and average variance extracted (AVE) to assess convergent validity. The Fornell-Larcker criterion and cross-loadings were used to assess discriminant validity (Fornell and Larcker 1981; Hair et al. 2013). Internal consistency was evaluated using the outer loadings and Cronbach's alpha. (Hair et al. 2013) recommended a cut-off parameter of 0.5 for factor loading analysis in exploratory research. In this study, we found that the outer loadings for all the constructs' indicators surpassed the proposed value of 0.5. The calculation of Cronbach's alpha showed that all the variables had high levels of internal consistency reliability, greater than 0.7. Convergent validity was measured based on three criteria: (i) factor loading analysis, (ii) CR analysis, and (iii) AVE analysis, with recommended cut-off parameters of 0.5, 0.7, and 0.5, respectively (Fornell and Larcker 1981; Hair et al. 2013). The Cronbach's alpha and the CR values revealed satisfactory reliability at the construct level using the standard threshold criteria of 0.7 for Cronbach's alpha and 0.7 for CR (Fornell and Larcker 1981; Hair et al. 2013). The results for CR, Cronbach's alpha and AVE are presented in Table 2. All variables had high levels, above 0.7, of internal consistency reliability and CR. Additionally, the AVE values were well above the minimum required level of 0.50. All the tests supported the convergent validity of the scales. Discriminant validity was measured based on two methods: cross-loadings and the Fornell-Larcker criterion (Hair et al. 2013). The results showed that all the indicators' outer loadings on each of the relevant variables were higher than all their cross-loadings. The results of the cross-loadings criterion, the correlations for the constructs and the AVE values indicated discriminant validity among all the variables. Based on the Fornell-Larcker criterion, the test results showed that all the AVEs were higher than the squared inter-construct correlations, which indicated satisfactory discriminant validity among all the variables. In summary, the assessments of the measurement model indicated that the variables demonstrated appropriate measurement properties.

Assessing the Results of the Structural Model

The structural model was assessed to examine the model's predictive capabilities and the relationships between the constructs (Hair et al., 2013). The significance of t-values associated with each path was tested using the bootstrap procedure in SmartPLS 3.0 software with 146 cases and 5000 re-samples. According to Hair et al. (2013), the generally used critical values for two-tailed tests are $p<0.001(2.57)$, $p<0.05$ (1.96) and $p<0.10$ (1.65). Due to the exploratory nature of this study, the hypotheses were supported based on a significance level of $p \leq 0.001$ (Hair et al. 2013). Table 3 shows the hypothesis testing

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and the significance of the path coefficients and it illustrates that 6 of the 10 hypotheses (H_2, H_3, H_4, H_8, H_9, H_{10}) were found to be statistically significant utilising a two-tailed test, while 4 hypotheses (H_1, H_5, H_6, H_7) were not supported.

The R-square (R^2) coefficient of determination was used to evaluate the structural model. Hair et al. (2013) referred to the R^2 value as a measure of the model's predictive accuracy and calculated the squared correlation between a specific endogenous construct's actual and predictive values. The R^2 test result was 0.263 for social commerce utilisation and 0.384 for hotel business performance, indicating a moderate effect of the independent variables on the dependent variables. According to Hair et al. (2013), studies that focus on marketing issues can use the following as a rough rule of thumb: R^2 values of 0.75, 0.50, and 0.20 for an endogenous latent variable can be described as substantial, moderate and weak, respectively.

INTERPRETATION AND DISCUSSION OF RESULTS

This study modified the integrated model of e-business usage and impact by augmenting hotels' social media characteristics to examine the key drivers of hotel's social commerce utilisation and their effect on hotels' business performance in Lebanon. This approach differs from that of most of the available studies in the literature, which have concentrated on social commerce utilisation from a user's perspective but not from the perspective of organisations. Using social commerce as an example of recent technological innovations, our study fills the theoretical gap by modifying this integrated model and examining it through data collected from 146 hotels. Showing significant effects of environmental, organisational, and innovation factors and social media characteristics, the model represents a theoretical advancement from the organisational perspective in the social commerce literature.

The study results also reveal several new insights regarding specific drivers of hotels' social commerce utilisation. In response to research question 1 (What are the key drivers of hotels' social commerce usage in Lebanon?), management support, IT readiness, perception of social commerce benefits, association and editability were identified as significant and positive predictors and key drivers of hotels' social commerce utilisation. These results are consistent with the outcomes of previous studies outcomes.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Wang and Zhang (2012) found that IT readiness and management support are significant factors in social commerce research, and Schaupp and Bélanger (2016) found that the overall benefits of social commerce are significantly related to the extent of social commerce deployment in small businesses. Treem and Leonardi (2012) stated that editability and association have a significant impact on the social commerce utilisation of organisations.

Three variables were found to have no significant correlation and do not drive hotels' social commerce utilisation, namely, market pressure, utilisation costs, firm's cultural compatibility and visibility. Market pressure p=0.460 was non significant for social commerce utilisation. Scholars have argued that pressure from customers, competitors and trading partners has an influence on social commerce utilisation. For instance, Schaupp and Bélanger (2016) found that customer and competitive pressure are significant determinants of the social commerce benefits gained by an organisation. The authors indicated that competitors' social commerce initiatives mainly influence the utilisation of social commerce by organisations. Similarly, Ahmad et al. (2018) found that competitive pressure had a significant impact on social media utilisation among organisations. In contrast, competitive pressure has been found to have no impact on social media utilisation by business organisations (Schaupp and Bélanger 2014). Some possible explanations for the study's (H_1) seemingly uncertain outcome include the following. Market pressure might influence preliminary adoption but not subsequent utilisation (Lin and Lin 2008). Ahmed et al. (2018) asserted that several business organisations adopt new or trendy technology simply because the vast majority of the market is doing so. This could be the case for social commerce: many hotels may be unsure of its benefits but adopt it because of its popularity. Additionally, this finding might be explained by the fact that hotels utilise social commerce as a modern communication tool to focus on customer relationships, especially repeat customers.

Utilisation cost p=0.152 was also found to be nonsignificant for social commerce utilisation. Researchers have argued that the costs of adoption can play critical roles in hindering or fostering organisations' decision to adopt social commerce in their online business processes. Kim (2013) stated that social commerce features enable organisations to implement this type of platform with a lower fixed cost at the initial stage. Tajudeen et al. (2018) found that while social media is cost-effective, there could be some additional costs, particularly when the organisation requires dedicated professional staff to monitor, update, and regularly reply to customer queries. Moreover, launching an advertising campaign on social media incurs extra costs. Therefore, this study predicted in H_5 that utilisation cost would negatively influence the social commerce utilisation of hotels due to the additional costs that hotels may have to bear to achieve advanced levels of social commerce utilisation. However, the H_5 result indicates that there is no statistical relationship between cost and utilisation of social commerce.

Firm's cultural compatibility p=0.958 was nonsignificant in the utilisation of social commerce. A similar result was reported in the study by Ahmad et al. (2018), who found no significant relationship between compatibility and social media utilisation among business organisations. This result is also inconsistent with earlier findings. For instance, Ndekwa and Katunzi (2016) found that compatibility is one of the significant drivers of social commerce adoption among hotels in the tourism sector. A possible explanation for this outcome is that social commerce is compatible with current organisational infrastructures and operations.

The study results showed that visibility p=0.387 was nonsignificant. This result was unexpected, as hotels should exploit the visibility features provided by social media sites effectively. However, this result corresponds with the study findings of Taneja and Toombs (2014), who stated that being visible in social media is not as easy as it may appear. It is difficult for hotels with limited resources in terms

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of a skilled team to remain involved in social media networking on a continuous basis and to increase their visibility. In summary, being a social media user may not be sufficient to achieve high visibility for the hotel. In-depth understanding and advanced use of the features of social media sites such as search engine optimisation may be required to attain high visibility.

To address research question 2 (Does social commerce affect the business performance of hotels?), this study examined the relationship between social commerce and its effect on hotels' business performance, specifically the effects on booking generation and sales revenue. The finding for H_{10} p=0.049 confirmed that social commerce has a significant positive influence on hotels' booking generation and sales revenue. The finding for H_{10} addresses the problem raised in this study, namely, that the hotels are not convinced about the actual effects of social commerce utilisation on their performance, as they cannot identify a direct return on investment from social commerce (Garrido-Moreno and Lockett 2016). The study shows a positive relationship between the benefits gained from social commerce and improving the performance of hotels. This result is supported by prior studies. For instance, Cesaroni and Consoli (2015) found that social commerce can positively affect small organisations' performance and that the intention of investing in social commerce is to enhance business performance for hotels. The results also correspond to those of Siamagka et al. (2015), who found that within organisations, social commerce utilisation has the potential to generate capabilities that could turn into helpful resources, which could, in turn, transform results into competitive advantages and higher performance. Similarly, Braojos et al. (2018) found that organisation that invest and develop social commerce achieve various business benefits, such as greater innovation and customer service performance.

However, researchers have argued that social commerce utilisation is an experimental process and that for reasons of accuracy, the results should not be measured immediately (Ahmad et al. 2018). One suggestion was to require hotels of all sizes to record both the benefits realised from their social commerce investments and how they measured these benefits. According to the social commerce literature, there is no measurement standard for the effect of social commerce utilisation on performance. Based on the results of our study, we encourage social commerce scholars to examine the effect of social commerce by conducting experiments to compare whether small hotels benefit more or less than large hotels using a standardised measurement. Please refer to Figure 1 which illustrates the significant and nonsignificant hypotheses of this study.

THEORETICAL CONTRIBUTIONS, IMPLICATIONS AND CONCLUDING REMARKS

This paper makes several contributions to the literature on social commerce utilisation among hotels. It provides findings from a touristic country in the Middle East, specifically Lebanon. There is a dearth of literature in this area that considers the nuances and implications of social commerce utilisation, especially at the hotel level. This study extends the model of e-business usage and e-business impact (Zhu et al. 2006) to the domain of social commerce utilisation among hotels. This study provides empirical support from a social commerce perspective for a conceptual framework with acceptable explanatory power. Unlike the past studies that identify drivers or factors affecting utilisation of a particular type of technology, the implementation of the integrated model of e-business use and e-business impact to determine the key drivers of social commerce utilisation among hotels has demonstrated the robustness and relevance of this model.

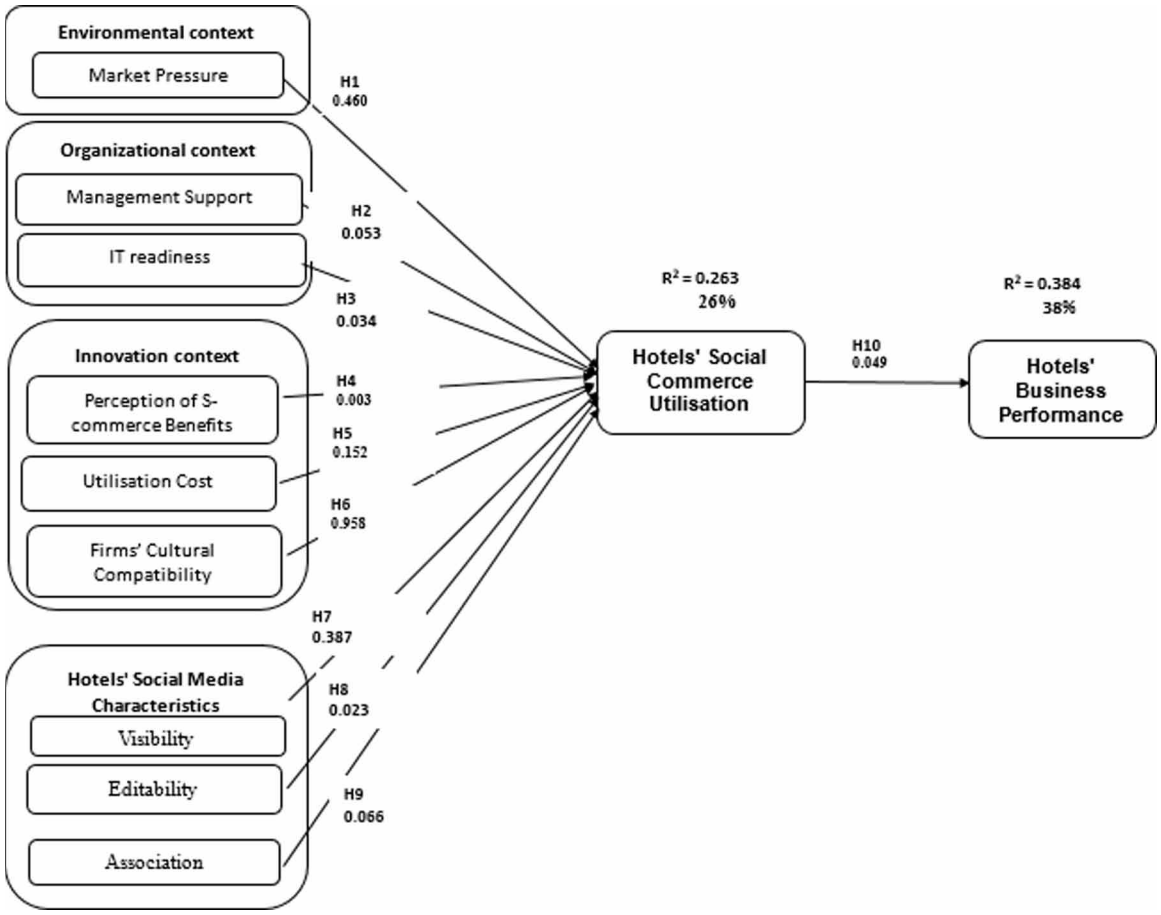
Figure 1. Illustrates the significant and nonsignificant hypotheses of this study



The effect of hotels' social media characteristics on their social commerce utilisation and business performance were not examined in extant studies (Garrido-Morren & Lockett, 2016). Social commerce has been widely applied in practice rather than in research. Thus, there was a shortage in the literature that discussed the role and the utilisation of social commerce and its effect on hotels' business performance within the organisation level, particularly among hotels (Garrido-Morren & Lockett, 2016; Schaupp & Bélanger, 2016). Therefore, in narrowing the gaps, this study contributed to the body of knowledge by incorporating and examining the hotels' social media characteristics a (visibility, editability, association) proposed by Treem and Leonardi (2012) into the model to understand how organisations are effectively utilising social media to improve their business performance. This study contributed to the body of knowledge by relating social commerce to hotels' business performance and examining its effect. The measurement of hotels' business performance was not examined in previous studies (Garrido-Morren & Lockett, 2016). Hotels' business performance was measured on two dimensions: effect on booking generation and on sales revenue (Azizan & Said (2015), this was also supported by Garrido-Morren and Lockett (2016) study. Finally, this study provides some improvements to the model by correlating the dimensions of social media to social media utilisation and business performance by identifying three

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

dimensions of social commerce: volume (percent of business conducted online), diversity (application diversity) and breadth (social media connections with its hotel partners).

The study offers several practical implications. The results can improve understanding among owners and managers of hotels, enabling them to exploit or capitalise on the possible benefits of social commerce. The study findings demonstrate the importance of management roles and IT readiness for hotels in Lebanon. In fact, without a manager's commitment and support, social commerce cannot be utilised effectively. Support from hotel management is considered imperative for improving the extent of social commerce utilisation. This study demonstrates the vital role of hotels' social media characteristics regarding visibility, editability and association in the business performance of hotels. A social media presence requires careful consideration of how to utilise social media effectively; this must be done intentionally. Hotel managers need to be clear about their social media objectives and assign expert teams/staff to update posts regularly, create marketing e-posters and respond to customer comments promptly. According to the survey responses, the use of social media varies depending on hotel classification. For instance, four- and five-star hotels assign specialised social media teams to promote their hotels' marketing strategy and embed it into their online social community. These teams are responsible for creating attractive posts, including photos and short videos, to spark the attention of audiences/users on social media sites. Two- and three-star hotels may have fewer resources to master social platforms. Taneja and Toombs (2014) stated that being visible in social media is not as easy as it may appear. It is difficult for hotels without adequate resources in terms of skilled staff and Internet technology to remain engaged in social media networking on a continuous basis and increase their visibility.

The utilisation of social media varies from one platform to another. Most hotels in different classifications have a presence in at least two social media platforms. Facebook and Instagram were at the top of the list of social media platforms used by the hotels surveyed in Lebanon, while Twitter and YouTube were used less frequently. This result is in line with the findings of the Arab Social Media Report (2017); which showed that Facebook is the most commonly used social media in Lebanon, with 3.3 million active users. The utilisation of social commerce corresponds closely to the most popular tools used locally, which implies that the hotels in this study utilised Facebook for external communication purposes. Therefore, it is important for organisations that aim to utilise social commerce as part of their organisational strategy to utilise applications that are popular and compatible with their respective context (geography or target market profiles).

The study findings can help the MOT in Lebanon to obtain a clear picture of the utilisation of social commerce among hotels. These findings could be used specifically to address the lack of studies discussing social commerce utilisation in the Lebanese context. In addition, the current study examined social commerce drivers from an organisational perspective. Therefore, other government bodies such as the Ministry of Economic and Trade (MOET) and the Ministry of Telecommunication in Lebanon could use the findings to develop an effective strategy to promote social commerce utilisation in other sectors.

LIMITATIONS AND FUTURE RESEARCH

The first limitation is that the current study examined social commerce drivers only at a specific point in time, and the use of a cross-sectional survey design does not enable the interpretation of causal inferences between constructs. The second limitation is the generalisability of the proposed social commerce model. The data were obtained from a single geographic area, Lebanon, which could hinder the generalisability

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the findings to other countries. It would be difficult to confirm the degree to which the results of this study would be generalizable to other countries without additional examination. Additionally, the data were collected from hotels in Lebanese governorates; thus, the generalisability of the findings to other business sectors could be limited without considering the characteristics of each sector. Therefore, it would be worthwhile for similar future studies to extend this research by including organisations from other industries and different countries.

CONCLUSION

This study addressed an important gap in the field of social commerce utilisation at the organisation level. By including respondents representing 146 hotels in Lebanon, this study identified several key drivers for hotels' social commerce utilisation and their effect on hotels' business performance. This study empirically extends the integrated model of e-business usage and impact (Zhu et al. 2006) to the social commerce domain by incorporating the hotel social media characteristics (visibility, editability, association) proposed by Treem and Leonardi (2012). It is believed that the proposed model is more suitable for examining social commerce utilisation from an organisational perspective, particularly for hotels. The study findings are beneficial because they offer needed guidance for hotels hoping to enhance their social commerce strategy, which could lead to enhanced business performance (booking generation and sales revenue). The findings could also provide useful insights into other business sectors that are compatible with social commerce and their respective domain.

APPENDIX

Table 4. Measurement items

Constructs	CODE	Items	References
Market Pressure	Mp1	Our industry is pressuring us to utilise social commerce	Zhu et al. (2006); Al-Somali (2011)
	Mp2	Our relationship with our customers would have suffered if we had not implemented social commerce practices	
	Mp3	Our distant partners' demands for better communications and data interchange are pressuring us to utilise social commerce	
	Mp4	The rivalry among hotels pressuring us to improve our online activities	
	Mp5	We feel that there is efficient and affordable support from the local IT industry to support our move on the Internet	
Management Support	Mgs1	Top managers are willing to provide the necessary resources for implementing social commerce practices.	Zhu et al. (2006); Al-Somali (2011)
	Mgs2	According to top managers in our firm, incorporating social commerce practices is a very important way to gain competitive advantage	
	Mgs3	Top managers often advise employees to keep track of the latest developments in Internet technologies and Internet-related business practices	
	Mgs4	Our top management is likely to consider the implementation of social commerce applications as strategically important	
	Mgs5	We have a policy that encourages social commerce initiatives	
Information Technology (IT) readiness	Itr1	Our hotel is highly computerised with internal and external network connections (i.e. Local Area Network (LAN) - Wide area network (WAN)	Zhu et al. (2006); Al-Somali (2011)
	Itr2	Our hotel has an individual(s) with expert 'knowledge of information technology (IT) and e-commerce and social media technology	
	Itr3	Our hotel has an individual(s) who could plan and carry out various parts of the evaluation procedure of social commerce implementation	
	Itr4	Our employees can understand social commerce business model	
	Itr5	Our employees are computer literate	
Perception of Social Commerce Benefits	Pscb1	Social commerce is useful to increase our hotel profitability	Schaupp and Bélanger, (2016)
	Pscb2	Social commerce is useful to expand our hotel market share	
	Pscb3	We believe that social commerce usage generates competitive advantage	
	Pscb4	Social commerce is useful to increase customer satisfaction	
	Pscb5	Social commerce is useful to communicate better with customers	
	Pscb6	Social commerce reduced our hotel's advertisement and promotion cost	
Firms Culture Compatibility	Fc1	Online booking is compatible with our hotel's current selling process	Zhu et al. (2006) And Odoom et al. (2017)
	Fc2	Conducting transactions over the Internet is compatible with existing distribution channels	
	Fc3	The chosen social media is compatible with our existing IT infrastructure	
	Fc4	The use of social commerce will help our hotels in achieving its objectives (increase sales, widen market reach, etc.)	
	Fc5	The use of social commerce is consistent with the hotel's beliefs and values	
Utilisation Cost	Uc1	The costs of social commerce applications and systems are high for our hotel	Al-Somali (2011)
	Uc2	The cost of access to the Internet is high	
	Uc3	The hosting charge for websites with sufficient bandwidth is high	
	Uc4	social commerce requires a substantial investment in training for employees to maintain a multi-skilled workforce	
	Uc5	The maintenance and support fees for social commerce applications are high for our hotel.

Constructs	CODE	Items	References
Visibility	V1	Information relevance: We use social media to provide relevant information about our hotel's services	Huang and Benyoucef (2013); Parveen et al. (2016)
	V2	Information update: We use social media regularly to update product information and social content	
	V3	Paid: Our management encourages us to pay for social media ads (ex: Facebook ads) in order to achieve wider visibility	
	V4	Presence: The presence in social media helped us to provide universal and quick access to the hotel's website	
	V5	Using social media improve our hotel's visibility	
Editability	E1	Improving Information Quality: Social media is used to offer accurate and complete information about the services offered	Huang and Benyoucef, (2013); Fox & McEwan, (2017)
	E2	Information sharing: Social media is used to motivate customers to share content and give their opinions	
	E3	Transparency: Social media is used to build transparency in terms of customers respond and services	
	E4	Trust: Social media increased our hotel's customer trust via direct conversation	
	E5	Overall, Social media improved our hotel's communication quality with customers	
Association	Ac1	Social media increased our hotel's engagement with the community	Huang and Benyoucef (2013); Parveen et al. (2016)
	Ac2	Social media increased our customer base	
	Ac3	Social media helped our hotel to target advertisements more accurately	
	Ac4	Social media increased our hotel's brand loyalty	
	Ac5	Overall, Social media enhanced our hotel's image and presence in the marketplace	
Social Commerce Utilisation	Scu1	Percentage of business-to-business sales conducted online (%)	Zhu et al. (2006); Chang and Pervan, (2007)
	Scu2	Percentage of consumers sales conducted online %	
	Scu3	Percentage of customer services conducted online (%)	
	Sc4	Overall, what is the perceived percentage of online activities (as a % of total business activities) implemented by your hotel	
Hotels' Business Performance	Hbp1	Social commerce activities increased hotel booking rate	Azizan and Said, (2015); Parveen et al. (2016)
	Hbp2	Social commerce activities contribute to the revenue	
	Hbp3	Social commerce customers repeat their web purchases	
	Hbp4	Social commerce activities generate new customers	
	Hbp5	Social commerce activities increase sales	
	Hbp6	Social commerce activities widening the sales area	
	Hbp7	The overall, social commerce activities have a positive effect on the hotel's booking generation	Azizan and Said, (2015); Garrido-Moreno & Lockett, (2016)
	Hbp8	The overall, social commerce activities have a positive effect on the hotel's sales revenue	Azizan and Said, (2015); Garrido-Moreno and Lockett, (2016)

ABSTRACT

Rapid development of e-commerce and mobile communication opens a new era of big data. In this article, the authors put big data and e-commerce security together. They construct electronic commerce security system from these aspects: the creation of database, the security of information storage, the mining of information based on big data environment thoroughly. The second-generation product distributed platform- Apache Hadoop which is more popular and instant has been brought in. what's more, this article expounds the structure and working process. On the base of this platform, this article analyses the certainty and security of e-commerce transactions data developed on the condition of big data. It puts forward a construction view that people should guide and monitor the behavior of e-commerce, and improve the security system of electronic commerce on the base of data.

1. INTRODUCTION

In September 2008, the "Big Data: Science in the petabytes Era" has been published in the famous magazine "Science." So. the "Big Data" has become a hotspot of academia and industry (Feng Deng-Guo et al., 2014). Since 1997, the company-- IBM put forward the concept of e-business (Electronic Business), as an emerging industry, which has been developed rapidly in recent 20 years. Today in the prosperous development of e-commerce, the emergence of big data increased the development of e-commerce to a new national strategy level (Wang, 2014).

E-commerce, as a digital platform, is developing rapidly, which carries a large amount of material and the structure and unstructured data. When a lot of data are growing at the same time, the security of data collection, storage and analysis has become an urgent problem to be solved in e-commerce. Recently, Internet users increase rapidly, and the network interactive ways increase variously, which has brought great convenience for information communication and information sharing. People do business activities through network, which has been a kind of fashion. At the same time, huge amounts of business transaction data are emerging constantly in the information space. These data, as the most basic organization form of e-commerce activities, are for saving energy. Data as biological cells has replicability, infectivity, transmissibility and diffusivity. When infected, it spreads quickly. The spread of transmission channels and fields is often beyond people's expectation (Chen, 2013) When people enjoy convenient communications, resource sharing and many other benefits which are brought by network, e-commerce information security is faced with unprecedented potential threats. Traditional means of data collection and analysis, faced with the arrival of the era of big data, has become overwhelmed. In the big data environment, e-commerce security research is particularly urgent and important.

Recently, scholars at home and abroad did a lot of researches on e-commerce security issues. Shu Xiwang (Shu, 2013) generalized the e-commerce security issues, especially the latest research results of e-commerce security issues. On this base, combined with the relevant technology of the big data and cloud computing, e-commerce security issues which are based on big data and cloud computing environment have been analyzed. Wang Shanjun(Wang Shanjun,2013)leaves the electronic commerce system such as the information flow, logistics and cash flow as the main research object. She used analytic hierarchy process, the most commonly used, in the Information security risk analysis to analyze security problems which caused by the three factors, and puts forward an effective e-commerce security evaluation model. Si Yingshuo (Si, Yang & Liu, 2011) analyzed E-commerce system security hierarchy by synthesis, aiming at security requirements. He put forward a kind of quantitative risk assessment model. Meng Xiao Ming (Meng Xiaoming,2006)based on OGSA security architecture and multistage agency chain thought, shows the e-commerce security structure based on grid environment, and evaluated and analyzed its safety performance. Du Yansui (Du, 2015) analyzed how cloud computing impacts development of electronic commerce. He puts forward security problems of e-commerce based on cloud computing, and gives corresponding countermeasures. However, scholars at home and abroad about the e-commerce security research which under the big data environment is relatively scarce.

This paper attempts to base on the data resources in e-commerce, and the big data views on the existing e-commerce security system, and strive to use big data analysis and processing method to enhance the defense capabilities of e-commerce security system, at the same to seek social reality in electronic commerce the common characteristics of crime phenomenon such as e-commerce theft, e-commerce fraud and so on. This behavior's safety certificate is to guarantee the safety of the e-commerce market. In the cloud computing of big data environment, using cloud computing technology reasonably is to support the intelligent management for the enterprise.

2. CONSTRUCTION OF ELECTRONIC COMMERCE SECURITY SYSTEM

2.1. Build Security Database

As the Internet enters into the Web2.0 era, Traditional relational database is not able to cope with the large scale and high concurrency Social Network Service model and the expansion of large-scale e-commerce site affairs, which exposed a lot of difficult unsolved problems and, at the same time, greatly restricted the development of the enterprise (Wu et al., 2012; Yu, 2012).

However, non-relational database with its own design concept and the scope of business processing developed very fast. Non-relational database—NoSQL (Yuan, 2010; Feng et al., 2013) is to solve the management of large-scale dataset, including data storage, concurrency control and the diversification of data, which emerges at the right moment to solve the unstructured problems. Now NoSQL have many different types, and each have their own technological advantage, data managers should combine their own needs to choose suitable NoSQL database. It can manifest the advantages of a relational database (Shen et al., 2013). NoSQL database mainly divided into the following types: The key value store database, column-oriented database, and documental database, and graphic database and so on. NoSQL database does not have a unified framework. The difference between two kinds of NoSQL databases exceeds the different kinds of two relational databases. No high and low of NoSQL, only by using NoSQL in a suitable situation which can give full play to the advantages of NoSQL.

Now, what are widely used in the database of NoSQL including Redis, Leveldb, and Mongodb, and HBase. HBase serves as the subproject of Hadoop is suitable for unstructured data storage (Li, 2014). An important characteristic of HBase is based on the column model. It will enhance the extensibility of database and improve the efficiency of database storage. What's more, HBase as a distributed database can be built on cheap server size and structured storage cluster.

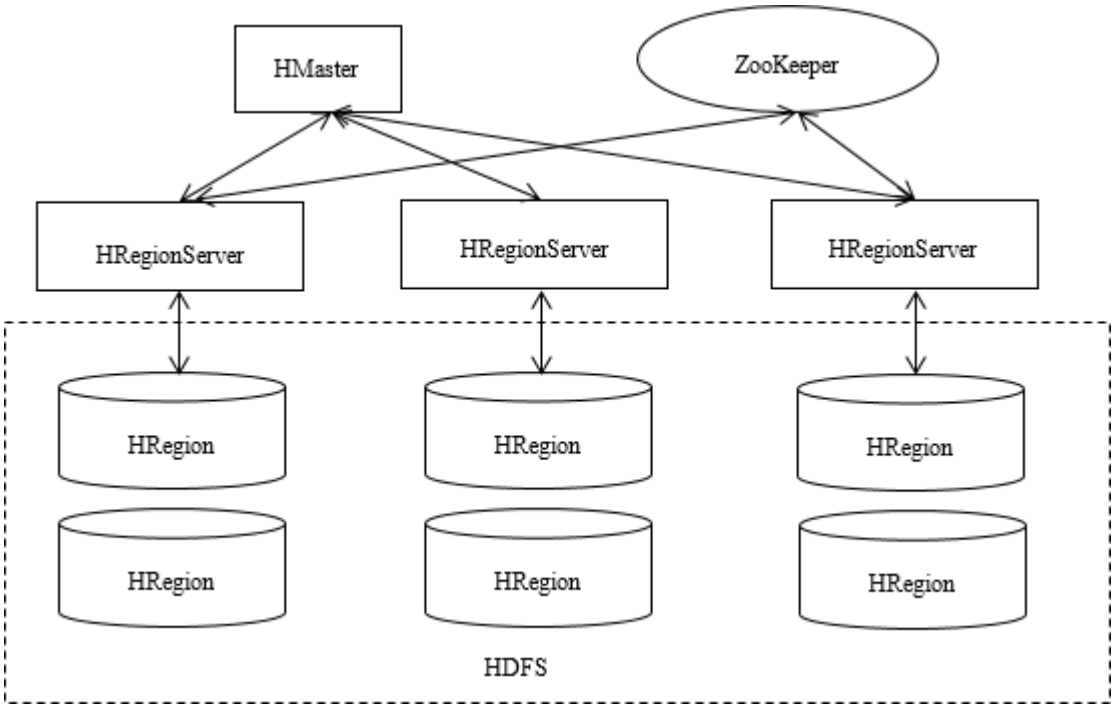
HBase is a distributed database, so it can easily deal with huge amounts of data storage, and provide the corresponding data service through management mechanism. HBase, as the database system of storage and processing large data, can directly use the local file system. It can also use the HDFS file storage system of the Hadoop.

HBase is a sparse, multi-dimensional, and sorted mapping table. The table index of HBase is line keyword, column keyword and timestamp (Yu, Youzhong & Meng, 2012). As with other NoSQL database, Storage is the string data. No difference in type. The server architecture of HBase follows simple master-slave server architecture. And its structure is shown in Figure 1. HMaster is in charge of all things. At the same time, ZooKeeper is to coordinate, but HRegionServer does not store data, and provide storage management functions. HRegion act as a storage carrier.

The data type of HBase database only includes string type, so all types are left to the user processing, which greatly reduce the test pressure of database between data type. It means HBase storage data's efficiency higher than relational database. HBase operation only includes query, insert, delete, and clear operation. Such as there has no contact between table and table, and need not to involve of multiple tables used by relational database connection, query, and so on. HBase on storage model is based on the list of storage. It is through countless files to save data. In addition, HBase is used to store data sparse, so some columns can be null.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. HBase architecture



In big data environment, it is very important whether the database access mechanism can hold huge amounts of data to access concurrently, and the database can handle huge amounts of data or not. Whether the database can storage and management the huge amounts of data or not is a very critical problem. Non-relational database solved the condition, so that we can use the data of high concurrency reading and writing requirements and the storage of mass data problems in big data, but because of the relational database on the maturity and business services is still in its infancy. Therefore, in the face of arrival of web 2.0, relational database can be used in combination (Guo, 2012). The storage structure is shown in Figure 2, the data storage controller based on the analysis of the data sources and institutions, and classified the data and stored separately to the relational database and relational database. Information index and attribute data can be stored in a relational database and record behavior, such as transaction data, which can be stored in a relational database. A data correlation controller is mainly used for the scattered data associated with key values.

E-commerce security system covers many fields of security technology. If someone wants to design an Omni bearing e-commerce security system, he has to rely on data mining and data analysis technology, and uses data to demonstrate the data, meanwhile, controls data with the data.

Data information mining research mainly divides into visual mining, memory calculation, and semantic analysis, and cloud computing technology and so on. The contents of this research mainly include the new data mining algorithm, visualization platform development, and model of machine learning research, and large data of natural language recognition, and unstructured data knowledge discovery and integration technology, etc.

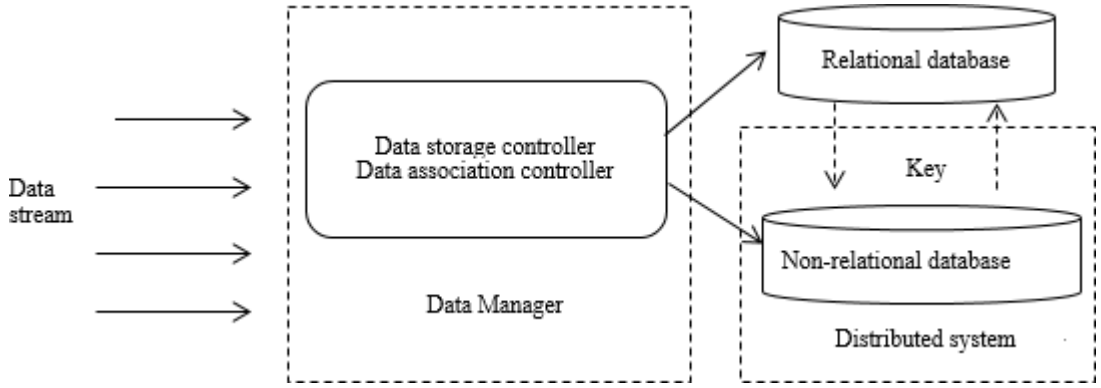
Figure 2. Joint storage database structure diagram



Big data analysis technology is under the condition of big data. It uses and improves the original data processing technique to explore network data, group, and images, graphics, etc. According relative principles of the big data to look for new technologies oriented field of network behavior and language.

The perspective of mining tasks and methods focuses on breakthrough visualization analysis, and data mining algorithm, predictive analysis, semantic engine, and data quality and data management. Data quality and management are the best practices of managements. Through the standardization process and machine process, they ensure a preset quality analysis results (Jang Bo,2010).

2.2. Safety Data Architecture Based on Hadoop

Under the wave of big data, the storage system of e-commerce need a strategy to expand the capacity, at the same time, it also need to have the ability to provide huge amounts of data services. Through the hardware resources, virtual storage technology will virtualize to manage the underlying storage device virtually. In this way, it can retain its unified logic feature and finally realize the centralized, unified, convenient management of storage system.

Cloud storage bases on cluster storage technology, it means that characteristics are hierarchical storage management, data security and on-demand deployment. Cluster distract the date load to each node, and it integrates the storage space into the huge data pool to have data management and visit uniformly. According to the data access frequency and data identification, cluster storage technology stores the data in different storage devices in order to realize the hierarchical storage management. Traditional storage file system, capacity management and disk array in the system are integrated into cluster file system through cloud storage. Traditional data security uses the way of redundant arrays of independent disks, which can only depend on the host computer to protect the date between disks. According to the set of storage, CST can realize different host computers' redundancy, it also improves guarantee of data security. In view of the traditional storage space deployment can only add server hard disk or connect network, CST may satisfy the user system demand and control the size of the storage space during conduction, which will improve the efficiency of storage and reduce the cost of investment.

With the advent of big data era, it brings new safe problems to e-commerce data storage. As people pay more attention to date, large complicated data is stored together and no one doubts the value of the data. These data storage are the target of public criticism under various attacks. As for huge amounts

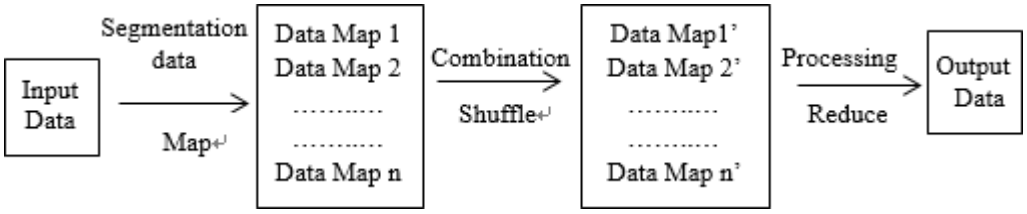
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of data, it is easy to be regarded as the carrier of advanced persistent threat by attackers. On the one hand, the traditional means of security scanning may consume too much resource. On the other hand, it is a waste of time, which already cannot satisfy the security requirements nowadays. Big data analysis platform makes it possible to process the huge amounts of data. However, if the attack on a big data technology can be used, the biggest challenge is security defense absolutely.

The establishment of information security defense system in big data era, not only inherits the advantages of the traditional security defense system, but also increases the degree of data supervision and makes the information security defense strategy. At the same time, it can improve data analysis technology under the environment of electronic commerce. Finding abnormal data points through the data analysis can even predict the occurrence of some crime.

MapReduce is a kind of data processing method. It uses map and reduction as main data processing means (Liu, 2012). Programmers may not need to know about distributed systems, but can also be used to write your own programs to calculate by distributed system. If you want to execute MapReduce, you must write a Map function first. Through a variety of mapping methods, input key value pair into a new key value pair. After processing, the programmer needs to hand it over to Reduce. Reduce collates the identical characteristic value of the data. According to a certain algorithm, integrate the data, and finally output the key value of the final result. Graphs of processing task flow chart are shown in Figure 3.

Figure 3. MapReduce task processing flow



HDFS is a distributed file system. HDFS is often deployed on the computer cluster. Because of its high fault tolerance, it can use some low performance computer as nodes. For applications with large data sets, HDFS can provide high throughput rate to access (Cheng, 2011).

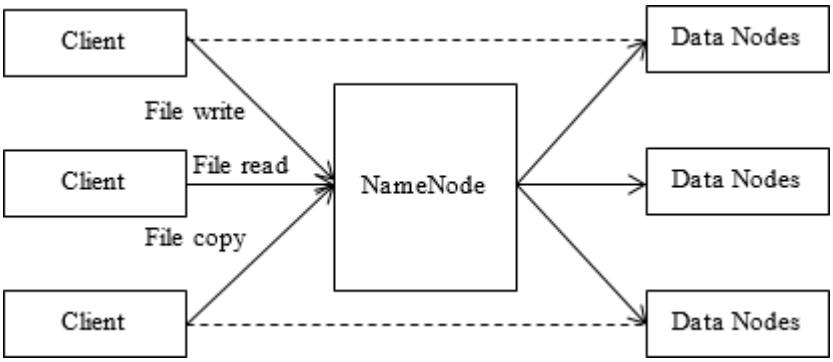
HDFS mainly uses the Name Node, Data Dode and Client to manage the file system. The NameNode as administrator in the distributed file system, undertake the management of the file system and processing mechanism of cluster configuration and related tasks. The NameNode stores information Data Node in memory, which is convenient for task allocation and control at any time. Data Node is the basic unit of file storage, as storage nodes, it through the file system to store data saved all the pieces of metadata, and periodically send all pieces of information to the NameNode. The Client is an application used to access to system files. Specific operation is shown in Figure 4.

3. DATA ANALYSIS PLATFORM CONSTRUCTION

Install Hadoop platform need Install JDK1.6 first or higher versions and the SSH protocol, using JDK1.8 in experiments.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. HDFS file operation process



First, download JDK1.8. Jar.gz to set the path began to configure the environment variables, and input sudo gedit/etc/profile commands to add the environment variables, as shown below.

Export HADOOP_HOME=/home/moon/MYData/hadoop-2.2.0
Export PATH=$PATH: $HADOOP_HOME/bin/:$HADOOP_HOME/sbin/
Export JAVA_LIBRARY_PATH=/MYData/hadoop-2.2.0/lib/native/
Export JAVA_HOME=/home/moon/MYData/jdk1.8
Export CLASSPATH=.:$JAVA_HOME/lib:$JAVAHOME/jre/lib/
Export PATH=$PATH:$JAVA_HOME/bin/:$JAVA_HOME/jre/bin/

SSH as the function of Secure Shell Protocol is to encrypt all data transmission. In the Hadoop platform, need though SSH for password-less login to start daemon process of each distribution hosts.

Because Ubuntu14.04 systems come with SSH protocol, there is no need to download, only need to input commands "ssh-keygen -t dsa" to generate a key file, as shown in Figure 5:

The key file will be appended to authorization keys, the input command is "Cat ~/.ssh/id_dsa.pub>>~/.ssh/authorized_keys", notice~ express the current folder of the users, for example /home/moon.

Through the input command: "ssh" localhost to judge whether the SSH installed successfully. If successful, the user can login this machine without password. If an error is shown like Figure 6, which expresses ubuntu14.04 version only installed ssh-agent, and did not install ssh-server, So you need to type the command: "sudo apt-get install openssh-server".then, repass "ps-elgrep ssh" Command to check, as shown in Figure 7, which shows ssh sets up successfully

Since Hadoop was launched in 2010, it has experienced several versions. In 2005, the first version of Hadoop was launched, 0.20.2 version in 2010 was known as the first-generation classic version, which contains all the previous features. Yarn, as the second-generation framework of Hadoop, solved the first generation of outstanding resource allocation, and the lack and bottleneck of task processing etc.

In this paper, the experiment used Hadoop 2.2.0 that belongs to the Hadoop second-generation products. It not only simplifies the resource consumption for Job Tracker, but also can make distributed cluster safer, and more efficient.

Figure 7. SSH login this machine interface without password

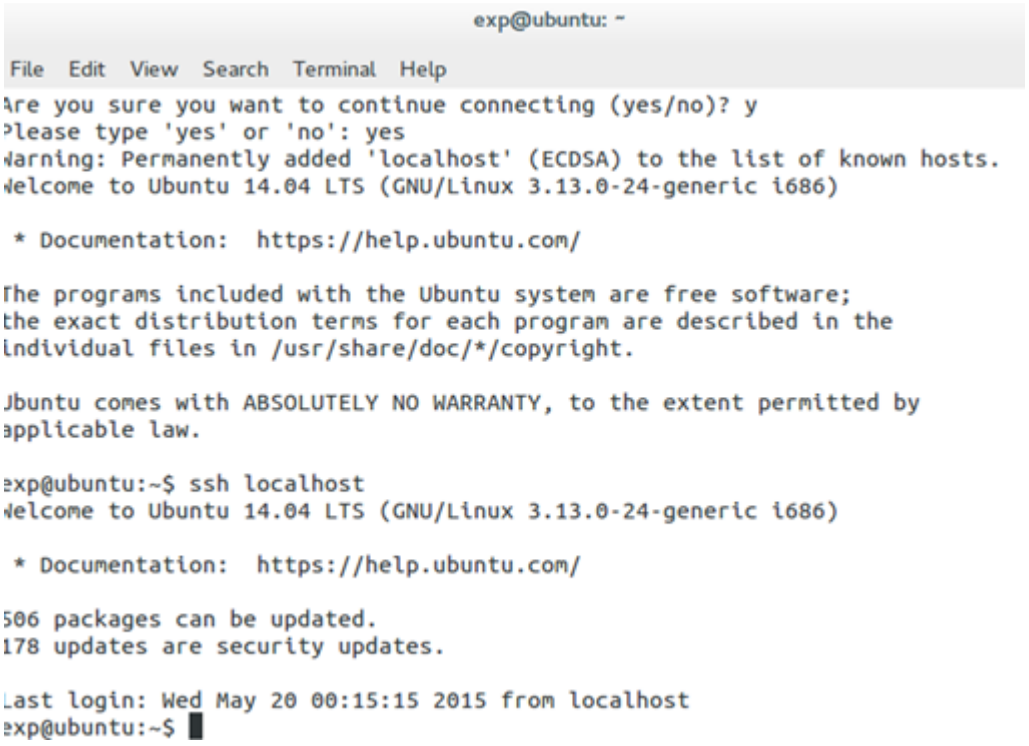

Table 1. Hadoop resource configuration

Resource name	Parameter	Meaning	Experimental value
hadoop-env.sh	parallelGC	Parallel garbage collection mechanism	XX:+UseParallelGC ${HADOOP_ NAMENODE_OPTS}
core-site.xml	fs.default.name	IP and port of NameNode	
hdfs-site.xml	Dfs.NameNode.name.dir	The log location and Storage name space of NameNode	/hadoop/dfs/namenode
hdfs-site.xml	Dfs.datanode.data.dir	location to store data blocks for DataNode	/hadoop/dfs/datanode
hdfs-site.xml	dfs.replication	Distributed file system Database replication number	2
mapred-site.xml	mapreduce.framework. name	Frame name	yarn

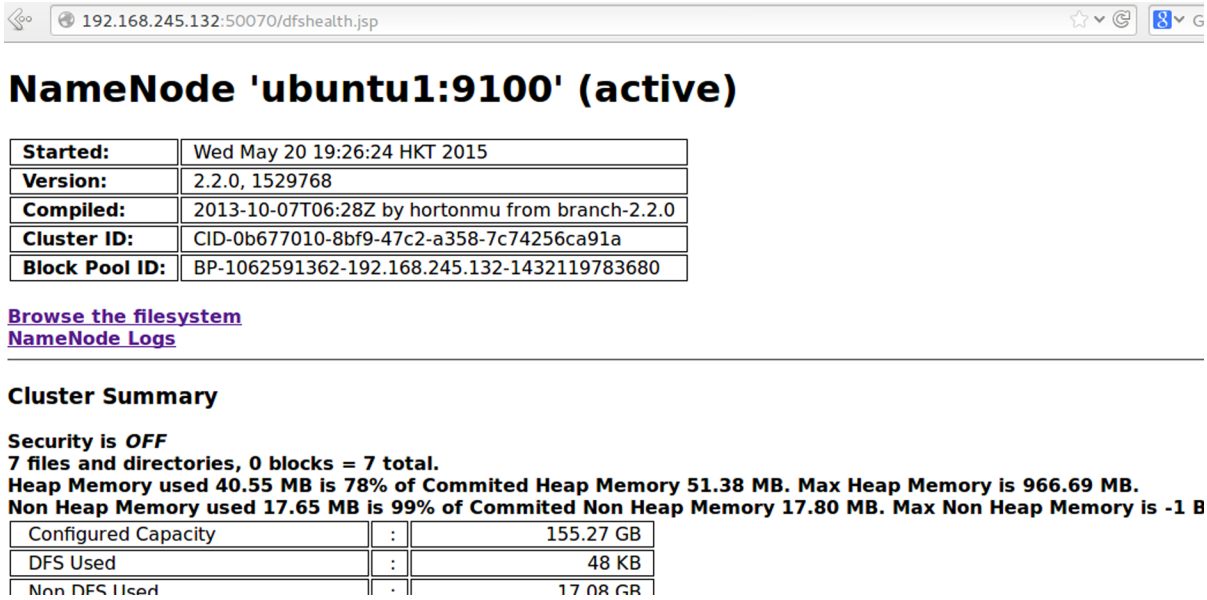
The installations of Hadoop and JDK are similar. They both can copy and cyber-install. The allocations of Hadoop have three kinds: single node mode, Pseudo-distributed mode and cluster mode. The former two ways were mainly used to test, which did not reflect the advantage of distributed systems, thus, the experiment, in this paper, adopts cluster method. The configuration of Hadoop through resource location and resources adopt XML file format.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

In regard to the configuration of Hadoop resource, as shown in Table 1, detailed resources allocation is in the literature (Guo Yizhong,2012).

Hadoop via 50070 port to manage NameNode, at the same time, it can check Name Node's Execution Log, as shown in Figure 8.

Figure 8. Hadoop system NameNode management controller



4. ELECTRONIC COMMERCE DATA ANALYSIS IN BIG DATA ENVIRONMENT

4.1. Trading Data Certainty Analysis

Log files as data sources file contains the information of transaction number, control data, input data, return data and output data and so on. When the user calls the Interface, it will produce a deal. Whether trading successful or not, it wants to through calculating the number of times of successful trading to alert the customer to notice whether the account is safe, there are several features:

1. No obvious separator, which is unfavorable for file splitting. File data formats are more which include date, Xml, characters, figures and so on.
2. Transaction number is not the only, need another judge.
3. Transaction number is non-unique, and need another judge.
4. According to the requirements, deal with the return value. Only take 1 as a symbol of a successful deal, others do not calculate.
5. Because of its complex structure, not easy to make a simple Map/Reduce, the file needs to be processed.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

a. Remove files order transaction number and return values, to calculate. This method USES a single calculation mode, suitable for a small amount of calculation and analysis of data, under the condition of big data, consume too many resources, time consuming, even unable to achieve results.
b. using the method of distributed processing, will be split into several files unit, calculated by the various units, after the results summary. This method is suitable for the large data analysis summary.

The experiment used Reduce algorithm as follows:

```
Public static class Reduce extends MapReduceBase implements
Reducer<Text, IntWritable, Text, IntWritable>
{
public void reduce (Text key, Iterator<IntWritable> values,
OutputCollector<Text, IntWritable> output, Reporter reporter)
throws IOException
{
int sum = 0;
while (values.hasNext())
{
sum += values.next().get();
}
output.collect (key, new IntWritable (sum));
}
}
```

The experimental results are shown in Figure 9:

Experimental found Map split files with behavior units. At first, an author wanted to use transaction number to divide files, but she found that the segmentation results are quite different. After a careful study, she found a Map in the treatment of the file has first for segmentation. Keyword logo matching method is used to the text in the transaction number and return value matching processing. The experiment is through configure, and deals with hadoop procedure. The results showed a better effect and rapid running. what's more, if there are any errors in program, they may soon be prompted. The query results are also very convenient.

4.2. Trading Safety Test and Analysis

Against hacker attack, modifying the data, it can also judge the time interval of data. At the same time, it is impossible to carry on the different batches of e-commerce transaction logic algorithm based on facts. The arithmetic flow chart shown in Figure 10.

Figure 9. Reduce computing hadoop program results

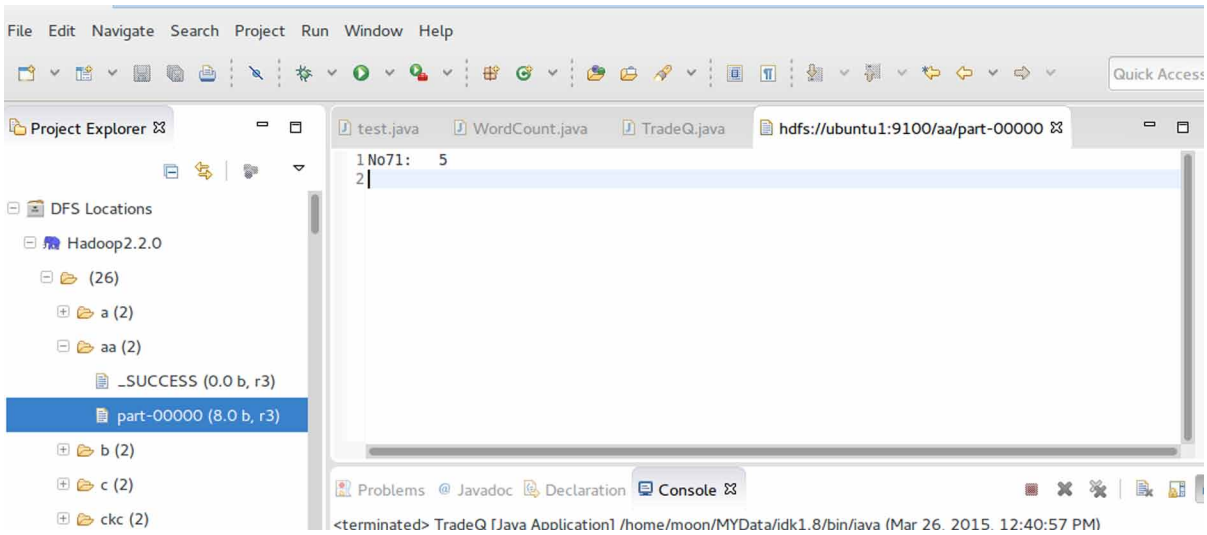

Figure 10. Data security detection algorithm flow chart

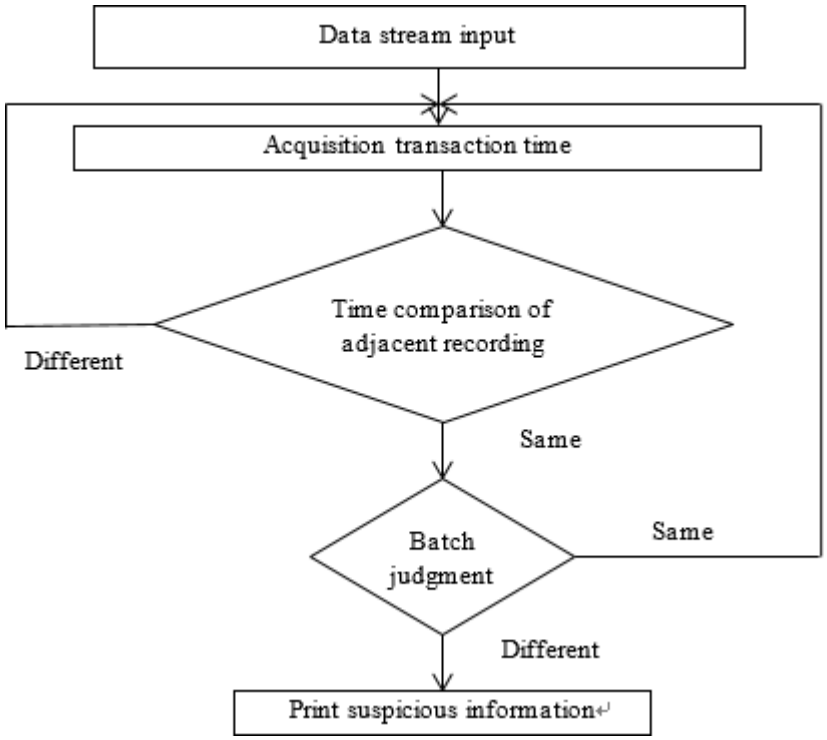

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The main design code is as follows

```
Public static void main (String [] args) throws Exception
{
JobConf conf = new JobConf (SafeCheck.class);
conf.setJobName ("trade");
conf.setOutputKeyClass (Text.class);
conf.setOutputValueClass (IntWritable.class);
conf.setMapperClass (Map.class);
conf.setCombinerClass (Reduce. Class);
conf.setReducerClass (Reduce. Class);
conf.setInputFormat (TextInputFormat.class);
conf.setOutputFormat (TextOutputFormat.class);
FileInputFormat.setInputPaths (conf, new Path (args [0]));
FileOutputFormat.setOutputPath (conf, new Path (args [1]));
JobClient.runJob (conf);
}
```

5. CONCLUSION

Electronic commerce, as the data production platform, plays a obviously important role, which has important influence on the economic development of our country. A large data processing algorithm is more complicated, and needs a lot of better capability hardware to support. Although the thought of big data has been put forward to the electronic commerce security system, after the big data platform set up, some people just did a simple calculation experiment. They didn't profoundly use more complex data analysis or processing algorithms to the experiment. Combined with complex data algorithm, large data in the field of e-commerce security research will serve as a top priority in further research.

ABSTRACT

With the rise of live streaming, many internet companies began to carry out the live streaming business, and this system was applied in various fields. Due to the emergence of e-commerce live streaming in recent years, the studies on it are not comprehensive. And for the construction of live streaming of mobile e-commerce, it is rarely considered from the perspective of users' hedonic needs. This study combined with the social presence theory to build a conceptual model explored the impact of this system on users' intention to adopt from the perspective of enjoyment feeling. The results show visual scene positively affects users' perceived enjoyment, visual scene and communication function have positive effect on social presence, social presence has positive effect on perceived enjoyment, and perceived enjoyment positively affects users' adoption intention. Finally, the authors provide practical suggestions and strategies for platform operators and sellers.

INTRODUCTION

In 2011, the first live streaming platform of online games, twitch TV (it is a free video live-streaming platform that enables viewers to watch live broadcasts of video gamers playing.) was born in the United States. Due to the changes of people's attitudes towards the computer games and mobile games and the development of international electronic competition industry, live streaming soon became popular. Due to the popularity of twitch, live streaming as a new medium has become a prevalent recreational and leisure activity in China since 2012. In 2015, a large number of companies began to invest in the field of online live streaming in China. Since that a few broadcasters have run their own online shop on Taobao or other e-commerce platforms, using the live streaming to advertise the products they sell.

In the first half of 2019, major Internet enterprises actively explored the "live +" mode, and e-commerce platforms took advantage of the "live" to drive their own business development. The simplified threshold of e-commerce platform attracts the host to stay, gathers fans, and establishes the emotional connection between the platform and consumers. From March 2018 to March 2019, among the total transactions of e-commerce platform Mogujie, the total transactions using mobile live streaming increased by 138%, and the users using mobile video live service increased by 42%. In the Chinese "618" Promotion of 2019, Taobao Mobile's live streaming led to 13 billion yuan of sales. (CNNIC, 2019)

According to the survey of China Internet Network Information Center, by June 2019, the number of mobile online shopping users reached 620 million, increased by 29.89 million over 2018.(CNNIC, 2019) By March 2020, the number of live streaming users of mobile e-commerce has reached 265 million, accounting for 37% of the users of mobile e-commerce. (CNNIC, 2020) Live streaming users of mobile e-commerce can activate users' perceptual consumption and improve the purchase rate and user experience by introducing and displaying products and interacting with users in real time.

In e-commerce, the transformation of traffic is a consideration for all e-commerce platforms. The live streaming provided by Alibaba company takes e-commerce as the core, and by embedding the live streaming into mobile Taobao and Tmall applications, it provides users with the experience of "buying while watching". With the convenience of mobile devices, users can watch live streaming anytime and anywhere. (Jiang Fan, 2018) The live streaming promotes the timely communication of information between buyers and sellers. At the same time, certain social relations will be also established in the live streaming of e-commerce for the reason of Internet celebrity so that on the role of Internet celebrity the transformation of traffic will be promoted. The short video social mobile application, Tiktok has been added mobile e-commerce system in to achieve traffic into funds. The novel coronavirus, COVID-19, emerged in China in early 2020. Under the government's strategy to respond to this crisis of the pandemic, most of the brick-and-mortar stores were suspended in China, which had an adverse impact on their sales. However, owing to no direct contact between people of the mobile e-commerce, some clothing and food brands launched relevant sales activities on the live streaming which had higher audience ratings. Although people stay at home to refrain from going outdoors as far as possible to avoid infection of COVID-19 in China, these applications help people experiencing the fun of shopping on the mobile equipment.

Compared with traditional e-commerce, main feature of mobile commerce is mobility implying portability. Users can browse e-commerce platform with mobile terminal immediately, if they want, not limited by time and place. Ubiquity, convenience, and personalization are also the features of mobile e-commerce. (Hillman & Neustaedter, 2017) The live streaming of mobile e-commerce also has these features. Using live streaming of mobile e-commerce,the buyer can also obtain three-dimensional visual

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

information and auditory information, with the needs of certain social interaction satisfied at the same time compared with traditional e-commerce.

At present, the research on user attitude and behavior intention of mobile e-commerce platform is one of the hot spots in behavior research, especially for loyalty (Dong et al., 2018), purchase intention (Dehghani et al., 2015; Erkan et al., 2016), etc. And there are also many scholars aiming at traditional e-commerce platform, social e-commerce platform based on text and image sharing (Liang and Turban, 2011; hajli, 2015; hajli, 2017; Xiang, et al. 2016; Bai, 2015). However, due to the emerging field of live streaming, the current research mainly focuses on the construction of live streaming system, and some scholars study the interaction on live streaming (He, 2013) and purchase intention on live streaming from the perspective of trust(Hyun Jung Rark, 2020).

The live streaming of mobile e-commerce is a form of high human-computer interaction. To do well in live streaming of mobile e-commerce, it not only has high requirements for the design of its computer system, but also it is need for operators and researchers to pay attention to the user's internal perception on the users' interaction with the system. However, at present, there are relatively few researches on the live streaming of mobile e-commerce. Although previous studies have explored live streaming of e-commerce from trust and perceived utilitarian value, but these studies can't fully understand the behavior mechanism of users. And for the construction of live streaming of mobile e-commerce, it is rarely considered from the perspective of users' hedonic needs and enjoyment experience. As this live streaming of mobile e-commerce is a new mode, and it has not become a main sales method of mobile e-commerce, whether all consumers accept this way or not, there is little research point out at present, so this study focuses on how to affect users' adoption intention and the role of visual and auditory characteristics of live streaming of mobile e-commerce. This paper will study from the perspective of the visual and auditory dimensions of live streaming and the user's perceived enjoyment of online shopping to explore influence mechanism, which will be a supplement to previous researches.

RELATED WORK

Research on Live Streaming

After the rise of live streaming, many researchers began to study this new human-computer interaction product. The relative research mainly includes the exploration of live streaming mode, user behavior, technical support and others.

There are two main forms of live content generation: the corresponding information generated by the host or the broadcaster and the corresponding content generated by the viewer. In the interview study of Gandolfi (2016), it was found that one of the live content generated by the broadcaster is a form of professional live content generation, and the other content is generated by the broadcaster and the viewer who share experience and attitudes on the platform. Hamilton, William & Garretson (2014) found that twitch, as a third-party virtual platform, where users communicate which promotes the formation of informal communities, and forms group identity while users share content and experience. Online live streaming was applied to citizen activities. The users who have already join in citizen activities on the live streaming have a higher sense of self-identity in the live streaming (Dougherty, 2011). Jia, et al. (2016) found that twitch.tv is a fast-consuming repository, with millions of videos uploaded, viewed

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and soon forgotten. And on the live streaming while the creator generates content emphasizing personal skills, the audience appreciated teamwork strategies.

Previous studies on live streaming mainly focused on the use motivation and perceived value of viewers and broadcasters (Max & Juho, 2017; Yu et al., 2016), while a few studies also focus on the e-commercial revenues brought by live streaming. As a kind of media for video generation and sharing, live streaming broadcasters and platforms mainly rely on the viewers' consumption of media content and advertisements to benefit.In the live streaming platforms, the platforms and the broadcasters also sell products related live streaming, including virtual medals, videos, etc., which are the main products sold by streamer and the platform to consumers. For twitch, payment subscription is a way for consumers to buy broadcasters' virtual products. Through this way, they can buy virtual products such as expression packs and badges. (Hilvert-Bruce et al., 2018) Subscriber streams is a paid browsing streams service only provided to buyers. When consumers are interested in video content through preview, they can watch it completely by purchasing subscription services(Twitch,2019). On the research of the purchasing virtual products of the live streaming platform, previous study has emphasized that social motivation will promote consumers to consume video content and choose to pay for live subscription services(Hilvert-Bruce et al., 2018). For the live streaming of entertainment, the live streaming rooms not only have the internal electronic transaction system of the live streaming platform, but also embed some web page elements that link to the external e-commerce platform. The research on twitch highlighted 35% of broadcasters will put merchandise link where the viewers can purchase relative merchandise in the live streaming rooms of Twitch. In this case, live streaming becomes a medium to introduce traffic to e-commerce platform so that live streaming indirectly participates in e-commerce transactions.(Sjöblom, Törhönen, Hamari & Macey, 2019)

For live streaming, many researches focus on perceived utilitarian value and the motivation of using live streaming, and some scholars focus on purchasing virtual products of live streaming and external e-commerce links in live streaming. It can be seen that the live streaming has been integrated into people's life, and it has also become a medium to participate in e-commerce transaction process. Therefore, it is a new hot topic to study the mode that e-commerce combines with live streaming.

Research on Mobile e-Commerce User Behavior

With the development of e-commerce, many scholars have studied e-commerce from different perspectives. Most of the researches on mobile e-commerce are based on user perceived usefulness, satisfaction, trust and other perspectives, using technology acceptance model, Expectation Confirmation model and so on. Liébana-Cabanillas et al. (2017) extended the technology acceptance model, adding other external variables to explore the user's adoption of mobile e-commerce, and perceived trust, perceived usefulness, customer customized services and user involvement have a significant impact on user adoption. Through neural network analysis, customer customized services and user involvement are the most important factors affecting user's use of mobile e-commerce.

Chong (2013a) added perceived ease of use, perceived enjoyment, trust and perceived cost to the traditional expectation verification model to build a more comprehensive research model of mobile e-commerce sustainable use intention. The results show that satisfaction, perceived usefulness, perceived ease of use, perceived enjoyment, perceived cost and trust have significant effects on consumers' sustained intention of mobile commerce. The trust of consumers is considered to be one of the most important psychological states that affect internet behavior. Previous studies have pointed out that trust has an im-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

portant impact on the acceptance of e-services, and consumer groups, types of e-services and objects of transactions are the key factors affecting consumer trust(Mou, Shin & Cohen, 2017). Hew et al. (2016) explored the user's willingness to continue to use mobile social e-commerce based on the Expectation Confirmation model, and they found social media information privacy and brand loyalty are the main influence factors. Hillman (2017) conducted an interview on the users who have used mobile e-commerce and new users who have used mobile e-commerce to investigate the impact of users' trust concerns on the use of mobile e-commerce shopping. Cheung et al. (2017) used planned behavior theory and trust relationship factors to build a model to explore the impact of advertising on user behavior intention in mobile social e-commerce applications. Hillman (2017) and Cheung et al. (2017) pointed that trust is the key factor to affect user behavior intention in mobile social e-commerce. Pantano (2016) conducted a qualitative analysis on 29 consumers in order to understand the extent that mobile technology affects consumer behavior and the driving factors of consumer experience that promote consumers to adopt mobile shopping. The results showed that retailers need to develop new mobile service capabilities to promote consumer consumption. Hyun Jung Rark (2020) studied consumers' purchase behavior of products under live streaming from the perspective of anchors and product sources. Based on the research of celebrity endorsements, their study explores the influence of various pairings on consumer behavior in the context of online shopping of online celebrities in China.

It can be seen from the above research that many scholars have studied mobile e-commerce user behavior from multiple perspectives. Due to the rise of live streaming, mobile e-commerce has added live streaming module, which is a relatively new form. At present, there is relatively little research on human-computer interaction of this kind of information system. Therefore, exploring the influence mechanism of adoption intention of mobile e-commerce live streaming will make up for the lack of research on it.

Social Presence Theory

Social presence is defined as "the extent to which an individual can feel the existence of others through media in a virtual environment" (Short et al, 1976; Gefen et al, 2003). With the continuous development of information technology, the application of social presence theory has also expanded to the fields of human-computer interaction, marketing, distance education and so on. In recent years, many scholars have extended the theory of social presence to the field of Internet user behavior. According to the theory of social presence, the more clues the media provides for people to communicate with others, the more users can feel the human warmth, emotion and sociality possessed by the media (Short et al, 1976). When users use media, when they need social emotion, they are more willing to choose the way of high sense of presence. When they just need to complete information transmission, the way of low sense of social presence can meet the needs of users. (Rice & Case,1983;Zmud, & Young,1990)In the study of user acceptance behavior toward social interaction, it is often pointed out that the main factor affecting user acceptance is the performance adaptability and social stability, while the social presence is a factor that cannot be ignored, which is the key to accepting behavior intention. Improving user's social presence in interaction is more conducive to user's accepting behavior(Shin, 2013).

With the development of Internet technology, social telepresence technology is also used in various Internet environments. For a website, its social presence is the degree to which users feel the presence of others. Lee (2014) defined the social presence as the sense of social reality felt in the online shopping environment. For social presence, many scholars think that it is the inherent attribute of the media, while some scholars think that it is the user's feeling in his mind through the use of media. Charlotte

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

et al. (1997) believed that social presence is the attribute of media is one-sided, and it is also a kind of psychological perception produced in the process of interaction between human and media, and this kind of psychological perception can be cultivated through human behavior. Sallnas (2005) indicated that social presence emphasizes the sense that one person and another exist together in the media environment.

For feeling the social presence, pictures, text information, video, virtual character image, voice and other factors will affect the degree of users to feel social presence. Gefen & Straub, 2003;Kumar, & Benbasat, 2002;Kumar, & Benbasat, 2006;Mennecke, et al,2011;Lombard & Ditton,1997;Chattaraman, Kwon & Gilbert, 2012)Compared with face-to-face business activities, e-commerce obviously lacks human warmth and social interaction. Through the integration of web interface, human warmth and social interaction will be aroused, and ultimately customers' online shopping attitude will be affected. Their research results show that high perceived social presence has a positive impact on perceived use, trust and customer pleasure of shopping websites, and through these three intermediary variables, customer attitude is improved (Khaled Hassanein & Milena Head, 2007). Although there are significant differences between offline and online store scenarios, social interaction is a common need for customers in these environments.

Social presence can reflect the user's feeling of human warmth in the use of information system. It is more suitable for the study of the user's intrinsic feelings in the use of information system, which is the reason why this study will use social presence as a factor to explore.

HYPOTHESES

In Davis's (1992) model, perceived hedonism has a positive impact on the use of information systems. For online environment, factors related to online system environment affect users' shopping behavior, and emotional cues will not directly improve the effect of effective information on shopping goals, but affect users' behavior by affecting the emotional enjoyment degree in users' shopping experience. Eroglu (2001) used online environmental cues, affect and cognition states, and user response to build a research model. Live streaming is a new form of high HCI level, so it is necessary to combine user perception from the characteristics of live streaming in mobile e-commerce for research. And perceived enjoyment and social presence can help researchers understand the intrinsic feelings of users before taking actions(Chong, Y. L., 2013b). Our research uses the above research model for reference to construct the research model with characteristics of livestreaming,perceived enjoyment and social presence. We build the research model as shown in Figure 1.

Live Streaming Feature

Because live streaming transmits information through video and audio, this study chooses visual scene and communication function as the main features of live streaming. Visual scene means the performance effect of the system presented by some visual elements such as image and video in system design (Eroglu, 2001; Vander Heijden et al., 2003). Communication function means the degree of social interaction between users and others through technology system (Animesh et al., 2011).

Compared with the image and text form, online video live streaming puts the commodity sales into a certain scene. Because of the use of video technology, it can display the commodity information more intuitively and truly, and it is easier for businesses to extract the value of products to show products to

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

users combined with the scene from multiple dimensions, from which users can find more useful information. Parboteeah et al. (2009) pointed out that when the visual effect is better, users are more likely to pay attention to the useful content. Tractinsky et al. (2000) pointed out that the visual attraction of the system increases the perceived pleasure of users. Due to the use of live streaming, the visual experience of users is more real and easier to improve the user's shopping experience. In the use of users, users browse product information by watching videos and listening to the introduction of merchants, which is closer to the form of real shopping and can meet the entertainment goals of users' shopping. Stephenson pointed out that entertainment is one of the main purposes of mass media. Eroglu et al. (2001) pointed out that the visual effects of the system, such as style and interface, are emotion related features, which produce certain atmosphere to promote the user to have a happy shopping experience. Heijden et al. (2003) pointed out that visual attraction is the main emotion related feature, which can promote users to generate pleasant and pleasant feelings. Xiang Li et al. (2016) pointed out that better visual attraction will make users generate pleasant feelings. Yee-Lin Lai et al. (2009) found that mobile animation can improve the hedonic perception of product attitude. Therefore, this study assumes that:

H1: on the live stream of mobile e-commerce visual scene will positively affect users' perceived enjoyment.
H2: on the live stream of mobile e-commerce visual scene will positively affect users' social presence.

In the live streaming of mobile e-commerce, businesses transmit information to users in the form of vision and auditory. However, information transmission is not only a one-way pattern from the seller to the user in the live streaming. Users can transmit information to other users and seller through danmaku(a type of comment which is scrolled across the particular area of screen in real time) and chat rooms. For users, mobile e-commerce live streaming has a role on satisfying users' need of social interaction. In the live streaming, users can communicate and interact with each other through the free release of danmaku to help users find the same interests, styles and shopping goals, so that they can establish relationship with like-minded people. Through this medium, users communicate and interact with each other, thus satisfying the emotional needs of users. Under the interaction of computer as the medium, the user's purchase experience can be enhanced, and then a pleasant experience of online shopping can be generated (Skadberg, 2004). Hassanein and head (2005) pointed out that when the media has interpersonal communication and sociality, it will make users feel warm. Choi (2016) pointed out that the communication between users of hedonic information system will increase the enjoyment of users. Users constantly communicate with each other through the danmaku, which virtually shortens the distance between users. When the information system is social, users will feel warm and cordial from it, resulting in a sense of social presence (Hajli, 2017). Animesh et al. (2011) pointed out that in the IT media environment, users can perceive a higher level of social presence, which will be affected by social nature. Therefore, this study assumes that:

H3: on the live stream of mobile e-commerce communication function will positively affect users' perceived enjoyment.
H4: on the live stream of mobile e-commerce communication function will positively affect users' social presence.

Social Presence

Social presence is people's perception of personal intimacy, enthusiasm, friendliness or social interaction in virtual environment. In computer-based communication, the media richness is stronger, the stronger the individual's social presence will be. In the network live streaming system, for the interaction between users and broadcasters through live broadcast in the form of danmaku or chat rooms, to a certain extent, it will give users a corresponding sense of social presence, so as to promote the communication between users and generate the pleasure value of communication and other accessories in the shopping process. Lombard and Ditton (1997) pointed out that the most prominent psychological impact of social presence is to generate pleasure. In the study of e-commerce user behavior, Hassanein (2007) thinks that the stronger the user's social presence, the more enjoyable the user's shopping experience will be; Cyr (2007) tests the impact of social presence on the user's perceived pleasure, and the results show that these two variances are positively related.

In general, the richer the media provided by online stores, the more social presence of consumers can be enhanced. Mobile e-commerce can enhance the communication and interaction between consumers and online stores or consumers through various ways such as video, push notifications in app (such as Taobao's Micro Taobao), online comments, questions to purchased consumers, live marketing, etc., which to a certain extent will make consumers have a sense of social presence. Animesh et al. (2011) pointed out that in the virtual environment, the interactivity and sociality provided by the virtual environment will affect the virtual experience of participants, and there is a correlation between the interactivity and sociality of participants and the sense of social presence. When individuals have a stronger sense of social presence, they can generate a stronger sense of pleasure and hedonic mind, and they can also have a better experience (Lombard et al., 1997). So here we assume:

H5: on the live stream of mobile e-commerce social presence will positively affect users' perceived enjoyment.

Perceived Enjoyment

Perceived enjoyment is an intrinsic emotional factor of users' adoption of information technology (Davis, 1992). Perceived enjoyment is the user's mental satisfaction after using information system. And it is the expression of users' emotional needs in the process of shopping. Hedonic attitude and utilitarian attitude are two dimensions of consumer attitude (Voss & Grohmann (2003). Consumers with hedonic attitude are pursuing emotional satisfaction while they are shopping online (Inés & Ruiz 4, 2011). Owing to the development of network technology, online shopping is no longer only a tool to meet the practical needs of users, such as product information retrieval, purchase, etc., but also a field for users to meet the enjoyment, and for users the hedonic value that can be pursued from it (Gansesh et al., 2010). In previous studies, the good mood of consumers in online and offline situations can promote their purchase behavior (Rook and Gardner, 1993; Huang, 2001). The shopping process of users online shopping affects the perception of shopping fun and the emotional response of users in the user experience, and then affects the purchase intention of users. Crawford and Melewar (2003) pointed out that when the environment can make consumers have a happy and relaxed perception, it will promote the purchase of consumers. Rodgers and Harris (2003) pointed out that when users use e-commerce shopping, insufficient perceived emotional benefits will reduce users' e-commerce activities. When us-

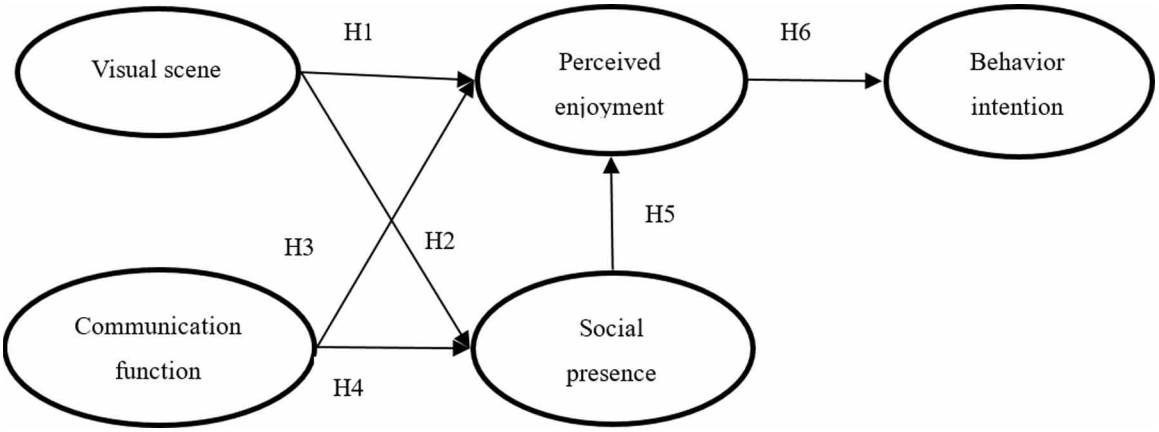
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ers enjoy online shopping experience more, users will have a longer browsing query, the more likely to adopt online shopping behavior. In the previous research on e-commerce, researchers found that users' perceived pleasure positively affected their willingness to shop (Gefen and karahanna, 2003; Parboteeah et al, 2009). Adoption intention indicates that the user has the willingness to use the information system. Therefore, this study assumes that:

H6: on the live stream of mobile e-commerce perceived enjoyment will positively affect users' adoption intention.

The above assumptions are shown in Figure 1.

Figure 1. Research theoretical model



METHODOLOGY

The questionnaire of this study mainly includes two parts: the basic demographic information and the main body measurement questionnaire. The explanation part of the questionnaire is mainly to explain the purpose of the questionnaire survey and the relevant requirements of answering questions to the respondents, so that we can obtain more authentic and reliable measurement data when the respondents exclude the concerns of personal privacy and other relevant aspect and cooperate actively. The basic personal information of the questionnaire mainly investigates the demographic information of the respondents, such as gender, age, education background, use experience. Referring to the mature scale of previous studies, combined with the characteristics of mobile e-commerce live streaming environment and the characteristics of user adoption behavior intention in this environment, this paper adopts the form of Likert 7-level scale for the measurement of all potential variables in the research theoretical model (from 1 point to 7 points, indicating very disagreeable to very agreeable) to evaluate the degree of the respondents'' approval of the question. The scales items of main body measurement questionnaire are showed in Table5.

The survey method of this study was online questionnaire, so we designed an electronic questionnaire on the professional online questionnaire platform. And then we looked for groups about e-commerce live

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

streaming of instant chat tools such as WeChat, QQ and other social software, where businesses push live streaming information, product advertisements and coupons for consumers. In order to improve the filling rate of the questionnaire, we asked group members who have experience of e-commerce webcast to help to fill in the questionnaire.

In order to ensure that the number of samples meets the specified requirements, we have set in the questionnaire whether there is any experience of using live streaming of mobile e-commerce. If not, we will not use the questionnaire. Before the participants filled in the questionnaire, we explained to them that this survey considers their feelings of the software system function, not the performance of the broadcasters and the shopping scenarios broadcasters designed. Finally, 214 valid questionnaires were collected. The demographics information is shows in Table1.

Table 1. Demographics of valid participants

items		frequency	percentage
Gender	male	73	33.11%
	female	141	65.89%
Age	<20	36	16.82%
	20-30	106	49.53%
	>30	72	33.64%
Education background	junior college education or below	41	19.16%
	bachelor	99	46.26%
	master	61	28.50%
	PhD	13	6.07%
E-commerce use experience	Less than 1 years	4	1.86%
	1-3years	43	20.09%
	3-5years	64	29.91%
	5years	103	48.13%

ANALYSIS AND RESULTS

We used spss21 and Mplus software to analyze the data we collected. Considering the limited amount of data we collected, we choose robust maximum likelihood (MLR) estimator analysis method in Mplus to analyze our data of SEM to ensure the effectiveness of the analysis.

Reliability can be used to test the consistency of the results of each observation variable index of each potential variable. In this study, Cronbach α and Composite Reliability are used as reference values of reliability.

According to the previous research on the reliability of the scale, Cronbach α coefficient below 0.650 indicates that the reliability is not good enough, α coefficient value between 0.650 and 0.700 is acceptable, Cronbach α coefficient greater than 0.700 means that the reliability of the scale of structural variables is good, and when the value greater than 0.800 indicates that the reliability of the scale

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

is very good (Fornell and Larcker, 1981). It can be seen from table 2 that the α factor values of the five variables of visual scene, communication function, perceived enjoyment, social presence, and adoption intention are all greater than 0.800, indicating that the reliability of these variables is very good. It can be seen from table 2 that the composite reliability value of each variable is between 0.8 and 0.9, which also indicates that the measurement reliability is good. Therefore, the reliability of the scale in this study is good, which meets the requirements of the follow-up study and analysis.

Table 2. Reliability analysis

Variance	Items	Cronbach α	Composite Reliability
Visual scene	V1	0.850	0.851
	V2		
	V3		
Communication function	C1	0.854	0.856
	C2		
	C3		
	C4		
Perceived enjoyment	H1	0.854	0.852
	H2		
	H3		
Social presence	P1	0.880	0.882
	P2		
	P3		
Intention	I1	0.892	0.895
	I2		
	I3		

Table 3. Validity analysis

	AVE	Visual scene	Communication function	Perceived enjoyment	Social presence	Intention
Visual scene	0.655	0.809				
Communication function	0.599	0.667	0.774			
Perceived enjoyment	0.658	0.760	0.732	0.811		
Social presence	0.713	0.730	0.761	0.772	0.844	
Intention	0.740	0.615	0.640	0.708	0.689	0.860

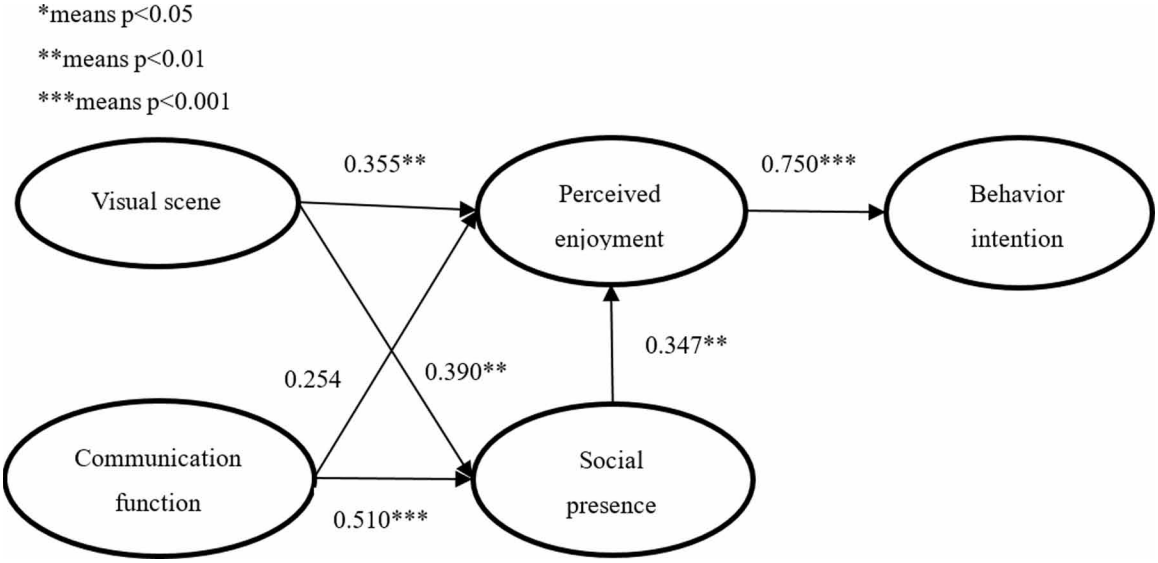
Starting from the second column, the diagonal is the square root of the AVE value of each variable, and the rest data is the correlation coefficient between the two variables

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Validity test is to test the extent to which a measurement process actually achieves the measurement purpose, that is, to test the extent to which the measurement subject of the investigation estimates the objective to be investigated, that is, to what extent it reflects the real situation. We test convergence validity and differential validity. For convergence validity, we test the ave of each variable. We follow the criteria suggested by Fornell and Larcker (1981) that AVE should be at least 0.50. From table 3, we can see that the AVE of each variable is greater than 0.5, which shows that the variable we measure has good convergence validity. In terms of the detection of differential validity, we use the correlation coefficient between variables to compare with the square root of Ave. From table 3, we can see that the square root of AVE is greater than the correlation between variables. Therefore, our measurement validity is better.

In this study, we use Mplus to set variables and build models. Because of using Mplus, we mainly use RMSEA, CFI and TLI to make quasi kernel judgment for model fitting. It can be seen from table 5.5 that the value of RMSEA is 0.033 (less than 0.05), indicating that the model fitting is acceptable. The CFI value is 0.988 (more than 0.900), and the TLI value is 0.985 (more than 0.900). For the given parameter indexes are reference to the fitting effect of the model, and the RMSEA, CFI and TLI indexes of this study are in the acceptable range. Therefore, the model has a good fit.

Figure 2. Results of SEM



It can be seen from Figure 2 that the standard path analysis and hypothesis test results of user behavior intention under mobile e-commerce live network. It can be seen from the figure that visual scene has a significant positive impact on perceived enjoyment, the significance level P is less than 0.01, and the path coefficient is 0.355; while visual scene has a significant positive impact on social presence, the significance level P is less than 0.01, and the path coefficient is 0.390. The communication function has a significant positive impact on the social presence, the significance level P is less than 0.001, and the path coefficient is 0.510; the significance level P of which the communication function has an impact on the perceived enjoyment was more than 0.05, so it has no significant impact. The positive

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

effect of social presence on perceived enjoyment was less than 0.01, and the coefficient was 0.347. The perceived enjoyment has a significant positive effect on the intention of users to adopt in the webcast, the significance level P is less than 0.001, and the path coefficient is 0.750. The results of Hypothesis test are showed in table4.

Table 4. The results of Hypothesis test

Hypothesis	content	Path coefficient	Results
H1	On the live streaming of mobile e-commerce visual scene will positively affect users' perceived enjoyment.	0.355	Supported
H2	On the live streaming of mobile e-commerce visual scene will positively affect users' social presence.	0.390	Supported
H3	On the live streaming of mobile e-commerce communication function will positively affect users' perceived enjoyment.	0.254	Not Supported
H4	On the live streaming of mobile e-commerce communication function will positively affect users' social presence.	0.510	Supported
H5	On the live streaming of mobile e-commerce social presence will positively affect users' perceived enjoyment.	0.347	Supported
H6	On the live streaming of mobile e-commerce perceived enjoyment will positively affect users' adoption intention.	0.750	Supported

DISCUSSION

Our research started from the user's experience of visual scene and communication function, and explore the impact on the impact on adoption intention with the combination of perceived enjoyment and social presence. As live streaming of mobile e-commerce is a high HCI level commerce form, it is necessary to consider the impact mechanism by combining live streaming features and users' perception. Here we do not consider the perceived utilitarian value of live streaming of mobile e-commerce which previously researches have studied, but mainly explore the impact mechanism from the perspective of hedonism.

From table4, the hypothesis H1, the hypothesis H2, the hypothesis H4, the hypothesis H5 and the hypothesis H6 were all supported, but only the hypothesis H3 was not supported. The supports of H1 and H2 prove that the effect on the visual dimension of webcast has a positive impact on the user's perceived enjoyment and social presence. Previous studies on traditional e-commerce and social e-commerce have shown that when e-commerce has a good visual effect, it will improve the user's perceived enjoyment and social presence (Eroglu et al., 2001; Xiang Li, et al., 2016; Tractinsky et al., 2000), and our research also agrees with these results. The H4 is supported, which is also similar to previous research results (Xiang Li, et al. 2016). Hypothesis H6 shows that the perceived enjoyment generated by live streaming of mobile e-commerce will promote the user's option intention for the mobile e-commerce live broadcast system. This is also similar to the previous research on traditional e-commerce, in which the effect of perceived enjoyment on users' final intention to use traditional e-commerce shopping. (Chong, 2013b; Abdennebi & Debabi,2017) It also proves our model is feasible, and shows the importance of the impact of perceived enjoyment on user adoption. However, our study found that the communication function has no direct impact on the user's perceived enjoyment, that is, hypothesis H3 isn't supported. In the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

previous researches on e-commerce and other information systems, when users use information systems and information they received is overloaded, them will feel bored and reduce their enjoyment on using the system(Hwang et al., 2020; Chen et al., 2009; Park & Lee, 2008).

Because it is on mobile device, the screen is relatively small, and the area for displaying the communication content is limited. We speculate that perhaps in the live streaming of mobile e-commerce, there are many words sent out in users' communication, and the communication content is updated quickly so that it is difficult for users to answer one by one. At this time, the information received by users is overloaded, which will affect their communication experience. However, in our research, we have not explored the reasons, and the reasons why communication function has no direct impact on the user's perceived enjoyment needs to be further explored.

CONCLUSION AND IMPLICATIONS

Our research mainly investigates the impact of live streaming on consumers' adoption intention in mobile e-commerce. Based on this research goal, we construct a research model from the perspective of the characteristics of the live streaming system to explore the mechanism of the adoption intention of users. We find that visual scene and communication function affect users' online purchase intention through social presence and enjoyment attitude. The theoretical and practical implication is as follows.

Theoretical Implication

First of all, we contribute to the literature on mobile e-commerce by investigating live streaming of mobile e-commerce, which is an emerging form of mobile e-commerce with the function of timely interaction. Previous literature on traditional e-commerce or social commerce mainly focuses on traditional platform characteristics, such as image, community and text description.(Eroglu et al., 2001; Xiang Liet al., 2016; Tractinsky et al., 2000; Heijden et al., 2003) However, mobile e-commerce with live streaming has several characteristics that differ from Previous e-commerce. Users in live streaming of mobile e-commerce can engage more deeply through real-time interactions with broadcasters. In addition, consumers can obtain product information from visual and auditory dimensions at the same time. Although recently a few researchers began to show interest in investigating user behavior in the live streaming of mobile e-commerce, but very few of them focus on enjoyment experience. Our study is among the first research to investigate adoption intention of live streaming of mobile e-commerce from the perspective of enjoyment experience. From the perspective of user's mental perception, the research makes up for the lack of the current research on this system. It is found that in human-computer interaction, the user's social presence and perceived enjoyment can be improved, and then the user's adoption behavior intention can be improved.

Second, we contribute to the literature on the behavior of mobile e-commerce live streaming by considering visual scene and communication function. Previous literature on the behavior of mobile e-commerce mainly focuses on trustworthiness and source attractiveness (Hyun Jung Rark, 2020). In the research of traditional e-commerce and social e-commerce, the characteristics of e-commerce, especially web design effect and sociability, will promote users to have a sense of pleasure and enjoyment perception, when they use it, which will promote users to use it or purchase on the e-commerce (Eroglu et al., 2001; Xiang Li et al., 2016). And many researchers find that the broadcaster-product matching

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and utilitarian value promote users' trust in product and broadcasters(Hyun Jung Rark, 2020;), while they only explore the roles of these on the choosing intention to buy on the live streaming, ignoring the role of visual characteristic and social interaction of live streaming of e-commerce. Our research explores the impact on user's intention from the factors of visual scene, communication function, social presence and perceived enjoyment, making up for the previous researches lack of exploring the role of characteristics of live streaming of mobile e-commerce.

Practical Implication

Our research is helpful for mobile e-commerce operators. At present, the mobile e-commerce live streaming environment is initially formed, but for operators, there is a large space for improvement. This study analyzes its influencing factors, aiming at online shopping of users, and provides effective strategies for mobile e-commerce live streaming operation managers and the sellers. The way sellers use live streaming to show the products should help customers visualize and understand the information that sellers introduce and display products, and consumers can enjoy this activity process. The sellers (or called broadcasters) can use the high-quality equipment helps to produce high-quality video streams, enabling customers to watch live streaming video more clearly and fluently. In order to ensure that consumers can enjoy watching live streaming video, operators should improve the video system design of mobile e-commerce live streaming, such as dynamically adjusting the code rate of uploaded video stream to adapt to most mobile devices. In the research, we point out that the communication function will affect the user's social presence which then affects the user's perceived enjoyment. It is very important for sellers to participate in the communication with users in time. The seller needs to answer the consumer's questions orally in time. Because the live broadcast can convey visual and auditory information, they should also convey non-verbal information to consumers, such as actions and expressions. Operators can optimize communication functions to promote users' willingness to adopt and improve users' enjoyment. For example, operators can use algorithms to block the upload of uncivilized discourse to reduce the load of chat system and provide a good communication atmosphere. Watching live streaming usually takes more time than browsing text descriptions and pictures of products, so broadcasters need to keep customers engaged and reduce their boredom. From our research, we know that visual scene and communication function are the factors which can promote users' enjoyment so that they can include enjoyable activities and interesting communication (e.g. Product introduction with a sense of catchwords and jokes) to interact with users in the live streaming to reduce users' boredom. The problem for sellers is how to create activities to promote users' willingness to use and watch. Finally, our research proves that this is a feasible sales model from the perspective of hedonic experience in China and even other countries around the world during the case of such a large epidemic.

LIMITATIONS AND FUTURE RESEARCH

This study is a preliminary attempt to study the user behavior of mobile e-commerce live network. We used structural equation method to explore, and selected questionnaire s to collect data. As we all know, e-commerce living streaming is a high human-computer interaction system. In this interaction process, users can not only receive the verbal information of the broadcasters, but also receive the expression and action of the host. Whether this information also affect the use of system users is not discussed in this study. In the future research, we can explore and perfect the research model through grounded theory,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and analyze and explore through objective data and from many views. At the same time, because this study is from a systematic point of view, we ignore the influence of human factors in the live streaming. In mobile e-commerce live streaming, the system has an impact on the use of viewers, but this research has not explored how other human related factors affect, such as the formation of community, which is likely to expand the research direction of this type of human-computer interaction.

Table 5. Scales items

Variance	Items	content	references
Visual scene	V1	The visual scene of mobile e-commerce livestreaming looks very comfortable	Parboteeah, et al. (2009).
	V2	The visual scene display content of mobile e-commerce live streaming is rich	
	V3	I think the online live streaming visual scene of mobile e-commerce is very humanize	
Communication function	C1	I can ask and response to other users on the live streaming of mobile e-commerce	Khan M L. (2017).
	C2	I can meet interesting users on the live streaming of mobile e-commerce	
	C3	I can stay in touch with other users on the live streaming of mobile e-commerce	
	C4	I can Share and exchange relevant information with others.	
Perceived enjoyment	H1	I feel enjoyable on the live streaming of mobile e-commerce.	Voss & Grohmann (2003); Yee-Lin Lai, et al(2009); Inés López & Ruiz (2011).
	H2	I feel happy, using the live streaming of mobile e-commerce.	
	H3	Using live streaming of mobile e-commerce, I feel it is a kind of entertainment.	
Social presence	P1	The interaction of mobile e-commerce live streaming has caused a sense of intimacy.	Hajli (2017); Chang,(2016);
	P2	I can sense the existence of others on the live streaming of mobile e-commerce	
	P3	I can discover other people's ideas on the live streaming of mobile e-commerce.	
Intention	I1	I have the desire to use live streaming of mobile e-commerce to go shopping.	Parboteeah et al. (2009);Lu & Su (2009)
	I2	I'm happy to use it.	
	I3	Trough watching live streaming of mobile e-commerce, I may purchase relevant products.

Chapter 57
A Study on Performance of E-Commerce Web Applications

Sreedhar G
Rashtriya Sanskrit Vidyapeetha (Deemed University), India

ABSTRACT

The growth of World Wide Web and technologies has made business functions to be executed fast and easier. E-commerce has provided a cost efficient and effective way of doing business. In this paper the importance of e-commerce web applications and how Internet of Things is related to e-commerce is well discussed. In the end-user perspective, the performance of e-commerce application is mainly connected to the web application design and services provided in the e-commerce website. A grading system is used to evaluate the performance of each e-commerce website.

INTRODUCTION

In the present-day scenario, the World Wide Web (WWW) is an important and popular information search tool. It provides convenient access to almost all kinds of information from education to entertainment. The World Wide Web is the key source of information and it is growing rapidly. The growth of World Wide Web and technologies has made business functions to be executed fast and easier. E-commerce has provided a cost efficient and effective way of doing business. As a large amount of transactions are performed through ecommerce sites and the huge amount of data is stored, valuable knowledge can be obtained by applying the Web Mining techniques. Using Web Mining, companies can understand customer behaviour, improve design of e-commerce site, improve customer services and relationship, and measure the success of marketing efforts and to provide personalized services. The extension in web mining research will lead to success of e-commerce sites and also it will improve the services for customers. In e-commerce websites, you can sell, advertise, and introduce different kinds of services and products in the web.

BACKGROUND

E-Commerce Web Applications

E-commerce websites have the advantage of reaching a large number of customers regardless of distance and time limitations. The advantage of e-commerce over traditional businesses is the faster speed and the lower expenses for both e-commerce website owners and customers in completing customer transactions and orders. Because of the above advantages of e-commerce over traditional businesses, a lot of industries in different fields such as retailing, banking, medical services, transportation, communication, and education are establishing their business in the web. But creating a successful online business can be a very difficult and costly task if not taking into account e-commerce website design principles, web engineering techniques, and what e-commerce is supposed to do for the online business. Unfortunately, to most companies, web is nothing more than a place where transactions take place. All the e-commerce sites have high traffic. People surf the sites very often but the income is not always very high. So, the web data mining appeared and also nowadays much attention is paid to it. It is very important to apply web data mining to e-commerce in order to gather knowledge about users and rank data accordingly. It is advance successful technology through which information is filtered easier. So, web data mining became a publicly accessible source that gives promising results. With the use of e-commerce through internet, companies find a new and better way to do business. After developing the web site thought companies get benefits, they have to implement Web mining systems to understand their customers' profiles and to identify their own strength and weakness of their E-marketing efforts on the web through continuous improvements. Internet is a gold mine, but only for those companies who realize the importance of Web mining and adopt a Web mining strategy now. Web mining technology has many important roles that should be mentioned. It can automatically find, extract information from the variety web resources. It also develops, improves and enhances the quality and the efficiency of search engines, determines web pages or files, makes classifications (Purandare, 2008). It can also generate large-scale real-time data. Web data mining discovers useful information from the Web hyperlink and page content. It has already changed the face of many business functions in a modern competitive enterprise. It is obviously easier to make right business decisions or understand the information that came from customers with the help of web data mining. It helps e-commerce to understand how to improve its services for special groups of customers and clients, and what tasks to realize. The e-commerce site can increase the exposure of its product pages and so average order size can be increased. Companies can save percentage of its budget per month owing to knowledge that was received from web mining analysis. Web data mining gathers implicit knowledge about clients and instructs e-commerce in every aspect. Then, it extracts valuable and comprehensible information from huge web resources to instruct e-commerce. It also gathers the information in an automated way and builds models used to predict customer purchasing decisions. Web mining is very precious to the company in the fields of understanding customer behaviour, improving customer services and relationship, launching target marketing campaigns, measuring the success of marketing efforts, and so on. Attractiveness of the site depends on its reasonable design of content and organizational structure. Web Mining can provide details of user behaviour, providing web site designers basis of decision making to improve the design of the site (TIAN Meirong, CHEN Xuedong, 2010). E-Commerce generally refers to a new business model, where consumer makes online shopping, online transactions between merchants and online electronic payments and a variety of business activities, trad-

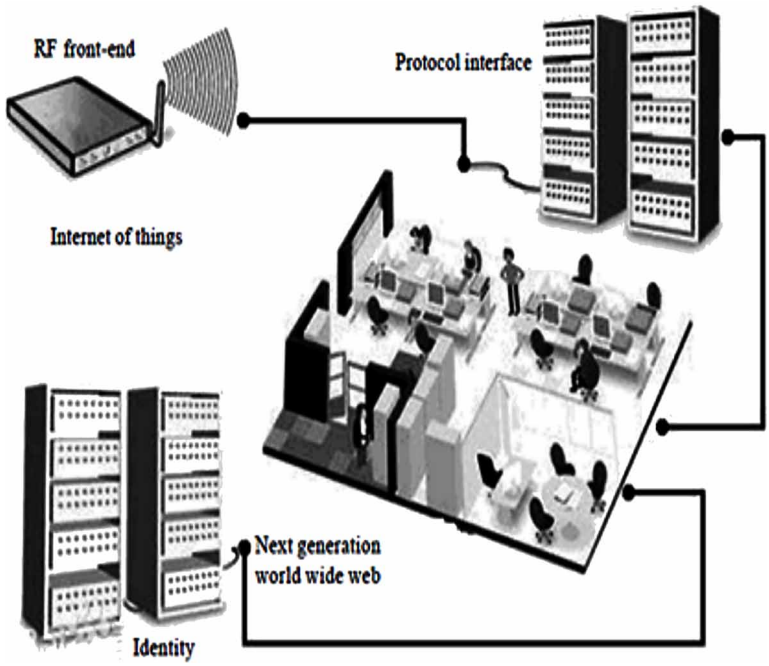
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ing activities, financial activities and related integrated services activities, buyers and sellers are not met to conduct various business activities based on browser/server application mode.

Internet of Things (IoT)

Internet of Things (IoT) is a network which is composed with Radio Frequency Identification (RFID), infrared sensors, global positioning systems, laser scanners, gas sensors and other information sensing device, according to the agreed protocol, any goods are connected with the Internet for information exchange, communication, IoT is used to make intelligent identification, positioning, tracking, monitoring and management. The schematic diagram IoT is shown in Figure 1.

Figure 1. Schematic diagram of internet of things



With the rapid development of e-commerce, its technology requirements will also increase on all aspects of future e-commerce. Firstly, the e-commerce applications are combined with IoT development and IoT technologies are applied in three important aspects of e-commerce, such as inventory, logistics and payment. An e-commerce system includes inventory, logistics, electronic payment and other important aspects, if IoT technology is used in various aspects of e-commerce, e-commerce will greatly improve the efficiency of the system. The diagram of E-Commerce with combined IoT is shown in Figure 2.

ANALYZING PERFORMANCE OF E-COMMERCE WEB APPLICATIONS

The procedure for analysing performance of e-commerce website initially starts with a web program. The program consists of two parts: extracting components of website with download time and download time performance grades. In the web program, all the components of website with corresponding downloading time are extracted using a web tool namely Web Page Analyser (Figure 1). The Download time performance grade is obtained using the web tool GTMetrix (Figure 2). The GTMetrix web tool analyses the website download time and evaluates the download time performance in A, B, C, D, E and F grades as described in Table 1.

The size of a web page is measured considering all its images, sounds, videos and textual components. For each page, the size in bytes can be obtained. The size of pages is an important issue in order to appreciate the site efficiency. The download time (T) is related with the size of a page (τ) and the speed in the established connection line (c) and this relation is shown in equation (1).

$$T_{Download} = f(\tau, c) \tag{1}$$

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Website analysis

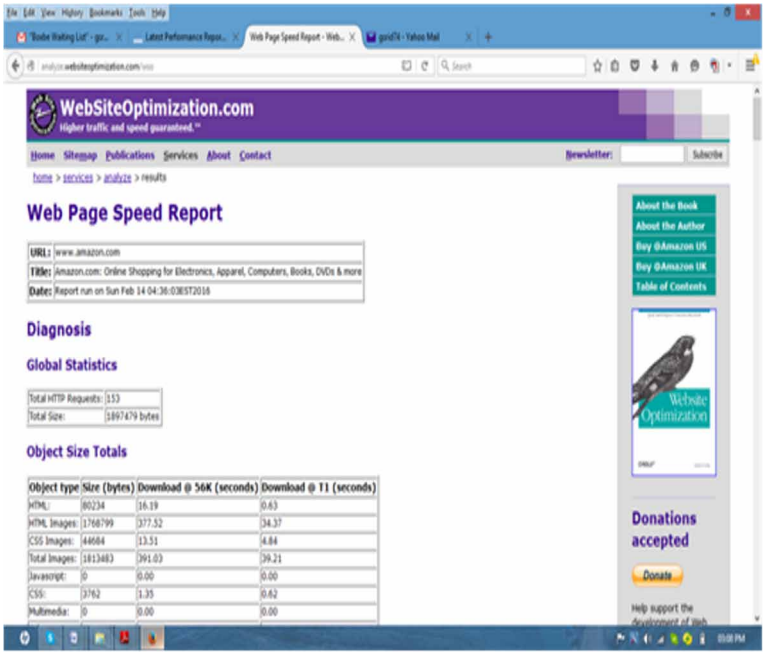

Table 1. Description of web application performance grades

Web Application Performance Grade	Description
A	Very Good
B	Good
C	Better than Average
D	Average
E	Poor
F	Very Poor

This download time is directly proportional to the page size and inversely proportional to the speed of a given connection line and it is shown in equation (2). A function may be created in order to classify pages as quick or slow access pages, according to a minimum threshold of time (e.g. 10 seconds) for a given speed of a connection line.

$$g\left(T_{Download}\right)=\begin{matrix} QuickAccess & T_{Download}<T_{\max} \\ SlowAccess & T_{Download}\geq T_{\max} \end{matrix} \quad (2)$$

The website size (Zheng Che et al, 2003), (E. Glover et al, 2002) is dependent on various components of the website. These components include Images Size, Documents size, Media Size, Programs or Scripts Size, CSS Size and other objects. As the components sizes increase then automatically the size of website is also increases. The relation between website size and web components is shown in equation (3).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$WEBSIZE = f(IMAGESIZE, DOCSIZE, MEDIASIZE, CSSSIZE, SCRIPTSIZE, OTHEROBJSIZE) \ldots (3)$$

where

WEBSIZE = Website Size
IMAGESIZE = Images Size
DOCSIZE = Documents Size
MEDIASIZE = Multimedia Size
SCRIPTSIZE = Scripts or Programs Size
CSSSIZE = Cascading Style Sheet Size
OTHEROBJSIZE = Other Objects Size like Active X Control Objects, Applets etc.

A regression analysis is carried out to analyse the relationships among these variables. The analysis is carried out through the estimation of a relationship using equation. The results serve the following two purposes.

- Answer the question of how much web size changes with changes in each of the web component's size
- Forecast or predict the value of web size based on the values of the web component's size

In analyzing the download time performance of the websites, the websites of 10 e-commerce websites are considered in evaluation process. The download time of each e-commerce website is analyzed (Figure 3) using web program and the corresponding download time performance grade is derived using GTMetrix web tool. The performance of e-commerce websites is shown in Figure 4 and Table 2.

Table 2. Performance of e-commerce web applications

S.No.	E-Commerce Website	Download Time (in secs)	Web Page Size (in M.B)	Performance Grade
1	http://goidirectory.nic.in/ministries_departments_view.php	18.3	1.76	F
2	http://goidirectory.nic.in/state_departments.php?ou=AP	4.3	0.5	F

Figure 4. Performance of e-commerce website

CONCLUSION

The main objective of the chapter is how to understand the performance of the system. In this paper the importance of e-commerce web applications and how Internet of Things is related to e-commerce is well discussed. In the end-user perspective, the performance of e-commerce applications is mainly connected to the web application design and services provided in the e-commerce website. In this paper a focused approach has been made to identify all possible parameters in the web design with specific reference to some of the major e-commerce websites. The performance of each e-commerce web application is measured in terms of web page speed and loading time of the website. Hence performance evaluation of web applications is very much necessary to fulfill the need of online user and web developer can enhance the features based on the performance report of e-commerce website.

KEY TERMS AND DEFINITIONS

Ecommerce Website: E-commerce websites have the advantage of reaching a large number of customers regardless of distance and time limitations.

GTMetrix: The download time of each e-commerce website is analyzed using web program and the corresponding download time performance grade is derived using GTMetrix web tool.

Internet of Things: Internet of Things (IoT) is a network which is composed with Radio Frequency Identification (RFID), infrared sensors, global positioning systems, laser scanners, gas sensors and other information sensing device, according to the agreed protocol, any goods are connected with the Internet for information exchange, communication, IoT is used to make intelligent identification, positioning, tracking, monitoring and management.

Web Mining: Web mining is very precious to the company in the fields of understanding customer behaviour, improving customer services and relationship, launching target marketing campaigns, measuring the success of marketing efforts, and so on.

Website Download Time: The website download time is related with the size of a page and the speed in the established connection line.

Website Size: The size of a web site is measured considering all its images, sounds, videos and textual components.

Chapter 58
Difficulty in Transition: Study on Hindrances in Online Shopping for Potential Shoppers

Chand Prakash Saini
SGT University Gurugram, India

ABSTRACT

The purpose of this article is to identify and study various risks that stop potential online shoppers to shop online. A total of 268 potential online shoppers were personally surveyed with a structured questionnaire. These respondents were from Gurgaon city. Exploratory factor analysis and regression analysis were used to assess the potential consumers' risk perception towards online retailing. It was found that potential online shoppers considered product risk, privacy risk, time risk, social risk, and security risk to be important while thinking of online shopping. Among all these risks security risks were found to be on potential online buyers' minds followed by product risk, social risk, privacy risk, and time risk. Online shopping behavior was the dependent variable in the study.

INTRODUCTION

Online retailing is the process of buying and selling over the internet (Zeithaml, Parasuraman & Malhotra, 2000). Online shopping is found to be an important online activity of Indian internet users. This is supported with an estimate of 43.8 percent digital buyer penetration in 2016, Retail web-based business deals in India added up to around 16 billion U.S. dollars that year and are anticipated to outperform 45 billion U.S. dollars in 2021. Mobile shopping has picked up pace in India as well. Around 49 percent of Indian shoppers expressed utilizing their mobiles for purchasing goods or services. This share is above the trend shown worldwide on an average – which stood at 38 percent as of 2016 – and the second-highest figure in the globe, only behind China. What is under our study is that the rest of the percentage of shoppers who have not expressed their interest in online shopping until now.

Previous researches have advocated that in comparison to offline retail consumers feel more risk in online retail because of the involvement of the internet. Despite the tremendous growth of the online retail sector in India many national and international players are struggling to find a model that can guarantee the sustainable growth in the ever-changing taste and preferences of Indian consumers' market as well as changing the business environment. Marriott & Williams (2018) when explored consumers perceived risk and trust for mobile shopping found that many buyers hesitate to shop online because of various perceived risks like privacy risk and security risk.

Previous researchers (Lee & Tan, 2003) found consumers perceived online shopping riskier than offline (Brick & Mortar) shopping and that higher levels of perceived risk influenced purchase intention. However, customers who have a lower level of perceived risk tend to shop online majorly. Miyazaki and Fernandez (2001) also advocated that the online shopping behavior of consumers is strongly governed by the perceived risk of online shopping. A consumer who either had a positive online shopping experience earlier or had a positive recommendation from their peer group will have a positive perception of online shopping. Li & Huang (2009) confirmed the same with their research that consumers feel worried that their personal information will not be safe on the internet and unauthorized access on the Internet is always a matter of worry for them. Furthermore, digital payment gateways have always shaken the trusts of the consumers for both internet banking as well as payment on the shopping sites, which affects the growth of e-commerce transactions (Hoffmann & Soyez, 2010). Thus, trust influences consumer attitudes toward online buying and assurance given by online retailers always help in lowering perceived risk in online shopping (Lee & Tan, 2003, Ha & Lennon, 2010).

REVIEW OF LITERATURE

Previous researches have been reviewed covering e-tailing, key issues, and challenges, reasons for adoption and non-adoption of e-tailing. The following are the risks identified which are creating hindrances for potential customers in the adoption of online retail.

Privacy Risk

Privacy refers to "the degree to which the online shopping web site/App is safe and protects the customers' information" (Chiu et al., 2009). Privacy in e-tailing is defined as what consumers feel about the safety of personal and financial information on the web (Bart et al., 2005) or how much the consumer is ready to share information over the web (Belanger et al., 2002). Perceived privacy risk is defined as the "likelihood that online businesses might use personal information inappropriately hence marching into a consumer's privacy" (Nyshadham, 2000). The introduction of big data and cloud computing has made privacy an increasingly important issue (Flavia´n and Guinalı´u, 2007). As a result of which consumers feel unsafe in sharing their data as they were afraid of how their data will be collected and used. (Flavia´n and Guinalı´u, 2007). Orubu (2016), attempted to study unique attributes/ determinants of trust and intention to buy online and came up with the conclusion that as the first time user of online shopping is full of doubts and usually hesitate to buy online from an unknown vendor, the same can be reduced if vendor specific guarantee with the product is associated as compared to the absence of guarantee from the other vendor. Customer's reviews of already existing customers on the online platform also place a very crucial role for the non-users to be users.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Security Risk

Security risk in e-tailing is the perception of the customer about how much are the payment gateway is secure and how well the internet firewall has been programmed filtered (Kolsaker and Payne, 2002). Further, some authors defined security risk as "the technical aspect of ensuring the reliability, confidentiality, authentication, and non-recognition of relationships". Previous researchers have advocated security as a key aspect of studying user attitudes toward online services (Suh and Han, 2002). Consumers perceive security risk when they pay through the credit card or debit cards that probably their account will be hacked and money loss will be there. Literature shows that perceived security risk is an important predictor of internet banking adoption as customers find it very risky to disclose their account information. Chelder et al. (2006), found perceived web security to be an important factor in customer's acceptance of online shopping. Perceived risk for security among online shoppers results in negative behavior towards online shopping (Rathee & Saini, 2017). Suki and Suki (2017) studied the perceived risk and customer trust in online buying in case of holiday makers while using internet bookings for their holidays and revealed the associations between internet perceived risk and equal influence of product e-channel risk in customers trust played equal role.

Customers will be interested in online purchases only if they feel that all the financial information and another sensitive piece of information is safe, customers may panic that unofficial party access to their online account and it will result in serious financial loss. In a study that has been conducted in Britain on internet banking (White and Nteli, 2004), consumers rank the security asses the service quality of the bank's web site based on security it provides to the customers. Yet another study on online retail and consumer behavior, security concern about password leak, use of email-ids, credit card details were found to be very significant (Huang and Oppewal, 2006). Consumers' confidential information can be used unethically (e.g., name, address, password, social security, and credit card numbers) and often result in identity theft (Milne et al., 2004). In most of the instances, the benefit of e-tailing like convenience, time, and/or financial savings afforded to consumers are offset by privacy issues.

Product Risk

Oghazi P. (2018) suggested that major hindrance customer feel about online shopping, is product risk that is they may be delivered wrong/ expiry / used products and online retailers can minimize these risks by offering easy return policy to the customers and if they will follow this strategy the purchase intention of buyer through online platform increases. Consumers' decisions whether or not to shop online are also influenced by the type of product or service they require. It is being observed that it depends on the nature of the product that an individual customer is shopping for like for some product categories they will feel very confident in the online channel while at the same time may feel hesitant for other categories. Since shopping on the internet does not have the physical interaction between buyer and seller this is one factor that influences its attractiveness. Another factor is the need to feel, touch, smell or try the product, which is not possible when shopping online. Following this, clearly standardized and familiar products such as books, videotapes, CDs, groceries, and flowers, have a higher potential to be considered when shopping on the Internet, especially since quality uncertainty in such products is virtually absent, and no physical assistance or pre-trial is needed (Garbarino et al., 2008). On the other hand, personal-care products like perfume and lotion, or products that require personal knowledge or experiences like computers and cars, are less likely to be considered while shopping online (Elliot and Fowell, 2000).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Time Risk

Time risk equals to customer's risk of wasting valuable time in searching product and waiting for an uncertain delivery (Chen and Sherrell, 2004). On-time delivery will satisfy the customer, which will decrease time risk. On-time delivery makes the customer realize that the retailer is effective. On-time delivery is a very important component of customer satisfaction. Customers' dissatisfaction will increase as the item is not delivered on time or not arrive at all (Grewal et al., 2002). The potential loss of time associated with making a bad purchasing decision by wasting time researching, shopping, or have to replace the unexpected goods. (Chen & Sherrell, 2004).

Time from a different point of view is one of the factors that relates to the attractiveness of online channels of shopping. It is observed that different consumers have a different angle of their own for including time as a factor of choice for online shopping, whether or not to shop from the internet. According to (Grewal et al., 2002), accomplishing the task of shopping at the earliest refers to the time-saving oriented consumers and they always favor their own store choices to make it quick; customers who are not very fond of shopping and approaching for time-saving retail stores refer to the economic shoppers ". In online shopping, it requires less effort and better decision making for consumers who opt to purchase at the e-store (Chen and Sherrell, 2004). Customers may spare their time in e-shopping since they don't need to experience any exertion on going to a shopping center or sparing their time in other psychological factors, for example, automobile overload and so on.

Social Risk

"Potential loss of status in one's social group as a result of adopting a product or service, looking foolish or unpopular" (Bosque & Sanchez, 2009). Social risks concern potential loss of status in one's social gathering, for example, being laughed at by others, and refusal of membership into a social gathering.

(Lee and Turban, 2001) describe perceived social risk as to the loss of self-esteem due to the reputation of the store from your social group family and friend. Feathersman (2003) defines perceived social risk as to the type of risk that relates to how the reference group will perceive the selection of retail stores and the purchase of a product. Perceived social risk is the risk that a poor store decision will result in social humiliation (Schiffman & Kanuk, 2007). Social risk reflects the disappointment in the individual by his friends in case of a poor product/service choice (Lee and Turban, 2001). Social risk can be defined as the potential loss of esteem, respect, and/or friendship offered to the consumer by other individuals and is more likely to occur with services because of the service encounter Social risk: Reflects disappointment in the individual among friends. Social risk is the risk undertaken by the different members of society in terms of positive or negative perception (Lee and Turban, 2001).

OBJECTIVES

1. To identify the factors creating hindrance in online shopping for potential online shoppers.
2. To study the impact of identified factors on potential online shoppers' behavior.

RESEARCH METHODOLOGY

Research Design

This study is based on an exploratory cum descriptive research design. Exploratory research design has been used to identify the factors that potential online shoppers relate to online retail and descriptive design has been used to make the concept clearer. The ethical considerations have been kept into the mind by referencing the others' work in case of secondary data and primary data is also being collected with the consent of the respondents.

Sample Design

Because of the limitation of time and financial resources, it was not possible to study the census. Therefore, a sample of 300 respondents has been taken from Gurgaon city. Out of 300 distributed questionnaires 290 responses were collected and 268 responses found correct for further research. The correct data response rate was 92%. For the study, Purposive sample design has been used. Purposive sample design justified on the ground that only those respondents were taken who had no prior experience of online shopping.

Data Collection

Both primary and secondary data have been taken for the study. Primary data has been collected through the questionnaire technique. The questionnaire framed under this study was divided into two parts. Part A covers the demographic information and Part B covers the 44 statements related to the risks in online shopping based on a five-point Likert scale with scale anchors from "1" – strongly disagree to "5" – strongly agree. Secondary data has been collected through books, journals, articles, newspapers and web sites.

Statistical Tools Used

Collected questionnaires were coded and entered into SPSS spreadsheet for analyzing the data. After entering the data exploratory factor analysis, stepwise regression and mean were used for analyzing the data.

Data Analysis and Interpretation

Exploratory Factor analysis technique has been used for identifying the factor acting as the risk for potential online shoppers. Factor analysis is techniques through which variables that are correlated with one other but independent of other variables are combined into factors (Malhotra and Dash, 2016). Before applying factor analysis, appropriateness of factor analysis has been checked. For this purpose, Kaiser-Meyer-Olkin measure of sample adequacy and Bartlett's test of sphericity has been performed (Table 1).

Higher the value of KMO and Bartlett greater will be the reliability of factor analysis. The value of KMO should be greater than 0.5 for applying factor analysis. In this study, the value of KMO comes 0.966 (Table 1) considered as excellent. It means our sample size was adequate and factor analysis can be used for reducing data.

The rotated component matrix is also called a Rotated Factor matrix in factor analysis. We used the varimax method of rotation. Table 2 depicts the factor loading for each variable into each factor. Factor loading less than 0.6 is not shown in the table because we neglected those loadings.

Table 2 depicts that Factor 1(Security) includes S1-S4. Factor 2 (Privacy) includes S5- S11 Variable. Factor 3 (Time Risk) included S12- S21 variables Factor 4 (Social Risk) includes the variable S22-S31 and S32- S44 comes under the fifth factor (Product Risk).

Table 3 shows the name of every factor and which variable comes under which factor with their scores. It can be seen that the average loading of each factor is more than 0.5 which is a good value and also Cronbach's Alpha value of each factor is more than 0.6 which indicates that the constructs are reliable. Also, these factors collectively explain 66 percent of the study.

Table 3. Mean value of factors

Constructs	Items	Loadings	Average	Construct Reliability
F1	**Security Risk**			
Sec1	I add the product into my cart only but don't buy it for security reasons	0.737	2.864/4=0.716	0.977
Sec 2	I am concerned that the information I submit on the Internet could be misused	0.624		
Sec 3	I doubt that online sites have adequate security features	0.699		
Sec 4	I feel online buying is full of errors and not safe	0.804		
F 2	**Privacy Risk**		5.163/7=0.737	0.976
PVR1	Online retailer asks for a particularly sensitive piece of information	0.786		
PVR2	I feel my credit card information will leak	0.717		
PVR3	I feel that online shopping sites may share my personal information with others for profit motive	0.725		
PVR4	I feel online retailer will keep a record of my purchase priority and frequency and will share it outside	0.712		
PVR5	I am concerned that a person can find private information about me on the internet.	0.728		
PVR6	Online retailers may force me to accept privacy policy without disclosing the facts	0.744		
PVR7	Privacy of my details concerns me	0.751		
F3	**Time Risk**		7.557/10=0.76	0.981
TR1	There is a risk that my product will not be delivered on time when I require it	0.741		
TR2	I may end up with losing my precious time in diverted searches over web stores	0.740		
TR3	Exchanges and returns in online shopping are far much time consuming than that of offline	0.747		
TR4	Comparisons of price waste my important time in online shopping	0.723		
TR5	I feel refund for returned products will be realized very late in my bank account	0.755		
TR6	I may miss the important moment in waiting for the products	0.743		
TR7	Online retailers charge extra for a speedy delivery	0.768		
TR8	I doubt the timely delivery of the products	0.757		
TR9	Important time is lost in logging in to websites	0.767		
TR10	Time is a crucial factor for me while shifting to online shopping	0.816

Regression Analysis

To test the most important risk for potential online shoppers' behavior a stepwise multiple regression analysis was performed as shown in Table 4. Online shopping behavior was taken as dependent variables while Product risk, Privacy risk, Time risk, Social Risk, and Security risk were independent variables. The higher value of the standardized coefficient beta depicts the most contributing risk on which online shopping behavior is dependent. Here in our case value of standardized coefficients, beta is 0.404 for Product risk, 0.241 for Privacy risk, and 0.268 for Time risk, 0.269 for social risk and 0.102 for security risk. Regression equation that shows the impact of risks on the online shopping behavior of potential online shoppers can be given:

Online shopping behavior= .837+ .328 (Product Risk) + .192 (Privacy Risk) + .207 (Time Risk) + .205 (Social Risk) +.084 (Security Risk)

Table 4. Step Wise regression results of identified risks

Independent Variable	Unstandardized Coefficients		Standardized Coefficients	T	Sig.
	B	Std. Error	Beta		
Constant	.837	.085		9.827	.000
Product Risk	.328	.010	.404	31.753	**.000**
Privacy Risk	.192	.009	.241	20.365	**.000**
Time Risk	.207	.009	.268	23.477	**.000**
Social Risk	.205	.009	.269	22.076	**.000**
Security Risk	.084	.008	.102	9.943	**.000**

Dependent Variable: online shopping behavior
Source: Primary data

Mean and Standard Deviation Analysis

Table 5 depicts the mean value and standard deviations of various risks in online shopping. Security Risk (F5) mean ($\bar{X} = 3.3396$) is highest so it is the strongest hurdle that a potential customer feels while thinking of shift to online shopping. Product Risk (F1) is the second-highest influencing factor with mean value ($\bar{X} = 3.2018$) followed by Social Risk (F4) ($\bar{X} = 2.9534$), Privacy Risk (F2) ($\bar{X} = 2.9515$). As the table shows Time Risk (F3) has the lowest mean value ($\bar{X} = 2.9134$) which represent that it is the lowest influencing factor among all the five risks that potential customer feels in online shopping. On the other side, privacy risk had the highest variation because it has the highest standard deviation (σ) with value 0.93984 while product risk shows minimum variability in responses and shows the highest consistency because of lowest standard deviation (σ) with value 0.86327.

All the risks in online shopping were significant for potential online shoppers. So, the online retailer should frame strategies for consumers based on their perceived risks.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Mean value and standard deviation of various risks

Variables	Factors	N	Overall Mean	Std. Error	Std. Deviation	Preference
Product Risk	Product Risk	268	3.2018	.05373	.87959	II
Privacy Risk	Privacy Risk	268	2.9515	.05741	.93984	IV

Source: Primary data

RECOMMENDED STRATEGIES FOR ONLINE RETAILERS

Online retailers should work for improving their measures to protect the privacy of the information that is entered by the customers while entering into a buying process. They should assure customers that any piece of information provided by the customers at the time of purchase will be kept safe. Even there should be pop up or disclaimer by the online retailers containing the assurance of protection of privacy. The privacy assurance policy of the company should be well defined and well communicated to the customers, which in turn will boost the confidence of the potential online shoppers.

Product risk was found yet another concern for potential online shoppers. Surety of delivery of right products, Uploading the real pictures of the product on the sites and matching the image to the original product, avoiding misleading ads, clearly mentioning the guarantee and warranty policies without hidden conditions, Making return policies clear to the customers at the time of billing and making sure that no pirated, defective or wrong product has been delivered to the customers.

As the customers feel risk in delivery time in online retail and for the same, they found offline shopping the best alternative for these issue online retailers must frame strategies. Time risk also included the time lost in the search of desired products, online retailers should make the search of the product easy on the site and also suggesting the products to the customers based on their past purchase history to save their time. Auto order placing can also be the option given to the customers for recurring purchases to save time.

Customers feel that they will lose their status of exclusivity if they will shop online. So somewhere, for some income groups, online shopping is lower their status. Heavy discounts, everyday sales have somewhere shaken the trust of the customers and they directly link it with the poor quality of the products. Online retailers need to keep a check on this point that too many sales are not affecting their positioning.

CONCLUSION

This study identified the risks that significantly influence the potential online buyers to shift from brick and mortar retail to online retail. It was found that potential online shoppers considered Product Risk, Privacy Risk, Time risk, Social Risk and Security Risk to be important while thinking of online shopping. Among all these risks Security Risks was found to be on potential online buyers' mind followed by product risk, social risk, privacy risk, and time risk which stops them from buying online.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The present study adds into the existing knowledge of the policymakers of online retail platforms that they should averse the risks identified in the study by formulating the strategies which are best aligned with the expectations of the potential online buyers.

This study is not free from limitations. As this study was conducted on a limited geographical area of Gurgaon city only, so, it is difficult to generalize the result. Limited time and financial resources acted as a limitation of the study.

FUTURE SCOPE FOR THE STUDY

For further research, a comparative analysis of the risk of potential and existing online shoppers can be performed. Comparison based on demographics can also be done for future research. Further research can be conducted by considering another geographical area.

Chapter 59
Influence Factors of Online Shopping Food Quality Performance Considering the Relationship Quality

Xiaoping Li

Lan Xu
Jiangsu University of Science and Technology, Zhen Jiang, China

ABSTRACT

Most of the existing research relating to online shopping are focused on the analysis of customers' purchase intention and loyalty, but lack influencing factors on the quality performance of online shopping food. This article introduces the relationship quality, and constructs a model of relationship quality, logistics service quality, information sharing, supplier quality management and quality performance. This is done through an empirical study, taking 145 online food businesses as an example. At the same time, the relationship quality not only has an effect on the quality performance through information sharing, logistics service quality and supplier quality management, but also has an indirect effect on quality performance through information sharing and logistics service quality or information sharing and supplier quality management.

INTRODUCTION

With the rapid development of network economy and the acceleration of modern lifestyle, the way of shopping has changed, in addition to the traditional farmers markets, chain supermarkets, small retail stores and other food shopping modes, online shopping has become a new channel for sales of food products in China. According to relevant analysis, the total amount of electricity suppliers of food in China is close to 40 billion Yuan in 2015. The market size of food online shopping will be approximately 140 billion Yuan in 2018. Compare with the traditional sales format, the advantages of online shopping is reflected in the integration of information, capital and logistics trading platform to meet the personalized shopping needs of different customers (Yao, 2015). However, the low thresholds of online food sales, such as the undetermined locations, the lack of formal procedures and other issues, have brought convenience to consumers, but also have led to food safety problem.

The new "Food Safety Law" provides a network food trading platform should require food operators to provide real-name registration and clarify their food safety management responsibilities. The license shall be obtained legally and examined in accordance with the law. Therefore, online shopping businesses are faced with the double pressure as to improve the quality of products and to save production cost for a greater profit. The change of competitive environment is an urgent business to strengthen the management of all aspects from the point of view of supply chain, and to establish the corresponding supply chain quality performance evaluation system. While the scholars have studied the quality performance, the concept of relationship quality has been introduced and a series of studies were carried out. Prajogo & Olhager (2012) found that supply chain relationship quality not only play a direct positive role on performance, but also play a positive role on logistics through the information sharing, and then through the logistics impact on performance.

In view of this, this paper represents the point of view from online shop business in exploring the factors of online shopping food quality performance and the relationship between relationship quality and quality performance under the online shopping. In the food supply chain, it is closely related to the quality of logistics, information flow, and the choice of the correct supplier is the key factors in determining the quality of the product. Therefore, this paper focuses on the supply chain management in the logistics service quality, information sharing and supplier quality management on the impact of online shopping food quality performance, and meanwhile it provides theoretical basis and guidance for the development of online shopping food industry, so as to improve the quality performance of online shopping food industry.

THEORETICAL FOUNDATION AND RESEARCH HYPOTHESIS

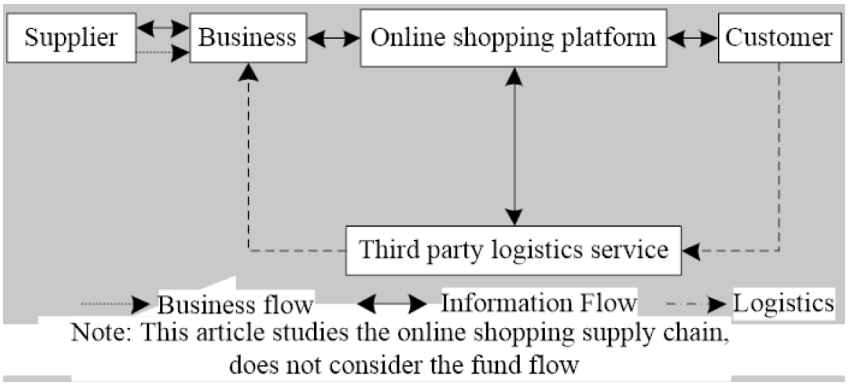
Online Shopping Supply Chain Definition

Lu et al. (2015) proposed that the online shopping supply chain is a multi-level sales and distribution network which is formed by the supplier, the online shop (business), third-party logistics service providers and customers. It is a specific process which includes supplier supply, merchant sales, customer online orders, electronic payment, express logistics and transportation, receiving, payment, return and evaluation feedback and a series of activities. In this paper, the online shopping supply chain mainly consists of five participants: suppliers, online shop (business), third-party logistics service providers, customers and the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

online shopping platform. The supplier will be responsible for supplying the goods to shop. Online shop makes a sale in E-commerce platform as a business. Third party logistics enterprises are responsible for the delivery of goods to customers. Customer who has online shopping terminals and composed of distribution in the world is responsible for the receipt of goods. Online shopping platform is the core of the online shopping supply chain, and the supply chain factor flow is not involved in the elements of transfer directly. Its role is to connect each function node and to collect transaction information service for all. The online shopping platform of this article refers to the third-party E-commerce model, which is represented by Taobao, PaiPai, eBay, etc., and belongs to the C2C E-commerce platform model. The structure of online shopping supply chain is shown in Figure 1.

Figure 1. Online shopping food supply chain structure



Relationship Quality and Logistics Service Quality

Service quality is deemed as a prerequisite for the relationship quality which has been endorsed by many scholars. The research of logistics service quality under service quality subset on relationship quality is also attracted the attention of scholars, but few scholars have studied the effect of relationship quality on the logistics service quality. In fact, high-quality supply chain relationship can reduce transaction costs and increase the value of logistics service. Panayides & So (2005) found that relationship quality has a significant positive impact on the logistics service quality through large-scale industrial survey data. In order to explore the impact of relationship quality on the logistics service quality, this paper uses the relationship quality as the pre-variable, and makes the following hypothesis:

H1: Relationship quality has a positive impact on logistics service quality.

Relationship Quality and Information Sharing

Researchers generally believe that the supply chain relationship has a significant impact on information sharing. When the relationship among supply chain partners is closer, the degree of information sharing will be greater. Fu & Lin (2014) found that trust and relationship commitment have significant positive effect on information sharing from the perspective of the company and farmers. Ye & Xue (2012) dis-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

covered that the relationship commitment has a significant positive impact on the quality and the content of information sharing through questionnaire survey of 273 manufacturing industries. Therefore, this paper puts forward the following hypothesis:

H2: Relationship quality has a positive effect on information sharing.

Relationship Quality and Supplier Quality Management

With the increase of external resource dependence, enterprises begin to develop a close relationship with major suppliers. The intimate relationship can encourage the suppliers to participate in the design of food quality effectively, to improve the quality of food and the stability of the process so as to reduce the cost of enterprise's quality, and improve the qualified rate of food. Enterprises and suppliers who maintain a stable and sustainable relationship is conducive to the production, delivery quality and reduce transaction costs and have other aspects of the advantage. Zhang et al. (2013) has suggested that the supply chain relationship quality has a positive impact on the supplier quality management in the supply chain management. Therefore, this paper puts forward the following hypothesis:

H3: Relationship quality has a positive effect on supplier quality management.

Information Sharing and Logistics Service Quality

The normal operation of the supply chain cannot be separated from the support of information and logistics, information is the basis of maintaining the normal operation of the supply chain, especially in the food supply chain when the improvement of the level of information sharing plays an important role in the logistics service quality. High quality information sharing is conducive in improving the whole logistics supply chain responsiveness and response capacity, and thus improving the logistics service quality, timeliness and so on. Carr & Kaynak (2007) stated that effective communication can improve the service quality through information sharing. Dai et al. (2015) have taken on 130 logistics enterprise users as the object of investigation and shown that information sharing has a significant positive impact on the logistics service quality. Therefore, this paper puts forward the following hypothesis:

H4: Information sharing has a positive impact on the logistics service quality.

Information Sharing and Supplier Quality Management

The information and knowledge transfer among supply chain partners can promote the timeliness and effectiveness of business contacts, and improve the quality of service of the supplier. Hsu et al. (2008) have identified that information sharing has a positive effect on supplier quality through the empirical and multiple regression analysis. Jiang & Li (2014) believed that through exchanging information between enterprises and suppliers is advantageous to the development of new products and promote the supplier's attention to the quality of products. Therefore, this paper puts forward the following hypothesis:

H5: Information sharing has a positive impact on supplier quality management.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Logistics Service Quality and Quality Performance

The management of logistics service quality is beneficial in improving the overall interests of the whole supply chain and reducing the influence of uncertainty factors. The improvement of quality performance and high-quality logistics services are integrated closely. Stank et al. (2003) have proved that the logistics service quality can affect the performance directly. It can be seen as that high level of logistics service quality can bring higher product quality performance for the enterprise. Therefore, this paper puts forward the following hypothesis:

H6: Logistics service quality has a positive impact on quality performance.

Information Sharing and Quality Performance

Information sharing is the key to obtain and maintain competitive advantage, and is also the base of realizing supply chain management. Therefore, the enterprises between upstream and downstream of supply chain through information sharing can reduce the bullwhip effect, and improve the quality of performance of supply chain. Koçoğlu et al. (2011) have said that information sharing has a positive effect on performance in the study of supply chain integration on the role of information sharing. In order to discuss the relationship between information sharing and quality performance, this paper puts forward the following hypothesis:

H7: Information sharing management has a positive impact on quality performance.

Supplier Quality Management and Quality Performance

Quality is the survival of the enterprise, supplier quality management activities not only affect the operating conditions of enterprises, but also affect the entire supply chain operating performance. Enterprises and suppliers who establish a long-term and stable cooperative relations would make a greatest contribution to the performance quality. Kaynak & Hartley (2008) have found that supplier quality management and performance has a positive relationship. Zhang et al. (2013) have demonstrated that the supplier management has a significant positive impact on the quality of agricultural products. Therefore, this paper puts forward the following hypothesis:

H8: Supplier quality management has a positive impact on quality performance.

According to the above analysis, this paper designs the model in Figure 2.

RESEARCH DESIGN

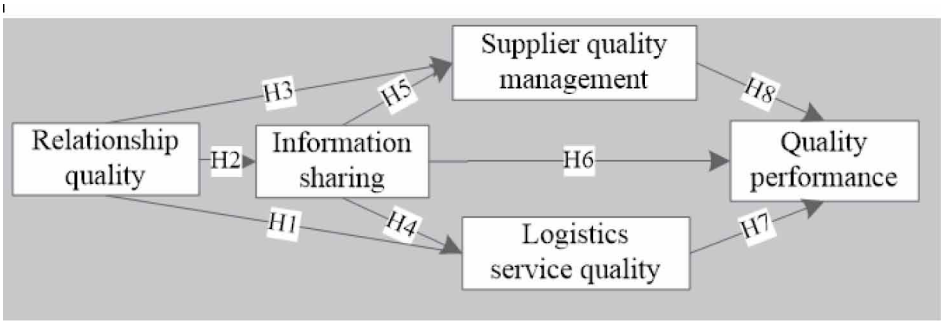
Sample Description and Investigation

This questionnaire is mainly aimed at the business of food store on the electronic commerce platform. It mainly consists of two parts. The first part is the basic situation questionnaire, including personal

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

position, the nature of the shop, the number of staff, sales of food types, the complaint rate and so on. The second part is the main part of the questionnaire, that is, factors affecting the quality performance of online shopping food. The main questionnaire methods were e-mail and telephone, with survey duration from February 2016 to June 2016. A total of 235 questionnaires were issued, the actual recovery was 182 questionnaires, and among them, 37 results have to be removed as they were omitted or contradictory answers obviously, and 145 questionnaires were returned. The effective rate of the questionnaires was 60.9%.

Figure 2. Hypothesis model



Variables Measurement

In order to assure the reliability and persuasiveness of the test scale, this study selected the domestic and foreign scale as matured as possible. Among them, the measurement scale of relational quality was mainly using the research results of Fynes et al. (2004) for reference, and selected four dimensions including trust, commitment, cooperation and relationship atmosphere with a total of 12 measurement items.

Combined with the reality of logistic of online food shopping, logistics service quality is based on five dimensions including integrity, timeliness, responsiveness, convenience and reliability with a total of 5 measurement items. Information sharing refers to the dimension of Li & Lin (2006), which is divided into the content of the information sharing and the quality of the information sharing, a total of 6 measurement items. According to the dimension of Miao (2015), the supplier quality management is divided into three dimensions: supplier involvement, supplier cooperation and supplier evaluation, a total of 3 measurement items. According to the study of the internal quality performance of Song et al. (2011), the division of quality performance has selected the 3 indexes of durability, reliability and pass rate. With the external quality performance of Voss & Fynes (2002), this paper selected quality, customer satisfaction and the delivery quality of 3 indicators, a total of 6 measurement items. Questionnaire answers were compiled using the Likert 5 scale. Respondents were required to know the shop profile and responded by the current actual operating conditions of the shop. The "1" in the questionnaire means disagree strongly. "2" means disagree and so on, until "5" means agree strongly. After the initial preparation of all the measurement scales, we select the relevant personnel for a small sample of the test, then modify the form of expression and processing of the questionnaire items so as to compile the final formal questionnaire.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

DATA ANALYSIS AND TESTING

Reliability and Validity Test

1. **The reliability test:** In this paper, the Smartpls software is used to analyze the validity of the questionnaire and the validation model by partial least squares regression. In order to ensure the accuracy of the data, reliability and validity of the samples are needed to be tested. As shown in Table 1, the lowest coefficient is 0.783 and the combined reliability CR is 0.873, which is greater than 0.7, indicating that the sample variables have good reliability and internal consistency;
2. **The validity test:** The converge validity and discriminant validity of construct validity were being deployed in this paper. The convergent validity should be tested by cross-loading value, that is, the load on each item is greater than the load on other factors, and all the AVE values are greater than 0.5. From the section in bold of Table 2, we can see that the questionnaires are tested by the validity of polymerization. In the PLS algorithm, the AVE value is mainly adopted to verify the discriminant validity, that is, the AVE value of each variable is obtained by the square of the numerical value, and the AVE value of the square root must be greater than 0.5. From table 3 we can see that the discriminant validity of each variable is good.

Table 1. The reliability of variable table

Latent Variable	Number of Measurements	Cronbach's α	CR
Relationship quality	12	0.920	0.932
Logistics service quality	5	0.852	0.894
Information sharing	6	0.860	0.896
Supplier quality management	3	0.783	0.873
Quality performance	6	0.845	0.884

Structural Model Validation

The model was validated by using the PLS-based bootstrapping algorithm, which included the standardized path coefficient, the determination coefficient (R^2), and the significance level, the results are shown in figure 3. It can be seen that both the logistic service quality and the information sharing value of R^2 are greater than 0.35, and the R^2 of supplier quality management and quality performance are also close to 0.35, which indicates that the model has a good fitting effect.

When P is equal to 0.05, the T value of each path is greater than 1.96, the structural equation model has a preferable predictive effect. Specific results are shown in Table 4.

From Table 4, we can see that all the assumptions of this paper are tenable. Among them, H1, H2, H4, H5 in $p < 0.001$ significantly. H3, H6, H7 in $p < 0.05$ significantly. In light of this, we can know that this model can well reflect the influence factors of online shopping food quality performance.

CONCLUSION

Through the above research, we can obtain the following conclusions:

1. The relationship quality has positive influence on information sharing, logistics service quality and supplier quality management. This indicates that the relationship quality among supply chain partners can improve the reliability and authenticity of the information sharing. It is conducive in achieving the efficient operation of logistics, promoting the supplier quality management, and improving the quality of food suppliers. Businesses should deal with the relationship among supply chain members reasonably, maintain the relationship quality among supply chain members through trust, commitment, and so on, as well as promote long-term and stable cooperative relationship among supply chain partners. For that reason, businesses can sign contracts with partners, not only conducive to the establishment of a more lasting, close cooperative relationship, but also conducive to improve the quality of the store's food quality performance;
2. Information sharing has a positive impact on logistics service quality and supplier quality management. By strengthening the management of the third-party logistics service quality, the business can master the real time information of the logistics service, which is beneficial to improve the logistics service quality of the shop. Through information sharing, businesses can adjust their sales according to market changes and the number of products, and form an effective control on the product quality of the supplier. They should strengthen the internal information network platform construction, establish advanced partner management information system with suppliers and third-party logistics enterprises, improve the efficiency and frequency of information exchange, and ensure the seamless communication between supply chain partners;
3. Logistics service quality, information sharing and supplier quality management have a positive impact on quality performance. This means that the logistics service quality, information sharing and supplier quality management determine the performance of food quality of shops, businesses should strive to improve the level of information sharing, third-party logistics service quality and supplier quality management level to promote shop quality performance;
4. From the path analysis of the model, we find that the relationship quality not only have an effect on the quality performance through information sharing, logistics service quality and supplier quality management, but also have an effect on food quality performance through information sharing and logistics service quality or information sharing and supplier quality management indirectly. It shows that the relationship quality can play a role in the quality performance through multiple paths.

This paper mainly discusses the factors influencing the online food quality from the perspective of online food businesses, and constructs the model of impact of information flow, logistics and supplier quality management on quality performance. The results of this study enrich and improve the theoretical system of online shopping food supply chain, which have important practical significance on Chinese online shopping in the food industry. In addition, this article also has shortcomings: without considering the quality of business and online shopping platform relationship, we will study the impact of online shopping platform on food quality performance of online shopping further in the future.

Chapter 60
Relationships Among Dimensions of Online Second-Hand Shopping, Satisfaction, and Repurchase Intention

Murali Swapana
VIT Business School, VIT University, Vellore, India

Chandrasekaran Padmavathy
VIT Business School, VIT University, Vellore, India

ABSTRACT

The purpose of this study is to examine the relationships among dimensions of online second-hand shopping, customer satisfaction, and repurchase intention. Responses obtained from 608 Indian online second-hand shoppers show that the dimensions of online second-hand shopping such as price, website quality, nostalgia, and brand image influence customer satisfaction. In addition, customer satisfaction positively affects repurchase intention. Findings of the present study provide intuitive guidelines for online second-hand marketers in approaching emerging markets through effective online shopping strategies.

INTRODUCTION

E-commerce research has gained momentum among academicians and practitioners over the past few years. Online second-hand retail market is the most interesting expansion of e-commerce industry (Belk, Sherry, and Wallendorf, 1988; Roux and Guiot, 2008; Sherry, 1990a; Soiffer and Herrmann, 1987). It provides huge opportunities for sellers and buyers. Buyers are able to compare products through online platform and sellers are able to post advertisements online and communicate easily with the prospective buyers (Kamoun and Halaweh, 2012; Kumar, Sikdar, and Alam, 2016; Sherry, 1990b).

Globally, online second-hand retail market is spearheading. In India, online second-hand retail industry has been growing over the past years (Snigdha, 2016). For example, Indian households have progressed dealing with second-hand goods worth of 1, 15, 000 crore in 2015 from 60,000 crore in 2011 (Chitra, 2014). Today's economic condition fuels the demand for purchasing second-hand products. Importantly, middle and lower income people buy second-hand products to satisfy their needs in a cost-effective manner. People who count on time and money are the most prospective buyers to engage in second-hand shopping (Kwon and Lennon, 2009; Williams and Paddock 2003). However, customer retention stands as a major concern for online retailers and sellers who wish to develop and maintain customer relationships (Sharkey, Scott and Acton, 2010). Customer retention is four times profitable than acquiring a new customer (Fang, Chiu, and Wang, 2011). Hence, it is crucial to determine the key factors that affect customer's intention towards repeat purchase of second-hand products.

Thus, the purpose of this study is to examine the effect of online second-hand shopping dimensions on customer satisfaction and customer retention. Specifically, this study aims to test the relationships between price, website quality, nostalgia, and brand image on customer satisfaction and effect of customer satisfaction on customer retention. The rest of the paper is structured as follows. The next section provides hypotheses development followed by research methodology. Finally, we present discussion, implications and future research directions.

Hypotheses Development

This study hypothesizes that price, website quality, nostalgia and brand image have a positive influence on customer satisfaction and customer satisfaction will positively affect customer retention. Customer retention refers to the probability that a customer will continue to purchase second-hand products from the same website in future (Chiu et al., 2012). Figure 1 shows the research model of the study.

Price

Price represents a sum of money that customers give to acquire a particular product (Zeithaml, 1988). Customers use price as a quality-signalling cue that indicates "you get what you pay for" (Erickson and Johansson, 1985). Customers have a propensity to compare the prices and then adopt the one which suits their situation (Abu-shamaa et al., 2016; Bojanic, 1996; Kim et al., 2012; Yoon, et al., 2014). In online second-hand consumption, price is the most influencing dimension as many rare products are available for lesser price. Fair price strategy helps the second-hand sellers to attract buyers and achieve buyers' satisfaction. Therefore, we hypothesize that

H_1: There is a positive relationship between price and customer satisfaction.

Website Quality

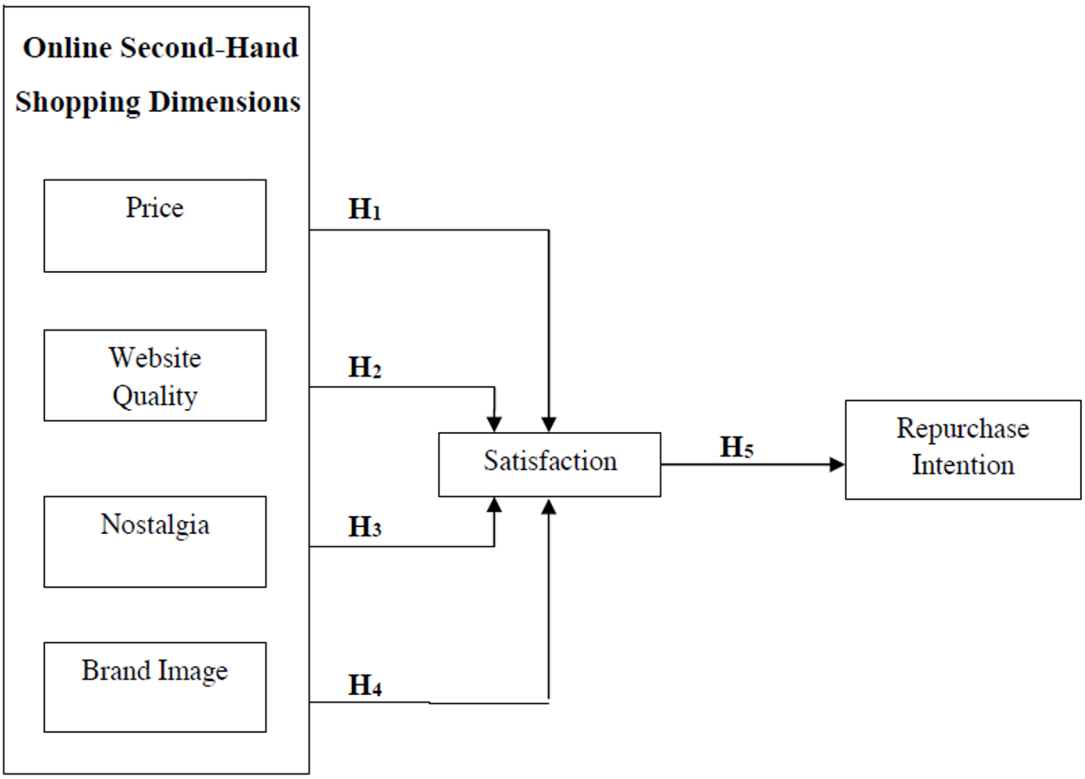
Website quality refers to the extent to which it presents sufficient and relevant information about the products being promoted (Law and Bai, 2008). Website plays a major role in online retail industry because it is the only way to communicate with the customers (Chang and Chen, 2008). It's a platform for efficient and effective information and services (Yates, 2005). Online retailers must pay attention to website design to ease customer search for information and payment. Poor website design may lead

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

to less chance of customers' repeat purchase (Lin, 2008). Online shoppers will tend to repurchase if a particular website has greater functionality (Maamar et al., 2009). Hence, we hypothesize that

H_2: There is a positive relationship between website quality and customer satisfaction.

Figure 1. Research Model



Nostalgia

Belk et al., (1989) explain second-hand shopping as a way of obtaining exclusive products. Online second-hand market stimulates the consumers by offering exclusive recreational provisions (Leonard-Barton, 1981; Stone, Horne, and Hibbert, 1996). Consumers who tend to have a high return on their income prefer online second-hand shopping (Williams and Paddock, 2003). In addition, people who look for unique and old objects adopt second-hand shopping (Gregson and Crewe, 1997; Kopytoff, 1986). In short, online second-hand shopping is the method of interlinking hedonic and economic phases (Bardhi and Arnould, 2005; Sherry, 1990a). Therefore, we hypothesize that,

H_3: There is a positive relationship between nostalgia and customer satisfaction.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Brand Image

Brands have a major role to play while making a purchase decision (De Chernatony and McDonald, 2003; Keller, 2007). Brand image enables sellers to generate more profit by attracting more number of customers (Delgado and Herna´ndez, 2008; Rubinstein and Griffiths, 2001). Many studies find a positive relationship between brand image and customer satisfaction (eg., Hahn and Kim, 2009; Ibeh et al., 2005). As sellers advertise branded second-hand goods (Liu, Eng and Sekhon, 2014), we hypothesize that

H_4: There is a positive relationship between brand image and customer satisfaction.

Satisfaction

Satisfaction is an affective state that emerges from emotional reaction to a particular product or service experience (Spreng, MacKenzie, and Olshavsky, 1996). In this study, satisfaction is an evaluation and fulfilment of performance based on prior experience with online second-hand shopping (Hellier et al., 2003; Jones, Mothersbauch, and Beatty, 2000). Previous empirical findings indicate that satisfaction positively influence customers' repurchase intention (Anderson and Sullivan, 1993; Fornell, 1992; Patterson and Spreng, 1997; Selnes, 1998). Further, online purchase satisfaction increases repeat purchase behaviour (Amoroso and Ogawa, 2013; Anderson and Srinivasan, 2003). Hence, we hypothesize that

H_5: Customer satisfaction will have a positive influence on repurchase intention.

METHODOLOGY

Sample and Data Collection

To empirically test the model proposed in Figure 1, we collected data from online second-hand shoppers. Questionnaire was posted with hyperlink on a number of relevant Facebook pages. Customers with online second-hand shopping experience were invited to participate in the survey. The returned questionnaires were screened for usability and as a result 608 responses were found to be complete and valid for data analysis.

Measurements

To ensure content validity, all the items were adopted from existing literature. Items for measuring price, nostalgia, website quality, brand image, customer satisfaction, and repurchase intention were adapted and modified from Guiot and Roux (2010); Min et al., (2009); Pappas et al., (2014); Roux, and Guiot, (2008). All the items were measured on a five-point Likert scale ranging from 5 'strongly agree' to 1 'strongly disagree'. Demographic profile of the respondents including gender, age, education, occupation, income and experience in online second-hand shopping were also captured. Table 1 presents the demographic profile of the respondents. Table 5 in Appendix A lists the items.

ANALYSIS AND RESULTS

Exploratory Factor Analysis

An exploratory factor analysis (EFA) using varimax rotation was performed on the dimensions of online second-hand shopping to identify the underlying factor structure. We deleted certain items based on factor loadings (<.5), cross loadings (<.4) (Hair et al., 1998) and reliability (<.7) (Nunally, 1978). Final EFA resulted in 76.9% of the total variance with four factors. The items had communalities ranging from 0.66 to 0.84 with each item loaded strongly on one factor. Cronbach's alpha for each construct was calculated to ensure internal consistency among the items. Alpha for Price = 0.91, Website Quality = 0.92, Nostalgia = 0.90, Brand image = 0.85, customer satisfaction = 0.93, repurchase intention = 0.93 and combined reliability was high enough with alpha value as 0.96. All the alpha values were above 0.7 and thus exceeded the cut-off value recommended by Nunally (1978).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Measurement model results

Constructs	Items	Loadings	p Value	Alpha	AVE	Composite Reliability
Price	PR1	0.88	***	0.91	0.78	0.93
	PR2	0.90	***			
	PR4	0.88	***			
	PR5	0.88	***			
Nostalgia	NT1	0.83	***	0.90	0.78	0.93
	NT2	0.88	***			
	NT3	0.91	***			
	NT4	0.90	***			
Website Quality	WQ3	0.86	***	0.92	0.80	0.94
	WQ4	0.91	***			
	WQ5	0.91	***

	ST3	0.92	***			
	ST4	0.90	***			
	ST5	0.89	***			
Repurchase Intention	RP1	0.89	***	0.93	0.79	0.95
	RP2	0.91	***			
	RP3	0.90	***			
	RP4	0.88	***			
	RP5	0.85	***			

Measurement Model

We evaluated measurement model based on reliability, convergent and discriminant validity using Smart PLS 3.2.6. First, reliability was examined using composite reliability (CR) values. Results showed that the values of CR range from 0.90 to 0.95, exceeding the threshold value of 0.7 (Hair et al., 1998), confirming construct reliability. Second, convergent validity was tested using two criteria: indicator loadings and average variance extracted (AVE). The results showed that all the factor loadings exceed 0.7 and the AVE values range from 0.70 to 0.80, indicating that convergent validity is achieved (Table 2). Third, discriminant validity was tested using the criteria mentioned by Fornell & Larcker (1981) that the square root of AVE should be greater than all the inter-construct correlations. The results indicated that square root of AVE is greater than inter-construct correlations and thus discriminant validity is achieved (Table 3).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Discriminant Validity

Constructs	1	2	3	4	5	6
Price	**0.88**					
Nostalgia	0.51	**0.88**				
Website Quality	0.64	0.58	**0.90**			
Brand image	0.58	0.54	0.63	**0.83**		
Satisfaction	0.64	0.60	0.79	0.67	**0.89**	
Repurchase Intention	0.67	0.58	0.64	0.66	0.74	**0.89**

Note: The diagonal elements are the square root of AVE & the off-diagonal elements are the values of inter-construct correlations

Structural Model

Given a valid and reliable measurement model, we evaluated the inner model by employing bootstrapping. The results of structural model indicated that all the four dimensions of online second-hand shopping significantly predict customer satisfaction, supporting H_1, H_2, H_3, and H_4. Further, customer satisfaction has significant positive effect on repurchase intention, supporting **H_5:** Table 4 shows structural model results.

Table 4. Structural model results

Hypothesized paths			*t*-value	*p*-value	Hypotheses
Satisfaction	<--	Price	2.98	0.003	Accepted
Satisfaction	<--	Website Quality	10.79	***	Accepted
Satisfaction	<--	Nostalgia	3.64	***	Accepted
Satisfaction	<--	Brand image	6.06	***	Accepted
Repurchase Intention	<--	Satisfaction	34.47	***	Accepted

*** statistically significant at $p < 0.001$

DISCUSSION AND IMPLICATIONS

Despite numerous researches on online shopping, only few studies have examined factors influencing customers' online second-hand repurchase intention (Roux and Guiot, 2008). This research has contributed to online second-hand retail literature in two ways. First, this study has developed and tested a model containing the relationships among dimensions of online second-hand shopping, customer satisfaction, and repurchase intention. Second, to the best of our knowledge, this is the first study to identify factors influencing online second-hand repurchase intention in the context of Indian online second-hand retailing.

The results of the study showed that price significantly affects satisfaction, supporting H_1. This is in line with previous studies in which price predicts online customer satisfaction (Williams and Paddock, 2003). Price refers to fair pricing of products that sellers quote in online second-hand platform. Next, we found positive impact of website quality (H_2) on satisfaction, which is consistent with previous

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

studies. For instance, Chen et al., (2010) and Liu et al., (2000) find that website functionality improves customer satisfaction. Website quality enables customers to search for products easily and to transact safely. Significant positive effect of nostalgia on satisfaction (H_3) reveals that customers choose online second-hand market to buy unique and antique products. Finally, we found positive effect of brand image on customer satisfaction (H_4). Selling branded second-hand goods under various product categories lure the buyers to purchase the product and improve satisfaction levels. Further, this study found a positive and significant effect of satisfaction on repurchase intention (H_5). Increased levels of satisfaction make the customers to repurchase products in future.

The study provides certain practical implications for online second-hand retailers. The positive effect of online second-hand shopping dimensions on customer satisfaction indicates that customers get satisfaction from e-commerce websites when they find antique products, effective user interface of websites, comparable and reasonable pricing, and branded products. This implies the retailers to encourage sellers to post vintage products and branded goods that are reasonably priced. It is important for retailers to have appealing website design. Specifically, online retailers can constantly update their website and adapt user-friendly design for easy search of products and safe transaction to improve customer satisfaction levels. They can include unique and old products in the product portfolio to attract nostalgic customers. They can encourage sellers to advertise branded second-hand products with a rational price to attract more buyers and to satisfy their needs on second-hand shopping.

LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

This research has certain limitations. First, the hypothesized relationships were tested using a cross-sectional research design. To enhance the generalizability of the findings, longitudinal research should be used by future researchers to test the research model. This study is based on Indian population and future studies can use data from other culture to generalize the findings. Second, other variables such as bargaining power, convenience, and personality can also be studied as antecedents of customer satisfaction. Third, future studies can examine other customer outcome variables such as cross-buying, impulse buying, and word-of-mouth communication (Agag and Masry, 2016; Kuo et al., 2012; Li, Browne, and Wetherbe, 2006; Samuel, Balaji and Wei, 2015). Finally, this study tested the effect of dimensions of online second-hand shopping on satisfaction and effect of satisfaction on repurchase intention. Future studies can determine the mediating effect of satisfaction between online second-hand shopping dimensions and repurchase intention.

APPENDIX

Table 5. Items used in the Questionnaire

S.no	Measurement items
1.	**Price (Roux and Guiot, 2008; Guiot and Roux, 2010)**
	By shopping second-hand, I feel I'm paying the right price for things
	I can afford more things because I pay less in second-hand
	It's often not worth paying more to get something new*
	I don't want to pay more for a product just because it's new
	One can have more things for the same amount of money if one buys second-hand
2.	**Website Quality (Gehrt et al., 2012)**
	My online second-hand shopping website is user-friendly*
	My online second-hand shopping website is easy to access*
	My online second-hand shopping website is easy to search for products
	I like the functionality of my second-hand shopping website
	My second-hand shopping website performs effectively
	I like the features of my second-hand shopping website
3.	**Nostalgia (Roux and Guiot, 2008; Guiot and Roux, 2010)**
	I'm much more attracted by old things than by new things
	I like buying second-hand objects because I find them authentic
	I love buying second-hand objects because they evoke the past
	Above all, I buy second-hand articles because they're old and have a history
	I like buying second-hand mainly for old objects*
4.	**Brand (Alam, 2015)**
	I tend to buy a second- hand product if it is a recognized brand*
	I'm willing to pay a higher price if the second-hand product is a well-known brand
	I'm more interested in buying branded second-hand products
	Second-hand product's age does not matter if it is a well-known brand
	Brand name is an important factor for me in second-hand product purchase
5.	**Satisfaction (Pappas et al., 2014)**
	I am satisfied with online second-hand shopping
	I am pleased with online second-hand shopping
	I feel fulfilled by shopping second-hand products through online
	I feel that second-hand shopping through online is satisfactory
	My feeling with second-hand shopping through online is good
6.	**Repurchase intention (Pappas et al., 2014)**
	I will continue using online platform for shopping second-hand products in the future
	I have a strong intention to go for online second-hand shopping in the future
	I will regularly use online platform for buying second-hand products in the future
	My intention to buy second-hand products through online is high
	If I were to buy second-hand products, I would consider buying it from an online platform

Boris Šantić
First School of Economics Zagreb, Zagreb, Croatia

Ivan Novak
Faculty of Textile Technology, University of Zagreb, Zagreb, Croatia

ABSTRACT

The purpose of this article is to explore the perception of consumers regarding electronic commerce as a tool for sports footwear purchasing. Based on secondary sources, firstly, the authors define e-commerce and discuss its advantages and disadvantages. Then, the results of the empirical research are presented with the aim of (1) determining consumer perception of electronic commerce in the area of this specific product group, and (2) determining the difference between two generations of consumers. Two relevant age groups are compared: the younger population (18-39 years) and middle-aged consumers (40-59 years). The study was conducted on a sample of 202 respondents, of whom 110 are members of the young population and 92 are members of the middle age population. This research empirically confirmed that there are significant differences between generations when it comes to attitudes towards electronic commerce, thus this paper filling the existing gap in modern literature in retail and electronic commerce fields.

INTRODUCTION

Electronic commerce has been expanding over the last few years, and from one of the most unusual forms of trading it has become one of the leading business operation models, especially among business entities. At a time when laptops, smartphones and Internet-enabled tablets are widely and commonly used

technologies, we can expect that gathering information about products, ordering products or services, and digital sales or purchasing activities are the common way of doing business in this digital environment. This is the fact, no matter of types of products sold and distributed.

Knezevic et al. (2017) claim that intermediaries/traders should provide efficient distribution of goods and services, contributing to the whole trade process keeping in mind aforementioned trends. Retailers should use those market drivers that will provide the sale using basic sales activities, elements, skills and forces that persuade consumers to buy products and pay for it at a desirable level of price suiting their channels to new consumer trends. Because 91% of Croatian citizens use the Internet to collect information on products and services (according to Croatian Ministry of Economy, 2017), trends in sales and production should follow market forces within various industries and for various types of products.

In this paper, we are dealing with a specific product group, i.e. "sports footwear", because of its current worth and growing trends within this particular market. Euromonitor (2014) describes continuous growing trends in the footwear market since 2012. In addition, Global Market Insight (2018) claim that the athletic footwear market size was US $80 billion in 2015 and is forecasted to grow at a compound annual growth rate of approximately 3% in the period from 2016 to 2023. Global shipments within this market were over 3.5 billion units in 2015 (according to Global Market Insights, 2018). Euromonitor (2014) shows the structure of the footwear market according to two criteria – gender and age of consumers. It further shows that women's footwear still dominates sales in the general global footwear market.

The global market size of sports footwear is also rapidly growing due to the trend of using footwear products not only for professional sport purposes and trainings, but also for recreation, leisure time and other purposes. This massive trend started some time ago, when sports products, including sports footwear, were labeled "athleisure," a portmanteau comprised of "athlete" and "leisure." Key drivers of athleisure are: "Luxury goods heavy weights join in the wellness and experience trends", "Health is new wealth" and "Wellbeing driven by millennials" (as discussed by Euromonitor, 2017). More and more people are motived by increased awareness regarding a healthy lifestyle, more leisure time, efficient supply chains and increased purchasing power (rise of global spending on luxury goods and healh and fitness), and are willing to purchase all kind of athleisure products including sports footwear. Moreover, Euromonitor (2017) states that athleisure is still going strong and will begin to evolve into a more sophisticated trend, influencing multiple categories and industries. Therefore, sports footwear products with usage for other purposes (i.e athleisure) are a fast-growing trend that will make a significant impact, not only in growing numbers, but also through multiplier effects on complementary industries. Consequently, the athletic footwear market is expected to witness significant growth due to rising disposable income, increasing awareness about healthy lifestyle, demand for comfortable and innovative footwear, and the growing e-commerce retail market (Grand View Reserarch, 2013).

Internet purchase of sports footwear has potential and space for significant increase as well. Namely, market trends analysis and estimations show that the world market for sports footwear will grow both in traditional and in digital channels (see more details in Knezevic et al., 2017). Purchases of sports footwear are expected to increase accordingly in both sales channels. Because of the present and future role and significance of e-retail for purchase of footwear, it is essential to carry out primary research for specific product types in order to better understand consumer preferences for this particular commodity in different age groups.

Although consumer behavior varies significantly depending on the type of product being purchased, there are some studies dealing with apparel or shoes in classical sales channels (Rachulan et al., 2015; Rocha et al., 2005; Seock & Salus, 2008; Moschis et al., 2011). Hovewer, there is a lack of research ex-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

plaining consumer behavior and differences among various consumer groups within online sales channels for sports footwear particularly. In addition, within the current e-commerce literature particular product groups are not sufficiently addressed nor explored. Therefore, the purpose of the paper is to fill in this gap and to explore e-commerce benefits and obstacles perceived by consumers, focusing on examination of differences in attitudes between consumer generations for a particular group of products that shows growing market trends, i.e. sports footwear.

This paper is divided into two parts. The first part gives an overview of literature in the field of electronic commerce (with an emphasis on its advantages and disadvantages from the consumers' point of view) and an overview of the literature in the field of age-related consumer research. The second part of the paper gives the results of the primary research conducted by a questionnaire method applied to two groups of consumers (a) younger consumers (18-39 years) and (b) middle-aged consumers (40-59 years). The results obtained relative to electronic commerce within the area of sports footwear will be compared between these two age groups. Furthermore, statistically significant differences between consumers' groups in perceiving the advantages and disadvantages of e-commerce for this specific product type will be determined.

LITERATURE REVIEW

E-Commerce Definition and E-Commerce Acceptance in Croatia

Different sources give different definitions of electronic commerce that sometimes vary significantly. Laundon & Traver (2015, p. 49) define e-commerce as "the use of the Internet, the World Wide Web, and mobile applications to transact business. More formally, digitally enabled commercial transactions between and among organizations and individuals". Panian (2000) defines electronic commerce as a "process of buying, selling or exchanging products, services or information through a publicly available computer network, the Internet, which offers a great possibility to decrease costs and shorten transaction time." Chaffey (2014, p. 12) claims that e-commerce is "all electronically mediated information exchanges between an organization and its external stakeholders".

Electronic commerce can be defined in a narrower and a wider sense. In the narrow sense, e-commerce represents the digital conduct of the purchase and sales process and the associated transfer of products, services, information and money through computer networks (including the Internet). Some authors also include all sales promotion activities supported by computer networks before and after purchasing, while others point out that individuals, but also private and public organizations can participate in sales transactions. However, accepting Internet technologies and introducing electronic commerce is an inexpensive way of doing business that enables small and medium-sized businesses to compete with multinational companies on the global market (Delić & Knežević, 2012).

Srića & Müller (2001) illustrate e-commerce and e-business as an iceberg where on the top, easily observable part is e-commerce in the narrower sense. That means utilization of digital platforms to sell goods and services to consumers. Under the surface, the larger part of the iceberg depicts all other forms of e-business or internal digital processes supporting various business activities. The hidden part of the iceberg digitally interfaces a certain company towards various customers (both industrial buyers and final consumers), suppliers, government institutions, banks and insurance companies, etc. Turban et al. (2015, p. 7) claim that some authors do not make a distinction between the terms e-commerce and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

e-business. E-commerce, in wider sense, comprises commercial activities and activities that support the sales process, but also e-learning, online cooperation and other digital business activities.

If we discuss forms of e-commerce, we distinguish pure e-commerce and partial e-commerce. (Segetlija et al., 2011, pp. 453). Pure e-commerce requires all digital dimensions to be achieved: the product has to be digital, the sales process has to be digital, as well as payment and delivery. Therefore, examples of the pure e-commerce are online shops for digital music and digital videos, downloadable computer games or applications, electronic books, etc. If one of those dimensions is not digital (product, sales process, payment or distribution), we are in the field of partial e-commerce. As examples of partial e-commerce, we can outline online bookshops that deliver physical books to their customers, online purchasing of apparel and shoes, online travel reservations, etc. In these examples, a part of sales process is done online, i.e. in the virtual world, while goods and services are delivered in the real, i.e. physical, nondigital world.

Panian (2002, pp. 60-61) outlines socially positive and socially negative implications of e-commerce. Positive implications are: quick data access, costless document transformation, openness of information space, the possibility to easily create datasets and efficient data analysis, improved pre-shopping data analysis of products and services, quicker exchange of knowledge and skills utilization, improved collaboration and accessible expertize. On the other hand, socially negative implications of e-commerce are in correlation with the level of risk from technology misusage. Risks of e-commerce according to Panian (2002, p. 61) are: questionable data safety and security, exposed data privacy, endangered personal privacy, lack of control in commercial transactions (both at company and government levels), and jeopardized national interests in conditions of rapidly increasing international exchange.

The data for electronic commerce at the company level, presented by the Croatian Ministry of Economy (2017), show that e-commerce in Croatia generates 44 billion EUR in segment GDP from foreign companies, which is 10.295 EUR per capita. Moreover, 18% of the total retail sales in Croatia is Internet shopping (online spending is amounted to EUR 401 million). The Croatian Ministry of Economy (2017) states that the largest share of sales through the Internet is achieved in the category of "accommodation and preparation and serving of food" (48%). The ICT sector comprises the highest percentage of Internet sales, where 66% of companies acquire needed goods and services via online channels.

As far as the use of the Internet is concerned, 91% of Croatian citizens use the Internet to collect information on products and services, 91% for reading newspapers and magazines, 80% for watching video content like YouTube, 79% for using electronic mail, 73% for collecting health information, 69% for using social networks, etc. (Croatian Bureau of Statistics, 2016).

According to Babic et al. (2011), in 2010 the B2C segment in Croatia accounted for around 13% of total electronic commerce, while the remaining 87% is trading among companies (B2B) segment. In addition, according to data by the Croatian Ministry of Economic (2017), the average spending per e-customer within 6 months in Croatia is 227 EUR. The report of the Croatian Bureau of Statistics (2016) emphasizes the increase in online purchases. In 2016, this indicator reached 33% of the population. Respondents within the aforementioned study mostly bought clothing and sports equipment, (57% of respondents), household necessities (34%), tickets for events (31%), electronic equipment (29%), and computer components (25% of respondents).

E-Commerce Advantages

If we discuss advantages of e-commerce from the consumer perspective, Turban et al. (2010, p. 77) state the following advantages:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Ubiquity – possibility to shop anytime and anywhere
- More products and services – enlarged assortments (more retailers, more products more styles available)
- Customization of products and services
- Cheaper products and services – improved possibility of price comparison
- Instant delivery – digital products can be downloaded immediately upon payment
- Information availability – easy finding of needed product/service with exhaustive information available online
- Convenient auction participation
- Sometimes there are no taxes
- Possibility of telecommuting – possibility to study and work at home
- Electronic socialization – socialization in online communities at home
- Finding of unique products – using online auctions to search collectible products.

Laundon & Traver (2015, p. 375) claim that important drivers of online shopping are price, convenience (shopping from home), the ability to shop 24/7, increased variety of available products, improved comparability of products and offers, etc.

Some studies empirically test and explain consumer perception of e-commerce benefits. Dholakia & Uusitalo (2002) propose that online shopping and traditional shopping are clearly differentiated in terms of perceived shopping benefits. Nikolaeva (2006) proposes a model of e-commerce adoption by retailers that includes determinant factors in three areas: (1) perceived benefits, (2) organizational readiness and (3) external influences.

Bonera (2011) found that the perception of the usefulness and emotional commitment regarding online shopping platforms have to be added to the already mentioned utilitarian motives of e-commerce usage. Furthermore, perceived security of online shopping also plays an important role in decision making to shop or not to shop online. Pilik et al. (2017) suggest that the key driver for customers in the Czech Republic is the price of merchandize, while convenience is more important for consumers who prefer brick-and-mortar stores, and still shop online irregularly. Bong (2017) analyzed users of e-commerce and non-users of e-commerce and showed that they significantly differ in purchasing tendency, information channels used and attitudes on future online shopping orientation.

Strugar et al. (2011) explain perceptions of students regarding e-commerce advantages compared to traditional stores. They found that for students the most important advantage is the availability of goods and services that are not offered at a given market. Then comes easier comparability of prices and product characteristics, while the possibility to shop abroad without travel expenses is ranked as the third benefit of e-commerce.

Parker & Wang (2016) provide insight into m-commerce (as a newest form of e-commerce) within fashion retailing from the aspect of shopping m-application engagement. They claim that utilitarian motivators to shop online via m-applications are ranked in the following order of importance: efficiency, convenience, personalized service, convenient operation processes. Moreover, findings by Kovačević et al. (2017) indicate that increasing use of mobile services is bringing new challenges, including making digital content available everywhere, always, and in real time. This challenge is increasing in the context of social media as well (Roblek et al., 2013). Zhang et al. (2017) explored the impact of online reviews on consumer behavior and concluded that it is a new form of word-of-mouth marketing channel that is very effective for niche products and especially effective for experienced online consumers.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Individualization of consumer approach is one more benefit of e-commerce. The trend of individualization is observable when a consumer switches from mass products to fully personalized products. Large sports footwear producers such as Nike, Adidas and Reebok have recognized this trend and offered the possibility of product customization. By using digital platforms and applications, consumers can easily design their own, individualized sport shoes without a large difference in price compared to the serial product. This opportunity is added value in consumer-producer relations. For example, Nike offers this possibility via the NikeID web application, through which consumers can chose a generic sneaker model and customize colors, signs and other design features (see Nike web, 2017).

E-Commerce Obstacles

We have to emphasize some disadvantages of or obstacles to e-commerce both for companies and for consumers. Spremić (2004, p. 120) outlines following disadvantages and risks of e-commerce:

- Security of operation and running of business over the Internet is endangered
- Exposure to the risk of misusage
- Insufficient or inadequate technological infrastructure
- Underdeveloped software support
- Technically demanding transition from the existing mode of operation to electronic mode
- Costs of development and implementation of electronic business
- Privacy issues and copyright protection issues
- Lack of trust in virtual business environment
- Unavailability of experts and knowledge
- Insufficient and underdeveloped legal framework
- Other shortcomings and problems

Security and privacy are two factors related to customer trust and they are in direct connection with online threats and online frauds. Joines et al. (2003) discuss motivators for web use that directly influence the e-commerce activities of consumers and claims that transactional privacy concerns are negatively related to the percentage of time spent on product searches and online shopping. In addition, they isolated three groups of positive e-commerce motivators: information availability, interactivity and socialization. Chellappa and Pavlou (2002) and Suh & Han (2014) show a significant correlation between perceived information security and trust in e-commerce transactions. Kim et al. (2008) strongly claim that Internet consumers' trust has a strong impact on online purchasing decisions.

Smith (2004) is recommending companies to strive to apply the latest safety and privacy policies and technologies to ensure a carefree shopping experience to their customers, due to increasing cybercriminal activities, the concerns of consumers regarding privacy and increased security over time. This topic is addressed in Henari & Mahboob (2008) who emphasize the insecurity of consumers in regulation level and privacy issues when sharing information online.

Even though there are increasing investments in data protection and improved security, and despite the fact that legal framework is set up in the field of consumer protection in the digital environment, a significant number of consumers still feel concerned when sharing their credit card number or personal information online.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Many other factors, such as honesty and reliability, are explored in research studies as well (see Mandić, 2009). Strugar et al. (2011) based on primary research rank the main issues of e-commerce compared to classical stores. According to this study, the three mostly observed disadvantages are:

1. Complicated return policy
2. An absence of physical contact with products
3. Questionable trustworthiness of information in online stores

Šimičević et al. (2013) state that trust is a factor that is significantly more important to the adoption of e-commerce and it is related with perceived barriers to online purchasing, such as difficult information search, more expensive purchasing, long delivery times, problems of home delivery, concern about personal and credit card data, etc. In addition, Hamidi & Moradi (2017) suggest that on time and correct electronic seller's responses affect customer loyalty positively.

Petković et al. (2016) examined privacy and security issues in mobile phone commerce. According to this research, the five most disturbing issues and fears from the perspective of examinees are: (1) underdeveloped and not fully explained return policies, (2) too many advertising messages via smartphones, (3) too many unwanted requests within mobile applications (surveys, personal data etc.), (4) fear of personal information misusage, and (5) fear that the legal framework concerning privacy and consumer security protection is not developed enough.

Sinha & Singh (2017) claim that consumers' purchase intentions are determined by their attitude towards online purchases, based on both perceived benefits (hedonic benefit, convenience benefit, economic benefit and variety) and perceived risks (product risk and financial risk).

An Overview of the Age-Related Research on Consumer Behavior

There are numerous studies examining age-related differences and generation gaps among consumers for various groups of products and various sales channels, especially sales channels related to intensive technological usage.

Meneely et al. (2009) show how consumers change their retail behavior when getting older. Based on empirical findings they suggest that it is inevitable that retailers take into account age when differentiating consumer groups in order to adjust their business approach to the targeted market. In addition, Aron et al. (2007) found that older consumers are more critical when it comes towards retailers and they tend to discuss problems more often than younger consumers do, but that they are also telling more people their concerns about the retailing company and/or products bought. Age differences in retailing behavior were proven by Seok & Salus (2008) who explored how shopping behavior and store evaluation criteria differ among consumer age groups in apparel retailing. Rocha et al. (2005) discuss different requirements for clothing and fashion products based on age and gender, and support the influence of age on consumer behavior in apparel retailing. Litrell et al. (2005) give a detailed explanation of generation differences, claiming that consumers from the Baby Boomer and Swing generations pay more attention to comfort, value and quality of apparel together with greater preference towards authentic and local products than Generation X consumers do. In addition, Eastman & Liu (2012) focus on status consumption and suggest that variance in status consumption is most influenced by age or generation cohort of consumer among all demographic variables. Moreover, the results of Moschis et al. (2011) show that older consumers differ from younger consumers in the field of apparel and footwear and that there are certain differences

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

according to age within the mature consumer group. Price reductions and special sales are drivers of brand selection in the mature consumer group, while ease of returning products and frequency of items on sale are drivers of department store loyalty (see more details in Moschis et al., 2011).

Age-related differences are explored in the sportswear group of products as well. For instance, Rahulan et al. (2015) compared the Baby Boomer generation with generation Y in compression sportswear and came to the conclusion that consumers in Generation Y are more inquisitive and more focused on technical information, while consumers in the Baby Boomer Generation are more confident and quicker in making purchase decisions.

Technology implementation in relation to generational gaps is an emerging scientific topic. Even though the literature is scarce, we will mention several studies addressing this topic.

Harris et al. (2016) investigated attitudes towards new technologies in the banking sector. Their results suggest that older consumers perceive greater value in traditional banking and that, on the other hand, younger consumers are more open to the newest technologies. Dean (2008) showed that adoption of self-service technologies in retail stores and showed that the adoption rate is lower in the older consumer generation because they have less confidence in technology and they expressed greater concerns regarding missing human interaction especially when it comes to payment information sharing at checkout. Furthermore, Malik et al. (2016) proved that older age groups are less active in sharing photos online and they have a lower trust level in social networks as tools for information sharing. In both age groups, users expressed consciousness and concern about privacy, however, younger consumers in the study of Malik et al. (2016) showed greater usage of privacy-protection than older consumers did.

Sorce et al. (2005) empirically proved age-related differences among younger and older online shoppers exist for many product categories. Leppel & McCloskey (2011) compared three consumer age groups and came to the following conclusions: (1) consumers in older consumer groups have a greater concern about security, (2) consumers in older groups are more frustrated when searching for product information online, (3) consumers in the oldest group rarely make Internet purchases, but use the Internet as a source of product information. In addition, Leppel and McCloskey (2011) explored significant differences between consumer age groups regarding product categories. For instance, elderly shoppers use Internet to obtain information and to purchase medical supplies more often than younger shoppers do. The same finding is observed for food products.

Nalbantis et al. (2017) claim that purchase channel choice for sports merchandise is significantly affected by sociodemographic attributes such as gender, education, income, and place of residence. In addition, recent online shopping behavior in various countries (Pilik et al., 2017; Kuoppamaki et al., 2017) confirms that consumer online behavior depends on the age or generation of shopper. Moreover, the results in the aforementioned studies suggest that mobile-based online shopping is best predicted by age and as age grows shoppers pay more attention to the convenience of shopping.

Hovewer, there is a scarcity of research focusing on the particular product and consumer generation gap when implementing new technologies in retail channels. In this paper, due to the previously mentioned increase of the sports footwear market and the fact that e-commerce is being recognized as an important retail channel, we will empirically focus on e-commerce as a retail channel for this particular group of products. In the empirical research, we will focus on the perception of e-commerce benefits and risks. Moreover, as there is a lack of studies focusing on particular product groups within e-commerce, this primary research will fill the gap within existing literature in retailing, category management, e-commerce and sports management, while providing information on consumer perceptions about sports footwear both for professional and recreational usage. In addition, we will focus on the consumer generation gap

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

in order to prove that it can be observed within this product category as it was previously observed for medical supplies, food, apparel, etc.

In the paper, four hypotheses will be tested and they are set up and adjusted to the particular product group based upon the analyzed literature on the generation divide in e-commerce (Rahulan et al., 2015; Harris et al., 2016; Dean, 2008; Malik et al., 2016; Sorce et al., 2005; Leppel & McCloskey, 2011):

- **H1:** Younger consumers have a more positive attitude towards advantages of e-commerce application in sport footwear shopping.
- **H2:** Older consumers express a higher degree of concern towards obstacles of e-commerce application in sports footwear shopping.
- **H3:** Younger consumers use the Internet as a source of purchasing information when buying sports footwear more often than middle-aged consumers do.
- **H4:** Younger consumers express more positive attitudes towards future use of e-commerce in sports footwear purchasing than middle-aged consumers do.

THE EMPIRICAL RESEARCH RESULTS ON SPORT FOOTWEAR ONLINE SHOPPING

Research Methodology and Sample

The research was conducted during the first half of May, 2017, and included two age groups: the younger population (18-39 years old) and the middle-aged population (40-59 years old). There were 202 respondents to this study, of which 110 respondents were of the younger age group and 92 respondents were of the middle-aged population. Of the 110 respondents of the younger population, 66 were female (60%) and 44 were male (40%). In the middle-aged population there were 92 respondents, 49 of whom were female (53.3%) and 43 were male (46.7%).

The primary survey was conducted by using the survey questionnaire method and was carried out using Google Forms, by social network sharing, and by emailing and filling in a survey in print format in order to cover a relevant number of respondents in both age groups. The questions of the closed type of multiple choice were used, and questions in the form of the Likert scale where several statements were pointed out and respondents were required to express the degree of agreement or importance, with 1 indicated a total disagreement or irrelevance, while 5 indicated total agreement or importance of the examined claim.

The survey questionnaire included 17 questions, of which the first 5 questions related to socio-demographic features, followed by 4 questions related to sports activities and the frequency and location of purchasing of sports footwear. In addition, the following four questions explored the importance of some advantages, such as buying in traditional stores and via the Internet, then question obstacles to online shopping, and the general preferences and priorities when purchasing sports footwear. The last four questions were about the Internet as a new channel of consumer communication and new shopping channel.

In this paper, we will focus on the results obtained through questions related to the online purchase of sports footwear; questions designed based on the literature mentioned in the previous chapter. For demographic variables, we combined and adjusted questions from Chen et. al (2015) and Strugar et al. (2011). Part of the questionnaire on e-commerce benefits is designed according to Turban et al. (2010,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

p. 77), Laundon & Traver (2015, p. 375), Dholakia & Uusitalo (2002), Nikolaeva (2006), Bonera (2011), Strugar et al. (2011), Parker & Wang (2016). While part of the questionnaire regarding e-commerce obstacles and risks is designed according to Joines et al. (2003), Chellappa and Pavlou (2002), Panian (2002, p. 61), Suh & Han (2014), Strugar et al. (2011), Šimičević et al. (2013), Petković et al. (2016). The initial set of questions is further adjusted according to characteristics of the specific product category (sports footwear).

Firstly, Table 1 shows socio-demographic characteristics for each age group of respondents. Out of 110 members of the younger respondents, 66 (60%) are female and 44 (40%) are male. Given the level of education, 48 (43.6%) of the respondents have a high level of education (bachelor degree), and 36 (32.7%) have a high school qualification. While 14 (12.7%) have a higher level of professional education, 10 (9.1%) hold a masters degree, only 1 respondent (0.9%) has a doctorate, and only 1 (0.9%) respondent completed only elementary school. Furthermore, 35 (31.8%) of the respondents of the younger age group stated that they were studying and working occasionally. The number of those who are full-time employees and those who only studied and did not work at all, is the same, namely 29 (26.4%). Subsequently, 11 (10%) of respondents are studying and working, while 6 (5.5%) are unemployed.

Table 1. Socio-demographic characteristics of the sample

Characteristic	Relative frequencies younger respondents (N = 110)	Relative frequencies middle-aged respondents (N = 92)
GENDER		
Male	40%	46.7%
Female	60%	53.3%
EDUCATION LEVEL		
Elementary school	0.9%	1.1%
High school	32.7%	52.2%
Professional degree	12.7%	13%
Bachelor degree	43.6%	27.2%
Master degree	9.1%	6.5%
PhD	0.9%	0%
EMPLOYMENT		
Employed	26.4%	94.6%
Fully employed with student status	10%	0%
Student that works occasionally	31.8%	1.1%
Non-working student	26.4%	0%
Unemployed	5.5%	4.3%

Note: * 1 EUR = 7.5 HRK (Source: Own research)

Of the 92 middle-aged subjects, 49 (53.3%) are female and 43 (46.7%) were male. With regard to the level of education, 48 (52.2%) of respondents have a secondary education (high school), while 25 (27.2%) have a bachelor degree. There are 12 (13%) with higher professional education, 6 (6.5%), and 1 (1.1%) of respondents have completed only elementary school while no one holds a doctorate. 87 (94.6%) of the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

middle age group respondents declared themselves as employed, then 4 (4.3%) as unemployed, while 1 (1.1%) said that he/she studies and occasionally works. Table 2 shows the results for sporting activities and the purchase of their sports shoes for each age group within the sample.

Table 2. Intensity of sports activity and general purchasing habits in the field of sports footwear within the sample

	Younger consumers	Middle-aged consumers	Chi-square (p-value)
Intensity of sport activity			
Professional	0.90%	0.00%	88.152 (<0.001)
Semi-professional	63.60%	2.20%	
Recreational	7.30%	21.70%	
Inactive	28.20%	76.10%	
Frequency of footwear shopping			
Once a month	3.60%	0.00%	50.617 (< 0.001)
Several times a year	44.50%	5.40%	
Once a year	25.50%	28.30%	
Less than once a year	26.40%	66.30%	
Annual spending on own sport footwear			
Less than 500 HRK	52.70%	79.30%	20.013 (< 0.001)
500-1000 HRK	33.60%	19.60%	
More than 1000 HRK	13.70%	1.10%	

Note: 1 EUR = 7.5 HRK
Source: Own research

As shown in Table 2, out of 110 respondents belonging to the younger population, 70 (63.6%) are engaged in sports recreation, 31 (28.2%) do not deal with sports at all, 8 (7.3%) are engaged in sports semi-professionally, while only 1 person (0.9% sample) professionally deals with sports. Out of 92 respondents of the middle age population, 70 (76.1%) do not deal with sports at all, 20 (21.7%) are engaged in sports recreationally, 2 (2.2%) are engaged in sport semi-professionally, and no one is a professional athlete.

The largest proportion of younger respondents (44.5%), state that they buy sports footwear several times a year (see Table 2), which is logical as it is a younger population that generally has a higher affinity for frequent buying and changing existing clothing and shoes. Then, 26.4% buy sports footwear less than once a year, 25.5% buy once a year, while 3.6% of the respondents buy sports shoes on a monthly basis. On the other hand, middle-aged respondents mostly buy sports shoes less than once a year, 66.3% of them. Once per-year sports shoes are bought by 28.3%, while 5.4% buy them several times a year. It is obvious that this middle-aged group rarely buys sports footwear, partly because they are more concerned about it and probably are buying products of higher quality, and, therefore, they have a lower need for change due to endurance of the footwear. On the other hand, the reason could be their lower engagement in sports activities as shown in Table 2.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

It is evident that, at both age groups, most of the respondents spend up to 500 HRK per year on sports shoes (see Table 2), but in the middle-aged population, this is reflected in a considerably higher percentage. The main reason for this lies in one of the previous questions where it turned out that the number of sportsmen, whether recreational, semi-professional or professional, was considerably higher in the younger group than in the middle-aged group. As the chi-squared test indicates, described differences between observed consumer generation groups regarding the intensity of sports activity, frequency of footwear shopping and annual spending on sports footwear are statistically significant at $\alpha=0.05$ (all p-values are lower than α).

RESULTS AND DISCUSSION

Differences in Attitudes Towards E-Commerce Advantages

In Table 3 average grades and modal values regarding statements on e-commerce advantages are given for each consumer group. If e-commerce advantages are ranked according to average grades, the order of the most important advantages perceived by younger consumers is: (1) better choice of footwear than in physical stores (3.655), (2) easier and quicker collection of information about product (3.464), (3) possibility of buying at any time of day (3.436), (4) cheaper shopping than in stores (3.364) and (5) simplicity and speed of shopping (3.309). This finding slightly differs from previous research studies that isolate prices (Pilik er al, 2017) and price comparability (Strugar et. al, 2011) as the key e-commerce advantages. On the other hand, this supports Parker & Wang's (2016) findings on the importance of utilitarian motives when driving customers to online shopping.

If we turn to the middle-aged population, the difference in attitudes are obvious. We can conclude that all examined e-commerce advantages for purchasing sports footwear within this age group are irrelevant. The majority of middle-aged examinees express that each given statement on e-commerce advantage is completely irrelevant (in Table 3 see modal values for the middle-aged group).

Even though the difference between tested groups was obvious, we performed the chi-squared test and the Wilks' G2 test upon each statement. P-values of the performed test confirmed that attitudes towards e-commerce are dependent on the generation of the consumer (at significance level 0.05). Since all average grades and modal values are higher for younger consumers (see Table 3), we confirm the first hypothesis, i.e. we confirm that younger consumers have a more positive attitude towards the advantages of e-commerce application in sports footwear shopping.

Differences in Attitudes Regarding E-Commerce Obstacles

Table 4 outlines obstacles of e-commerce in the area of sports footwear purchasing. Both age groups show a relatively high level of awareness of the risks of e-commerce purchasing. In both consumer groups three main concerns regarding e-commerce of sports footwear are: (1) impossibility to try the product (younger consumers - average grade 4.273; middle-aged consumers – average grade 4.859), (2) complicated return process (young 3.882, middle-aged 4.848) and (3) fear of delivery of the wrong / damaged product (young 3.855, middle-aged 4.641). Those findings confirm previous studies by Strugar et al. (2017), Petkovic et al. (2011) and Sina & Singh (2017) who also discovered that perceived product risk is the main obstacle of e-commerce adoption and this risk is manifested in the absence of physical

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

touch, damaged or wrongly dispatched products and complicated return process when product is not meeting the customer's expectations.

Table 3. Advantages of e-commerce for sport footwear purchasing

E-commerce advantages	Younger consumers		Middle-aged consumers		Chi-squared (p-value) Cramer's V	Wilks'G2 (p-value)
	Average grade	Modal value	Average grade	Modal value		
simplicity and speed of purchase	3.309	4 – important (38.2%)	1.500	1 – completely irrelevant (59.8%)	105.978 (< 0.0001) 0.724	124.012 (< 0.0001)
saving time and money for transportation to the store	2.973	3 – neutral (30.9%)	1.478	1 – completely irrelevant (58.7%)	89.299 (< 0.0001) 0.665	105.149 (< 0.0001)
saving time spent in shopping	3.018	4 – important (33.6%)	1.478	1 – completely irrelevant (58.7%)	92.587 (< 0.0001) 0.677	109.203 (< 0.0001)
better choice than in classic stores	3.655	4 – important (49.1%)	1.500	1 – completely irrelevant (59.8%)	119.880 (< 0.0001) 0.770	144.058 (< 0.0001)
ability to customize shoes	3.036	3 – neutral (30.0%)	1.478	1 – completely irrelevant (58.7%)	89.587 (< 0.0001) 0.666	105.541 (< 0.0001)
cheaper than classic shops	3.364	4 – important (42.7%)	1.478	1 – completely irrelevant (58.7%)	119.174 (< 0.0001) 0.768	141.222 (< 0.0001)
24/7 shopping	3.436	4 – important (40.0%)	1.544	1 – completely irrelevant (58.7%)	108.637 (< 0.0001) 0.733	124.111 (< 0.0001)
easier and quicker collection of information about product	3.464	4 – important (40.9%)	1.544	1 – completely irrelevant (58.7%)	114.300 (< 0.0001) 0.752	131.116 (< 0.0001)

Note: Likert 5 scale was used (1 – completely irrelevant, 5- completely relevant) (Source: Own research)

From Table 4, it is obvious that for each given statement, middle-aged consumers express a higher level of agreement, but the relevance of this difference between populations is not as obvious as it was for statements on e-commerce advantages. Therefore, for each statement, the chi-test p-value is calculated and in Table 4 we can see that the p-value is lower than 0.05, therefore we conclude that the difference in attitudes between generation groups is statistically significant at level 0.05. Therefore, we can accept the second hypothesis that older consumers express higher degree of concern towards the obstacles of e-commerce application in sports footwear shopping.

Chellappa and Pavlou (2002), Leppel & McCloskey (2011) and Suh & Han (2014) point out that there is a correlation between perceived information security and trust in e-commerce transactions, which, furthermore, has a strong impact on online purchasing decisions (Kim et al., 2008; Mandić, 2009, Šimičević et al. 2013). Therefore, based on our findings we can expect that the older population (which expresses more concern regarding e-commerce risks) is going to spend less money online and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

utilize e-commerce as a purchasing source at a lower level than the younger population. However, this claim has to be tested in detail in future research.

Differences Regarding ROBO Principle, Future E-Commerce Usage and the Possibility of Sport Footwear Customization

For modern shoppers, the Internet is a significant source of information prior to purchasing. Therefore, in the following question we wanted to examine the occurrence of the ROBO (research online, buy offline) or ROPO (research online, purchase offline) principle in both consumer groups. In Figure 1 relative frequencies are shown for both consumer groups.

Table 4. Obstacles of e-commerce for sport footwear purchasing

E-commerce obstacles	Younger consumers		Middle-aged consumers		Chi-squared (p-value) Cramer's V	Wilks'G2 (p-value)
	Average grade	Modal value	Average grade	Modal value		
fear of fraud	3.518	4 – relevant (34.5%)	3.935	4 – relevant (52.2%)	16.362 (= 0.0026) 0.724	17.805 (= 0.0013)

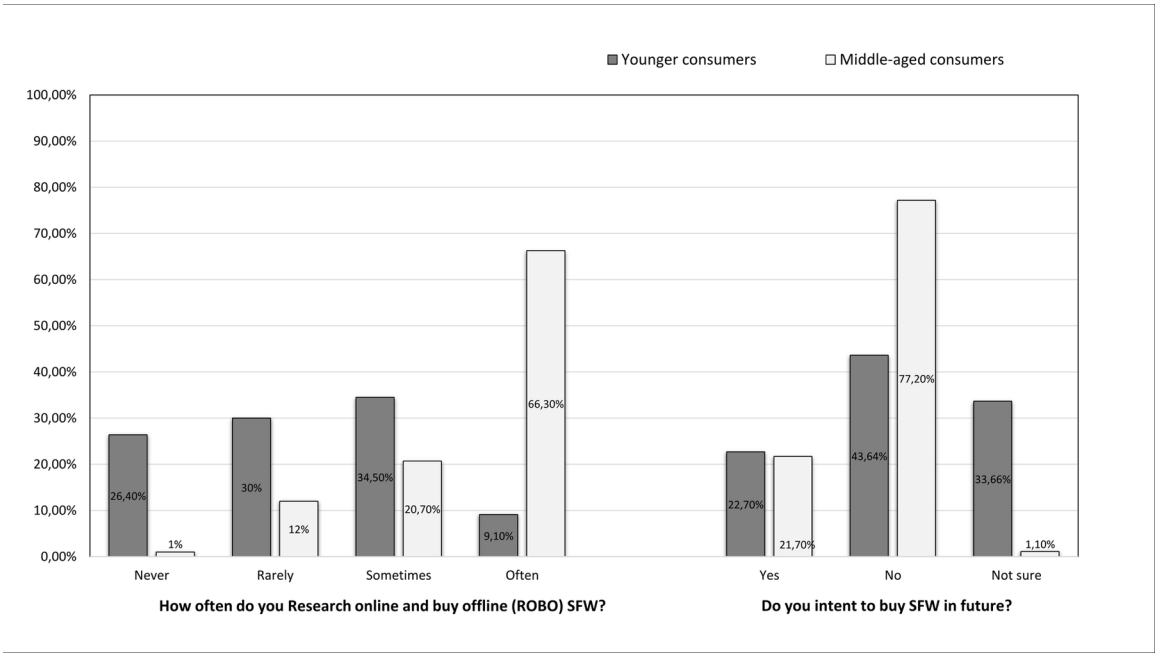
When it comes to gathering information about sports footwear online before purchasing in traditional stores, 34.5% of younger respondents reported that they behave in this way rarely. 30% do ROBO occasionally, 26.4% often collect information on the Internet, while those who never research online prior to purchasing sports footwear are in the minority (only 9.1%). In the middle-aged group, 2/3 of respondents never collect information about sports footwear on the Internet before purchasing in stores (66.3%), 20.7% do it rarely, 12% occasionally, and only 1.1% often do research online before buying sports footwear in a classical store (see ROBO columns at Figure 1).

Figure 1. Research online and buying offline (ROBO) and future intention to buy online for sport footwear (SFW) (Source: Own research)



Based on everything aforementioned we can accept the third hypothesis, which states that younger consumers use the Internet as a source of purchasing information when buying sports footwear more often than middle-aged consumers do.

In addition, we asked both consumer groups about their future intention to use e-commerce as a channel for sports footwear purchasing. The uncertainty regarding the purchase of sports footwear over the Internet in the future was shown by 43.6% respondents of the younger population, 33.6% of them believe that they will buy sports footwear online in the future, while 27.7% of respondents believe that they will never purchase this type of products online (see Figure 1). On the other hand, in the middle-aged group, a majority of respondents do not intend to buy sports shoes online in the future (77.2%), 21.7% claims that they are not sure about that, while only 1.1% expressed the intention to buy sports footwear online.

Moreover, as was discussed in the previous chapter, some producers are giving consumers the opportunity to create their own sports shoes online. In our research in two final questions, we asked respondents about their awareness of this possibility and their intention to use this possibility in the future. In Table

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

5 relative frequencies are shown regarding these two questions. The younger population express a high level of awareness about the possibility of sports footwear customization online (65.5% respondents stated that they have heard of this possibility), while in the middle-aged group there is a majority that are not aware of this possibility (81.50%). A majority of young consumers have no experience, but plan to use this possibility in the future (52.70%), but even in this population the proportion of those who do not plan to use this possibility is rather high (44.5%). On the other hand, in the group of middle-aged consumers 96.7% respondents have no experience and do no plan to use this option in the future.

Table 5. Customization and online self-design of sport footwear

	Younger consumers	**Middle-aged consumers**
Awareness		
Yes	65.50%	18.50%
No	34.50%	81.50%
Use and future intention to use		
Some experience	2.80%	0.00%
No experience, but I plan to use this option in the future	52.70%	3.30%
No experience, not planning to use it in the future	44.50%	96.70%

(Source: Own research)

Based on everything aforementioned and the data presented in Figure 1 and Table 5, we confirm the fourth hypothesis that younger consumers express more positive attitudes towards future use of e-commerce in sports footwear purchasing than middle-aged consumers do. This finding supports our previously stated prediction that higher concern of the older population towards e-commerce risk can reflect their future utilization of e-commerce. Furthermore, this is in line with finding of Bong (2017) who claims that experienced e-commerce users (in our case, the younger population) differs in purchasing tendency to unexperienced e-commerce users (in our case, the older population).

Moreover, findings on age-related differences reflect broad knowledge gathered in previous studies (Dholakia and Uusitalo, 2002 and Joines et al., 2003; Sorce et al., 2005; Leppel & McCloskey, 2011; Nalbantis et al., 2017 Pilik et al., 2017, Kuoppamaki et al., 2017;) by focusing on a specific type of products, i.e. sports footwear. This product category was not investigated in previous research studies, so the presented findings are a unique contribution to understanding age-related issues in specialized retailing via online channels.

CONCLUSION

The sports footwear market shows growing trends both in traditional and in digital sales channels. In this paper, we focused on electronic commerce of sports footwear as a particular product category. Based on the critical literature review, we especially examined the generation gap in perception of benefits and risks of electronic commerce of sports footwear. Based on the research conducted on two age groups, younger consumers (aged 18-39) and middle-aged consumers (40-59 years old), we empirically proved

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

all research hypotheses and conclude that younger consumers have more a positive attitude towards advantages of e-commerce application in sports footwear shopping. In addition, older consumers express a higher degree of concern towards obstacles of e-commerce application in sports footwear shopping. Moreover, younger consumers use the Internet as a source of purchasing information when buying sports footwear more often than middle-aged consumers do. Finally, younger consumers express more positive attitudes towards future use of e-commerce in sports footwear purchasing than middle-aged consumers do.

Information gathering about sports footwear over the Internet before shopping occurs much more frequently among younger people, as well as the intention to buy sports footwear online over the Internet. According to the research, the majority of young people knew about the possibility of customization of sports shoes, while almost half of them state that they intend to use this possibility in the future. In the middle-aged consumer group there is a rather small proportion of those who have heard about the option of sports shoes customization.

The contributions of our study are multiple. As stated previously, there are many studies on general e-commerce and studies confirming existing age differences in consumer behavior, but there is a notable scarcity of studies examining age-differences in consumer behavior in electronic commerce. Moreover, there are research studies that emphasize changing consumer behavior regarding the type of products being purchased both in classical and in online channels. However, there is no study explaining the challenges, benefits and obstacles of e-commerce of sports footwear as a specific product group. These findings are a valuable empirical contribution both to understanding what are perceived advantages and what are the main fears observed by consumers when dealing with sports footwear. In addition, these findings empirically confirm that there is an existing generation gap that has to be taken into account when planning the strategy of e-commerce usage for this particular product group. It gives insight into what elements a certain company has to pay attention to when targeting a certain consumer generation.

The main limitations of this study are (1) a rather small sample and (2) the narrow geographical area of the survey conducted. Therefore, in the near future the research should be conducted on a larger number of examinees and in a wider geographic area. In addition, we did not analyze attitudes by gender nor by sports footwear purpose. Future studies could explore differences among males and females, but also differences among those who use sports footwear professionally or those who use it only for recreational purposes.

Chapter 62
Consumer Shopping Orientations and Online Purchases of Rural Tourism Services

Aleksandar Grubor
Faculty of Economics, University of Novi Sad, Serbia

Nenad Djokic
Faculty of Economics, University of Novi Sad, Serbia

ABSTRACT

The main goal of the chapter is to find out which consumer shopping orientations can be brought in connection to purchases of the services of rural tourism in online channel. Besides theoretical framework concerning rural tourism services and their relation to sustainable development of rural areas, as well as factors of online purchases, the chapter presents the results of primary research. The research is part of wider research conducted concerning online shopping behavior in Serbia. A total of 300 respondents participated. Convenience sampling was implemented. The results confirm that online sale of rural tourism services can be explained when considering consumer shopping orientations and that these orientations can be connected to demographic characteristics of consumers. Finally, managerial implications are considered.

INTRODUCTION

There can be identified a positive connection between development of rural tourism and sustainable development of rural areas. These consequences can be identified concerning all, economic, social and ecological issues. In order to promote future development of rural tourism services, it is needed to understand their consumers and be able to communicate the value to them appropriately.

An opportunity for communication the value of rural tourism services as well as for completing the sale process concerning them is present in online channel. The number of different factors determines the success of this channel. A classification of them can be found in the literature (e.g. Chang, Cheung, & Lai, 2005) and characteristics of a supply and internet as a sale channel, consumer opinion concerning such purchases as well as their personal characteristics can be distinguished. Consumer shopping orientations can be listed among their personal characteristics.

Having all previously listed in mind, there are several objectives of this research:

Objective One: To define theoretical framework connecting rural tourism services, sustainable development, online purchases of those services and consumer shopping orientations.
Objective Two: To explore whether there can be identified the same consumer shopping orientations (recreational, experiential, convenience and economic) in research in Serbia as in research abroad.
Objective Three: To define the nature of correlation of each of consumer shopping orientation and online purchasing of rural tourism services.
Objective Four: To explore whether, which and to which extent consumer demographic characteristics influence the level of their shopping orientations.
Objective Five: To provide adequate managerial recommendations for providers of rural tourism services.

The knowledge regarding the topics can be used for increase of sale of services of rural tourism in domestic context of the authors (Republic of Serbia).

LITERATURE REVIEW

Sustainable development presents a widely discussed concept and can be explained in the modern conditions together with "environmental science" and "circular economy" as being important in finding solutions for a better environment (Sauvé, Bernard & Sloan, 2016). Hereby, the authors start from definition of sustainable development as: "meeting the needs of the present without compromising the ability of future generations to meet their own need" (p. 2) and stress ecological, social and economic goals within it.

When it comes to rural tourism, Lane and Kastenholz (2015) identify its evolution from sightseeing to a number of experiential activities. Rasoolimanesh et al. (2016) suggest that although tourism in general influences host communities economically, socially, and environmentally, there are differences between urban and rural tourism. Lane and Kastenholz (2015) also stress that a number of topics emerge regarding rural tourism (governance, leadership, networking, product development and marketing) and suggest creation of New Generation Rural Tourism, based on recent developments in management and marketing.

Trukhachev (2015) identifies several potential contributions of rural tourism to sustainable development of rural areas (p. 3055):

- "establishment of new employment opportunities and alternative sources of income for rural people;
- retention of economically active population and young people in rural areas, lower migration outflows;

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- establishment of a market for local agricultural and organic products, local specialties and products of folk crafts;
- preservation of the natural, environmental and cultural heritage of rural areas."

Gezici and Salihoğlu (2016) stress that unlike mass tourism, which can have negative impact regarding sustainability, rural tourism belongs to touristic activities with potential opposite effects. Muresan et al. (2016) suggest that local communities notice the beneficial influences of rural tourism for sustainable development of rural areas and understand it as "opportunity to enhance the wellbeing of the community in general, and particularly their own" acting in a manner that "the greater the perceived economical, socio-cultural and infrastructure benefits, the higher the support is from the local community in building future tourism strategies" (p. 11).

In conditions of online channel existing as a tool for communication of the value of rural tourism services and completing the sale process concerning them, the research of factors affecting such purchases becomes increasingly important. As already stated, consumers' characteristics can be identified among several groups of such factors, and consumer shopping orientations are listed within them. (Chang et al., 2005). These authors also list previous researches dealing with the topic (Donthu & Garcia, 1999; Li, Kuo & Russell, 1999; Swaminathan, Lepkowska-White & Rao, 1999).

Donthu and Garcia (1999) researched the profile of respondents purchasing on Internet by using a telephone survey. Besides shopping orientations, authors consider demographic characteristics of these respondents as well. Hereby, they conclude that people purchasing on Internet are oriented to convenience, innovativeness, impulsiveness and seeking variety. They are not connected largely to the brands and prices and have lower aversion to risk. Furthermore, they are older and wealthier.

Swaminathan et al. (1999) conclude that when it comes to shopping orientations, consumers who express the need for social interaction (mostly women) buy less frequently on Internet and spend less money in such transactions, while consumers who are oriented to convenience (usually men, better educated people, wealthier people) behave in the opposite manner.

Finally, Li et al. (1999) explore four different consumer shopping orientations - recreational, experiential, convenience and economic – and their influence in becoming Internet shopper and distinguishing frequent and less frequent Internet shoppers. They supposed that convenience orientation is in favor of Internet shopping, that experiential orientation has opposite influence, while remaining two shopping orientations are neutral. The results mostly support these assumptions, except the difference of presence of the convenience orientation at occasional Web buyers and non-Web buyers.

Having all previously listed in mind, following hypotheses are set:

Hypothesis One: There can be identified the same consumer shopping orientations (recreational, experiential, convenience and economic) in research in Serbia as in the research abroad.

Hypothesis Two: Recreational shopping orientation is not correlated to online purchasing of rural tourism services.

Hypothesis Three: Experiential shopping orientation is correlated to online purchasing of rural tourism services negatively.

Hypothesis Four: Convenience shopping orientation is correlated to online purchasing of rural tourism services positively.

Hypothesis Five: Economic shopping orientation is not correlated to online purchasing of rural tourism services.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis Six: Consumer demographic characteristics influence the level of their recreational shopping orientation significantly.

Hypothesis Seven: Consumer demographic characteristics influence the level of their experiential shopping orientation significantly.

Hypothesis Eight: Consumer demographic characteristics influence the level of their convenience shopping orientation significantly.

Hypothesis Nine: Consumer demographic characteristics influence the level of their economic shopping orientation significantly.

Testing of these hypotheses is presented in the following parts of the manuscript.

METHODOLOGY

This section of the manuscript provides information considering methodological foundations of primary research.

Instrument

The questionnaire consists of several parts. Its first part is related to respondents' gender, age, education, marital status, and perceived living standard. The second part of the questionnaire refers to consumer shopping orientations. This part of the questionnaire is taken from Li et al. (1999). The items were rated on five-point Likert scale from „strongly disagree" to "strongly agree". For the translation into Serbian language, back-translation procedure was used. The final, third part of the questionnaire was in relation to customer online purchases of rural tourism services. Hereby, the number of such purchases in the last 12 months was measured. It should be mentioned that the questionnaire was used not only by the authors, but also by several researches from their institution within the broader research of online shopping in Serbia.

Respondents

For the purpose of data processing, conducted in 2018, the convenience sample of 300 respondents was interviewed. The precondition to become a respondent was that a person has booked and/or bought rural tourism service online at least once during previous 12 months. Structured interviews by personal communication were used. It was needed about 10 minutes to fill in the part of the questionnaire concerning research presented within this manuscript.

The sample consists of 53.7% of male and 46.3% of female, as well as of 36% of married and 64% of single people. Furthermore, 64.3% of respondents were younger than the average age within the sample (more than 27 years), 63.3% had less years of education than the average number of those years was (14.3), and 46.3% marked living standard lower than the average (3.63 on five-point Likert scale). As it can be seen, the younger people are dominant within the sample. However, that can be justified in the context of the previously stated precondition to be included in the sample.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Procedures

The first part of the procedures is related to testing the questionnaire. The reliability and validity of the implemented scales were tested. Cronbach's alpha, Cronbach's alpha if item deleted, and Corrected item-total correlation were examined - separately for each of the researched consumer shopping orientations. Furthermore, Exploratory factor analysis by Maximum likelihood factor analysis method and Varimax rotation method was implemented on all the items of the scales for four factor solution. Before Exploratory factor analysis, adequacy of conducting it was tested by Kaiser-Meyer-Olkin (KMO) test and Bartlett's Test of Sphericity.

The second part of the procedures is related to bringing into relation each of the consumer shopping orientations and rural tourism services online purchases. Hereby, each of the shopping orientations was presented by means of ratings of all the respondents. As already stated, rural tourism services online purchases were presented by number of such purchases in the last 12 months. For testing whether there were statistically significant relations between them, Spearman rank correlation coefficient was used.

The third part of the procedures regarding the influence of demographic characteristics of respondents (gender, age, education, marital status, perceived living standard) on each of consumer shopping orientations was analysed by multiple regression with General Linear Model. The dependent variables - consumer shopping orientations (recreational, experiential, convenience and economic) were presented by means of ratings of all respondents. Coding was performed in a manner that the value of 0 was assigned to the following levels of demographic characteristics: male, younger than the average respondent, less educated than the average respondent, married, perceiving own living standard worse than the average respondent.

RESULTS

The results are divided into three sections. Firstly, testing of the questionnaire is presented. After that, the results of testing correlations between consumer shopping orientations and rural tourism services online purchases is shown. Finally, the results of General Linear Model regarding the influence of demographic characteristics of respondents on each of consumer shopping orientations is provided.

Testing the Instrument

Table 1 presents the results of reliability analysis.

The results show that the values of Cronbach's alpha for each of the consumer shopping orientations (recreational, experiential, convenience and economic) were higher than 0.7 as suggested by Nunnally (1978).

Furthermore, there were no items whose removal could increase the value of Cronbach's alpha. Finally, the values of Corrected item-total correlation were higher than threshold of 0.3 (Nunnally & Bernstein, 1994).

The result of Kaiser-Meyer-Olkin test of 0.782 higher than 0.6 (Kaiser, 1970, 1974) and the level of significance of the Barthlett's sphericity test of 0.000, suggested that it is adequate to perform exploratory factor analysis. Its results are shown in Table 2.

Four factors explained 53.466% of the total variance.

When observing Rotated factor matrix, it can be seen that all the loadings on appropriate factor were higher than 0.35 (minimum recommended for a sample of 250 respondents) (Hair et al., 1998) and that when comparing different factor loadings of each item, there were no unacceptable cross-loadings (higher than 0.2) (Matsunaga, 2010).

Consumer Shopping Orientations and Rural Tourism Services Online Purchases

The average assessments for consumer shopping orientations: recreational, experiential, convenience and economic are 2.95; 3.58; 4.14 and 3.94, respectively. The average number of online purchases of rural tourism services by the respondents in the last 12 months was 2.34.

When it comes to correlation analysis, it can be concluded that there is weak, negative and statistically significant correlation between recreational shopping orientation and number of online purchases of rural tourism services by the respondents in the last 12 months: $\rho = -0.118$, $n=300$, $p=0.041<0.05$. The correlation of such purchases is also weak, negative and statistically significant with experiential shopping orientation: $\rho = -0.197$, $n=300$, $p=0.001<0.05$.

However, when it comes to correlation of convenience shopping orientation and number of online purchases of rural tourism services by the respondents in the last 12 months, it is positive and statistically significant, although weak: $\rho = 0.207$, $n=300$, $p=0.000<0.05$.

Finally, there is no correlation between economic shopping orientation and number of online purchases of rural tourism services: $\rho = 0.067$, $n=300$, $p=0.248>0.05$.

General Linear Model

The results for the dependent variable Recreational consumer shopping orientation can be presented by a regression:

RCSO = 2.903 + 0.721*gender - 0.319*age - 0.140*education - 0.161*marital status - 0.039*living standard

Table 3 shows the values of those parameters as well as their significance.

Table 3. General linear model – dependent variable recreational consumer shopping orientation

Parameter	B	Std. Error	t	Sig.	95% Confidence Interval	
					Lower Bound	Upper Bound
Intercept	2.903	0.224	12.942	0.000	2.462	3.345
Gender	0.721	0.113	6.398	0.000	0.499	0.942

Out of the demographic characteristic of respondents, only gender and age affect statistically significantly the dependent variable. Hereby, in the units of five-point Likert scale, women are more recreationally oriented in shopping (0.721 of those units), as well as younger respondents (for 0.319 units). Other variables do not have significant influence, but it can be stated that less educated, married and respondents perceiving living standard worse than the average respondent are more oriented to recreational shopping. Table 4 presents values of dependent variable at different combinations of levels of independent variable.

Table 4. Demographic characteristics and recreational consumer shopping orientation (RCSO)

Gender	Age	Education	Marital Status	Perceived Living Standard	RCSO
male	younger than the average	less than the average	married	worse than the average	2.903
female	younger than the average	less than the average	married	worse than the average	3.624
male	older than the average	less than the average	married	worse than the average	2.584

The results for the dependent variable Experiential consumer shopping orientation are presented by a regression:

ECSO = 3.291 + 0.544*gender + 0.006*age - 0.258*education + 0.064*marital status + 0.173*living standard

Table 5 shows the values of those parameters and their significance.

Table 5. General linear model – dependent variable experiential consumer shopping orientation

Parameter	B	Std. Error	t	Sig.	95% Confidence Interval	
					Lower Bound	Upper Bound
Intercept	3.291	0.177	18.644	0.000	2.944	3.638
Gender	0.544	0.089	6.136	0.000	0.369	0.718
Age	0.006	0.114	0.051	0.959	-0.219	0.231
Education	-0.258	0.123	-2.092	0.037	-0.501	-0.015
Marital status	0.064	0.145	0.445	0.657	-0.221	0.350
Perceived living standard	0.173	0.087	1.976	0.049	0.001	0.344

Source: (Authors)

Out of the demographic characteristic of respondents, gender end education affect statistically significantly the dependent variable. In the units of five-point Likert scale, women are more experientially oriented in shopping (0.544 of those units) and respondents less educated than the average consumer (for 0.258 units). Other variables do not have significant influence, but it can be stated that older than the average respondent, single and respondents perceiving living standard better than the average respondent are more oriented to experiential shopping.

Table 6 presents values of dependent variable at different combinations of levels of independent variable.

The results for the dependent variable Convenience consumer shopping orientation can be presented by a regression:

CCSO = 4.226 + 0.084*gender + 0.052*age - 0.179*education - 0.272*marital status + 0.183*living standard

Table 7 shows the values of those parameters as well as their significance. Out of the demographic characteristic of respondents, living standard and marital status affect statistically significantly the dependent variable, at the level 0.05 and 0.10, respectively. Hereby, in the units of five-point Likert scale, as standard rises, also rises the orientation to convenience shopping (0.183 of those units). Furthermore, married people are also more convenience oriented in shopping (for 0.272 units). Other variables do not have significant influence, but it can be stated that women, older than the average respondent and more educated people are more in favour to convenience shopping. Table 8 presents values of dependent variable at different combinations of levels of independent variable.

The results for the dependent variable Economic consumer shopping orientation can be presented by a regression:

EcCSO = 3.811 + 0.276*gender + 0.016*age + 0.056*education + 0.016*marital status - 0.070*living standard

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Demographic characteristics and experiential consumer shopping orientation (ECSO)

Gender	Age	Education	Marital Status	Perceived Living Standard	ECSO
male	younger than the average	less than the average	married	worse than the average	3.291
female	younger than the average	less than the average	married	worse than the average	3.835
male	older than the average	less than the average	married	worse than the average	3.297
male	younger than the average	more than the average	married	worse than the average	3.033
male	younger than the average	less than the average	single	worse than the average	3.355
male	younger than the average	less than the average	married	better than the average	3.464
female	older than the average	less than the average	married	worse than the average	3.841
female	younger than the average	more than the average	married	worse than the average	3.577
female	younger than the average	less than the average	single	worse than the average	3.899
female	younger than the average	less than the average	married	better than the average	4.008

female	older than the average	more than the average	single	better than the average	3.820

Source: (Authors)

Table 9 shows the values of those parameters as well as their significance.

Out of the demographic characteristic of respondents, only gender affects statistically significantly the dependent variable. Hereby, in the units of five-point Likert scale, women are more economically oriented in shopping (0.276 of those units). Other variables do not have significant influence, but it can be concluded that older than the average respondent, more educated, single and respondents perceiving living standard worse than the average respondent are more oriented to economic shopping. Table 10 presents values of dependent variable at different combinations of levels of independent variable.

Following sections deals with the interpretation of the results.

DISCUSSION AND IMPLICATIONS

The results of the research confirm the first hypothesis i.e. that there can be identified the same consumer shopping orientations (recreational, experiential, convenience and economic) in research in Serbia as in the research abroad. Furthermore, it can be seen that the most expressed is convenience shopping orientation (mean assessment 4.14 on five-point Likert scale), followed by economic (3.94), experiential (3.58) and recreational (2.95). These results should be considered in the context of the precondition for a person to be included in the sample. Although not representative for the complete domestic market, it can be concluded that convenience is the most important aspect of shopping, at least for respondents who purchased rural tourism online services during previous 12 months period.

As for the hypotheses 2 to 5, it can be stated that when it comes to positive correlation of convenience shopping orientation to online purchasing of rural tourism services, negative correlation of experiential shopping orientation and number of such purchases, as well as no correlation of economic shopping orientation and online purchases, hypotheses are confirmed. This is also in accordance to some previous researches (Li et al., 1999). However, the negative correlation of recreational shopping orientation and online purchasing of rural tourism services was not hypothesized.

Generally, it can be concluded that, at domestic market, people who favor convenience in their shopping process are also positive towards online purchases of the researched services. This correlation is weak, but it might be stronger if the sample included those who do not buy online and their relation to convenience. Furthermore, online shopping can not fulfill the need to enjoy in shopping and to have direct experience. Because of the specifics of the rural tourism service, it might be that consumers prefer to visit certain area, compare different service providers, have direct experience and then make a decision.

Demographic characteristics influence the level of each of the four shopping orientations. This significant influence is present when it comes to gender and age in the case of recreational orientation, gender and education in the context of experiential orientation, marital status and perceived living standard in relation to convenience orientation and gender and economic orientation.

For the purpose of this research is especially important to observe demographic influences on convenience orientation, which is positively related to online tourism services purchases. Married people and those with better living standard are more oriented in that manner. It might be that obligations regarding family (especially young children) and work (which might translate into living standard) determine such respondents' preferences.

Previously listed results are partially in accordance to some of the researches abroad. In those researches, there is also positive relation of higher income and accepting internet shopping (Donthu & Garcia, 1999; Li, Kuo & Russell, 1999; Swaminathan, Lepkowska-White & Rao, 1999). However, the influence of gender, age and education from some of these researches is not identified in domestic conditions.

The results can have managerial implications for rural tourism service providers. Having in mind the possibilities of digital marketing and the profile of convenience shopping oriented consumers, there is possibility to target them more precisely. The information about marital status is mostly available, while the level of personal standard can be examined by, for example, identifying type of mobile phone by which person logs in to social networks. Furthermore, data about different interest and behaviors are also available in a large extent. By more precisely defining target group and look-a-like audience, service providers could be more successful in communication value. The appeal to convenience can be not only used, but also demonstrated in the process of booking and/or buying rural tourism service.

There is also a space to try to diminish negative correlations of the two shopping orientations (recreational and even experiential) with online purchases of rural tourism services. There should be tried to make the process of online selling more attractive and to implement recreational elements within it, so that it provides the same satisfaction as when not purchasing online. The dynamic development of IT technologies can be used in favor for such an attempt. Furthermore, although the experiential orientation relies on personal experience, if rural tourism services providers offer testimonials of their other guests as well as virtual visit to the place, there is also a possibility to try to address customers oriented in such manner.

FUTURE RESEARCH DIRECTIONS

The future researches can include broader range of determinants of rural tourism online purchases. Furthermore, respondents who do not perform such purchases can be included in the sample. There is also a possibility to try to compare the results from different countries. Wider approach to dependent variable measurement is also a possibility. Hereby, certain segmentation of supply side of tourism market is possible. It could also be useful to compare the views of service providers and service customers. Finally, dynamic approach and comparison of the results from different years would be beneficial.

CONCLUSION

The research presented within this manuscript firstly aimed to define theoretical framework connecting rural tourism services, sustainable development, online purchases of those services and consumer shopping orientations. Based on the secondary research, the framework consisting of those elements is established. Sustainable development, which is of the importance for current and future generations, can be established in rural areas by, among others, developing rural tourism. For the development of such tourism, it is necessary to research what is the value for consumers, as well as to create, deliver and communicate it. Online channel is an opportunity within that process, but its adequate usage is based on understanding what drives consumers toward online purchases. Hereby, among other factors, their shopping orientations are identified.

The primary research is also conducted in regard to previously listed topics. It aimed, as already stated, to identify whether there can be identified the same consumer shopping orientations (recreational, experiential, convenience and economic) in research in Serbia as in research abroad. The authors found evidence for such expectation. Furthermore, the goal was to define the nature of correlation of each of consumer shopping orientation and online purchasing of rural tourism services. Those relations are identified – positive in case of convenience, negative in case of recreational and experiential orientations. Finally, the research dealt with the question whether, which and to which extent consumer demographic characteristics influence the level of their shopping orientations. Each of the shopping orientations was influenced significantly by some of respondents' demographic characteristics. In the case of convenience orientation (which was of the special importance for this research because of its positive relation to rural tourism services online purchases), it was identified that married and people with better living standard are more in favor of this orientation.

Within the paper are also listed managerial recommendations for providers of rural tourism services. Besides, since similar researches are relatively rare in domestic conditions, this paper might be one of the steps of attracting wider scientific attention to the researched issue.

ACKNOWLEDGMENT

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

KEY TERMS AND DEFINITIONS

Consumer Shopping Orientations: Part of consumer lifestyle related to shopping.

Convenience Consumer Shopping Orientation: Part of consumer lifestyle related to shopping characterized by personal convenience in the shopping process.

Economic Consumer Shopping Orientation: Part of consumer lifestyle related to shopping characterized by trying to make the optimal decision in the shopping process.

Experiential Consumer Shopping Orientation: Part of consumer lifestyle related to shopping characterized by preferring direct experience in the shopping process.

Market Segmentation: Identifying groups of similar customers at the market for facilitating adequately approaching them.

Recreational Consumer Shopping Orientation: Part of consumer lifestyle related to shopping characterized by enjoyment in shopping activities.

Rural Tourism: A number of touristic activities referring to rural areas and providing their sustainable development.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sustainable Development: The concept referring to environment protection and containing economic, social and ecological aspects, which tries to make a balance between the needs and actions of current and future generations, in a sense that current generations do not jeopardize future ones.

Tourism Services Online Sale: A possibility to book and/or buy touristic service from rural tourism services providers by Internet.

Chapter 63
Enhancing Calculative Commitment and Customer Loyalty Through Online Relationship Marketing:
The Mediating Role of Online Trust

Sheena Lovia Boateng

Business School, University of Ghana, Ghana

ABSTRACT

This study examines the mediating role of online trust in enhancing calculative commitment and customer loyalty through online relationship marketing activities (engagement and interactivity). The study draws on signaling theory. Data were gathered from 429 retail bank customers in Ghana and analyzed using confirmatory factor analysis and structural path modelling. Findings suggest that engagement is assessed to be low by Ghanaian bank customers and presently has no influence on customer commitment, online trust, and customer loyalty. However, signals communicated through interactivity online is of great benefit to the banks in influencing customers' online trust, as well as their calculative commitment and loyalty. Further, though, website and email emerged as the most predominant technologies used in online relationship marketing (ORM), customers also expect banks to engage with them through social media, which has the potential to improve upon the current levels of ORM activities.

INTRODUCTION

Information Technology has been proffered in existing research to play a critical role when it comes to advancing the practice of Relationship Marketing (RM) within firms (Mishra & Li, 2008; Howcroft, Durkin, Armstrong & Emerson, 2007; Shapiro, Romano & Mittal, 2004). This phenomenon is evident in developed economies as well as developing economies (Boateng & Narteh, 2016; Verma, Sharma &

Sheth, 2016; Guo, 2014). In a developing economy like Ghana for example, all the 33 commercial banks operating in the country have officially launched some form of presence on the internet, either through a website or at least one of the numerous social media platforms to engage with their customers. There is also evidence to attest that in the banking industry, the internet elevates customer experience in both business and retail banking and enables individual banks to differentiate themselves in their competitive space (Deloitte, 2014). In view of this, industry practitioners are constantly enquiring as to how best they can further leverage new and emerging information technologies to facilitate their relationship development efforts with customers.

RM is an organizational process that involves the creation and maintenance of long-term relations with a firm's existing customers and stakeholders and terminating some of these relationships where necessary in a manner that will be of benefit to all the parties involved (Harker, 1999; Grönroos, 1996). RM fosters partnerships, which ultimately lead to profitable exchanges (Kanagal, 2009); and helps firms, like banks, to acquire, retain and adequately satisfy their customers. Extant research has posited that there is relatively limited research on firms' RM activities online and how it influences other relationship marketing outcomes (Ghazi, Muhammed, Khalil, Fwwaz, & Raed, 2013; Huang & Shyu, 2009). For instance, some scholars have averred that there is a need to explore the complementarities between firms' online relationship building efforts and other relationship marketing outcomes, including the enhancement of customer loyalty (Brun, Rajaobelina & Ricard, 2014). As well, others such as Fam, Foscht and Collins (2004) have postulated the relevance of studying the incorporation of firms' relationship marketing activities online with other organizational practices and outcomes, to the advancement of existing knowledge on the role and potential of internet technology in relationship marketing. Authors such as Mukherjee and Nath (2007) and Kassim and Abdulla (2006), in response to the above issues, have made attempts at utilizing the Commitment-Trust Theory of Relationship Marketing (Morgan & Hunt, 1994) often with some minor modifications, to study the outcomes of firms' relationship marketing activities online. Their contributions, though valuable, tend to culminate in one result that the model can be further extended to measure the various aspects of firm-customer relationships online adequately.

More so, in broadening the appreciation of online relationship marketing practices, some authors have conceptualized and proposed certain activities - engagement and interactivity - which impact firm-customer relationships in the online context (Guo, 2014; Farquhar & Rowley, 2006). However, the relationships between these activities and customer commitment, trust and loyalty are yet to receive attention in Online Relationship Marketing (ORM) research. Also, the three dimensions of customer commitment - affective, calculative and normative - have often been overlooked in online customer relationship studies (see McCallum, Forret & Wolff, 2014). Though existing literature indicates that the ramifications of each of these three dimensions of commitment differ, they have often been lumped together and studied as one construct (see Jones, Fox, Taylor & Fabrigar, 2010). Hence, this study asserts that if online relationships are studied from the specific perspectives of customer commitment, it will arguably yield new insights. Calculative commitment is the focus for this current study since it considers the competitiveness of the firm's value proposition and is a significant predictor of customer churn rates (Gustafsson, Johnson & Roos, 2005).

On the other hand, there is relatively less representation of ORM research from developing economy contexts. Few studies have shared valuable insights that this study builds on (Mahmood, Kastner & Lartey, 2017; Boateng & Narteh, 2016; Lee, Lee, Taylor & Lee, 2011). For example, using the Ghanaian banking sector, Boateng and Narteh (2016) explored the relationships between ORM practices –

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

engagement, interactivity, advocacy and personalization – and affective customer commitment, as well as the mediating role of trust. The study suggested that trust mediates the influence of engagement and personalization on affective commitment; while advocacy and collaboration have a direct relationship with affective commitment. The study calls for more studies exploring other dimensions of commitment and relationship outcomes, including customer loyalty. Then again, Mahmoud *et al.* (2017) explored the practice, challenges, and benefits of Internet-based relationship marketing (RM) within the Ghanaian telecommunication industry. The authors suggest that since ORM practices constantly evolve, more research is needed to compare these practices across industries.

Consequently, the purpose of this study tends to be in response to the above calls. The study seeks to explore the relationship between ORM practices or activities (engagement and interactivity), calculative commitment and customer loyalty; as mediated by online trust within the Ghanaian banking industry. The mediating role of trust in this instance is accentuated due to the key mediating role it is purported to play in successful relational exchanges, based on the Commitment-Trust Theory (Morgan & Hunt, 1994).

The paper is structured as follows. It consists of an introduction presented above, and a section on literature review and hypotheses culminating in a conceptual framework; followed by the research design. Next, the empirical results are presented, which discusses the findings of the measurement model and the structural model. Finally, the results are discussed, in addition to some managerial implications and future research directions.

LITERATURE REVIEW AND HYPOTHESES

Online Relationship Marketing Activities

ORM refers to the use of multifaceted interactive web features and tools on the internet to support relationship marketing in firms (Gan, Sim, Tan & Tna, 2007; Harker, 1999). Firms perform several activities online, including engaging customers through online content creation, as well as interacting with them online in real time. Online RM activities refer to the relationship activities afforded by internet applications in an online platform. Several different activities have been proposed in extant literature. These activities can be broadly categorized as: engagement, interactivity, personalization and collaboration. Engagement refers to the building of connections between the customer and the organization's offerings and services (Guo, 2014). Interactivity refers to the establishment of dialogue between the customer and the organization, which involves the sharing of information (Gan *et al.*, 2007). Personalization refers to the tailoring of interactions or information to establish transactions which are unique to the customer (Guo, 2014; Farquhar & Rowley, 2006). Collaboration establishes environs where customers become knowledgeable partners in firm value creation processes, feel assured and build bonds with other customers and also with the firm (Guo, 2014; Cobos, Wang & Okumus, 2009). The ORM activities are often conceptualized as antecedents to relationship outcomes – such as customer loyalty and behavioral intention, and they are usually mediated by customer commitment and trust (Bart, Shankar, Sultan & Urban, 2005; Gan *et al.*, 2007; Guo, 2014). It is also argued that since RM activities are uniquely developed, their applicability may differ across online communities, service settings and different industries (Ioannou & Zolkiewski, 2009; Farquhar & Rowley, 2006). As such, more research is needed to better understand the conduct of these activities and the impact on relationship outcomes.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

This study contributes to the literature by exploring the conduct of two ORM activities – engagement and interactivity - in the Ghanaian Banking industry. The rationale for the study setting is that the banking industry is arguably relationship oriented, information intensive and primarily affected by internet-oriented technological developments, making it opportune for a study, which will explore the applicability of ORM activities (Proença, Silva & Fernandes, 2010). A previous study in the Ghanaian Banking industry examined ORM activities of engagement, interactivity, advocacy and personalization and affective customer commitment (Boateng & Narteh, 2016). However, the present study takes a closer look into the impact of two ORM activities on customer loyalty as mediated by online trust and calculative commitment. Worthy of note is that the need for a study exploring the mediating roles of online trust and calculative commitment has been echoed in previous literature (Boateng & Narteh, 2016; Nusair, Bilgihan, Okumus & Cobanoglu, 2013). To recap, to allow for a more thorough examination of ORM activities, mediators and outcomes, only two ORM activities – engagement and interactivity – are explored in this study.

Engagement can be explained as the level of intensity with which individuals participate and connect with a firm's activities online (Vivek, Beatty & Morgan, 2012). Engagement online typically takes place on social media and is demonstrated through specific customer behaviors including 'liking', sharing and commenting on content posted on the firm's social media pages (Kabadayi & Price, 2014). Interactivity, on the other hand, captures the degree to which dialogue is established between firms and their customers online, through the sharing of information (Fang, 2012). Mollen and Wilson (2010) aver that reciprocal or two-way communication plays a pivotal role in the process of interactivity. Interactivity has been found to play a critical role in eliciting positive behavioral intentions among customers online (Jeon, Jang & Barrett, 2016).

The Signaling Effect of ORM Activities

The Signaling Theory (Connelly, Certo, Ireland & Reutzel, 2011) is utilized in this study to explain the signaling role of ORM activities (engagement and interactivity) in influencing firms' customer relationship marketing outcomes. Signaling theory comprises three primary elements, in addition to two other factors, which are presented by Connelly *et al.* (2011) in the form of a timeline. The timeline depicts two main actors - the signaler and the receiver, the signal itself, as well as feedback from the receiver which is sent back to the signaler; all of which co-exist in a signaling environment. A signal refers to an action or artefact that communicates information about the characteristics of an organization, product or person to the customer, which enables them to assess their reliability and legitimacy (Mavlanova, Benbunan-Fich & Koufaris, 2012). It comprises positive information that is purposefully communicated in order to portray the signaler's positive attributes and mask any potential weaknesses (Connelly *et al.*, 2011; Certo, 2003). Well received signals can influence the perceptions of trust, as well as the purchase intentions of the target audience (Mavlanova, Benbunan-Fich & Lang, 2016). A signaler, as explained in terms of consumer research, generally connotes an insider (often the organization's management) who owns information about the underlying 'quality' of a person, product or firm, which they wish to communicate to their customers (Ho & Wei, 2016; Connelly *et al.*, 2011). The receiver is the primary target of the signaler's output and is continually scanning the environment for signals from firms with which to make accurate purchase decisions (Connelly *et al.*, 2011). For the objectives of the signaler to be achieved, the signals sent need to be received and correctly understood by the receiver for it to have an effect (Mavlanova *et al.*, 2016). Per Connelly *et al.* (2011), signalers and receivers often have

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

somewhat competing interests. Hence, the need for what authors like Durcikova and Gray (2009) refer to as signal honesty, where the underlying quality portrayed through the signal is one that is genuinely possessed by the signaler, so that the receiver is not misled.

Feedback involves the sending of counter signals from the receiver to the sender. It is not enough that the signaler successfully sends a signal to the receiver; the signaler also expects to receive some information back from the receiver to ascertain whether their signals have been interpreted as they intended (Taj, 2016). Hence, the inclusion of the feedback component in the signaling theory. The signaling environment refers to the context within which the signaling process takes place, fostering interaction between the various elements in the process. It is pertinent that the signaling environment is free of any form of 'noise' that could hinder the signaling process (Taj, 2016). Potential sources of 'noise' may include opposing signals from the signaler and competitors, as well as certain characteristics of the receiver. Any of these can bring about distortions in the signaling environment, which can affect how the signal is transmitted, as well as the receiver's interpretation of signals received; all of which is of key importance to the success of the entire signaling process.

Some researchers have used the Signaling Theory to understand information technology (IT) enabled signals sent by firms (the signalers), and the impact that these IT signals have on customer perceptions, as well as their attitudes and behaviors (Mavlanova *et al.*, 2016; Benlian & Hess, 2011). The theory, therefore, provides a framework that depicts how customers rely on informational cues or signals in the form of actions or artefacts that reliably communicate unobservable product or firm quality, when forming judgments on how best their needs may be satisfied (Kirmani & Rao, 2000; Boulding & Kirmani, 1993). It allows for the exploration of ORM activities as informational cues utilized by firms to influence customer perceptions and behavior. In applying the theory, Benlian and Hess (2011) noted that further research was required to investigate which specific online features and activities that are used as signals, have a positive impact on customer perceptions and behavior. Additionally, Mavlanova *et al.* (2016) call for research on online signals to be studied in varied contexts, using diverse online applications; noting that it will not only help to extend signaling theory research, but also generate interesting insights to inform online business strategy.

In this study, the signaling theory is combined with the Commitment-Trust Theory to examine the complementarities between firms' ORM activities (Engagement and Interactivity) and other relationship marketing outcomes; including Online trust, Calculative commitment and Customer loyalty. The Commitment-Trust Theory by Morgan and Hunt (1994) tends to be the dominant theory in ORM research. The theory espouses that relationship benefits, termination costs, shared values, communication and opportunistic behavior are the five precursors of relationship commitment and trust, which lead to five relationship outcomes: acquiescence, propensity to leave, cooperation, functional conflict and decision-making uncertainty — thereby placing relationship commitment and trust as key mediating variables.

The ensuing sub-sections present the hypotheses and conceptual model of the study.

Hypotheses Development

Online Trust, Engagement and Interactivity

Online trust is a component that contributes significantly to the overall success of firms' marketing activities in the online context (Bleier & Eisenbeiss, 2015). Literature argues that online trust is established mainly through customers' self-perceptions, based on their direct experiences and interactions with the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

firm online (Bock, Lee, Kuan & Kim, 2012; Kim, Ferrin & Rao, 2008). For instance, Etemad-Sajadi (2016) posits that online interactivity in real-time has a significant positive influence on online trust and customers' intentions to patronize a given brand. Furthermore, Brodie, Ilic, Juric and Hollebeek (2013) found that the customer engagement process often leads to customer commitment and trust. Therefore, it is hypothesized that:

H_1: Engagement directly influences Online trust
H_2: Interactivity directly influences Online trust

Online Trust and Calculative Commitment

Calculative commitment embodies the customers' expectations of immediate or future rewards, as well as the cost contingencies resulting from staying with their current service provider, as compared with available alternatives (Sumaedi, Juniarti, & Bakti, 2015). Thus, in this instance, rationale dominates over emotion when it comes to customers' assessment of their relationship with the firm. Trust has been identified in relationship marketing literature to have a significant impact on customer commitment (Tsao & Hsieh, 2012). Kassim and Abdullah (2010), for instance, assert that trust is a critical driver of commitment among customers who are in long-term relationships with their service providers online. Thus, it is hypothesized that:

H_3: Online trust directly influences Calculative commitment

Online Trust and Customer Loyalty

Customer loyalty can be defined as the general attachment of a buyer to a product or service (Wang & Wu, 2012). It is demonstrated through a variety of actions and comprises both attitudinal and behavioral elements. These are usually exhibited through the customer's intention to re-purchase or re-patronize a brand's products and services, as well as their desire to maintain a lasting relationship with the service provider and recommend their brand to others (Picón-Berjoyo, Ruiz-Moreno & Castro, 2016; Srivastava & Kaul, 2016). Although online trust is averred to have a positive effect on customer loyalty, the way trust may be gained online, and the potential effect it may have on firms' outcomes is yet to be fully understood (Fullerton, 2014; Urban, Amyx & Lorenzo, 2009). Hence, this study hypothesizes that:

H_4: Online trust directly influences Customer loyalty

Calculative Commitment and Customer Loyalty

Cater and Zabkar (2009) assert that customer loyalty is a consequence of all the three dimensions of commitment; namely Affective, Normative, and Calculative commitment. However, Bilgihan and Bujisic (2015) found calculative commitment to have a distinct influence on customer loyalty. Thus, the following hypothesis:

H_5: Calculative commitment directly influences Customer loyalty

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

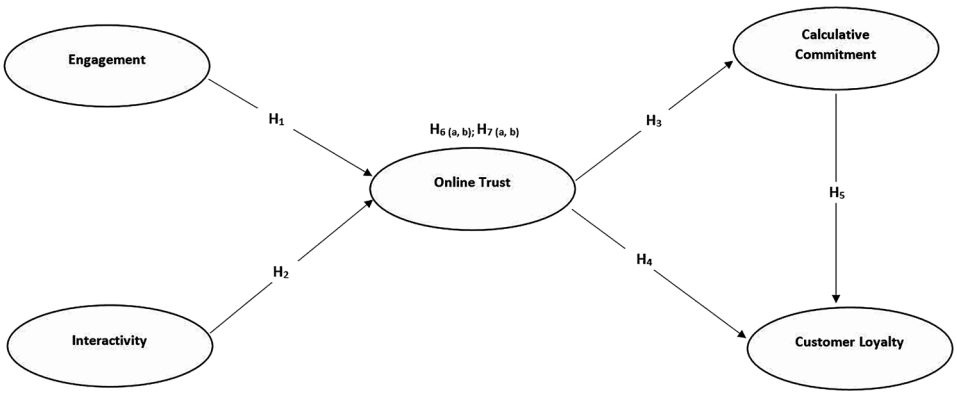
Mediating Role of Online Trust

Over the years, scholars such as Jeon *et al.* (2016) and Wang, Law, Guillet, Hung and Fong, (2015) have proffered the mediating role of online trust in firm-customer interactions within the online context. Wang *et al.* (2015), for example, as part of their research, statistically established the mediating role of online trust between hotel website quality and customers' intentions to place a booking online. This finding is corroborated by Hsu, Liu and Lee (2010), who determined that the influence of a firm's overall image on customer behavioral intention, must be mediated through customer commitment and trust. However, the mediating effects of trust in relation to online relationship strategy has not been completely examined. As such, it is hypothesized that:

H_{6a}: Online trust mediates the relationship between Engagement and Calculative commitment
H_{6b}: Online trust mediates the relationship between Engagement and Customer loyalty
H_{7a}: Online trust mediates the relationship between Interactivity and Calculative commitment
H_{7b}: Online trust mediates the relationship between Interactivity and Customer loyalty

Based on the discussion conducted in the literature review and the hypotheses postulated in the prior sections, Figure 1 presents the conceptual model for the study.

Figure 1. Conceptual model



RESEARCH DESIGN

Data Collection and the Sample

A quantitative research design was adopted, using the survey technique for data collection in order to examine the conceptual framework shown in Figure 1. The context of the study was set in the highly competitive Ghanaian banking industry (Boateng & Narteh, 2016), which has witnessed a surge in the adoption of web-based technologies such as emails and social media, with the sole intent of elevating the overall customer experience and maintaining their competitive edge (Acquaah & Yasai-Ardekani, 2008). The Ghanaian Banking industry is currently relatively saturated, with a combination of local and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

foreign multinational banks operating within the industry (Acheampong, 2013). The total number of banks operating in the industry as at 31st December 2016 was 33; 16 locally owned and 17 foreign controlled. 449 of the 500 questionnaires issued to bank customers who have previously interacted with their bank online, either via email, their website or through social media were returned. These responses were coded and entered into SPSS 20, following which the data was verified and screened for any form of error, missing data or outliers (Kline, 2011). The screening process revealed that several of the responses had more than 5% missing data. Therefore, it was decided to delete the responses that had missing values in various sections; resulting in the deletion of a total of 20 cases. Thus, excluding missing and unusable data, the resulting sample included a total of 429 respondents.

Table 1. Sample profile

Instrument

A self-administered survey questionnaire was used in collecting data from the identified sample. The questionnaire captured demographic information, as well as items relating to the antecedents, mediator and outcome variables presented in the conceptual framework. The measurement items were adapted from existing literature on Online Relationship Marketing (ORM) and Relationship Marketing (RM) and measured in the form of a Likert scale ranging from 1 (Strongly Disagree) to 5 (Strongly Agree). Engagement was measured using a ten-item scale adapted from the works of Guo (2014) and Cobos, Wang and Okumus

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(2009). Interactivity was measured using eight items adapted from the works of Cobos *et al.* (2009) and Farquhar and Rowley (2006). Online trust was assessed using nine items developed based on the work of Bilgihan and Bujisic (2015) and Brun *et al.* (2014). Calculative commitment was measured by seven items in this study, based on Brun *et al.* (2014) and Dabholkar, van Dolen and de Ruyter (2009). While Customer loyalty was measured using nine items adapted from Labrecque (2014) and Huang and Shyu (2009).

EMPIRICAL RESULTS

Structural Equation Modelling (SEM) was utilized in analyzing the data collected, as well as testing the hypothesized relationships (Kumar, Manrai & Manrai, 2017; Byrne, 2010). The two-stage approach to SEM recommended by Anderson and Gerbing (1988) was performed, using the maximum likelihood extraction method in order to estimate a measurement model and a structural model in Amos 22.

Measurement Model

The measurement model was assessed by conducting a Confirmatory Factor Analysis (CFA) utilizing all the individual constructs in the model. The psychometric properties of the model constructs, along with the factor loadings of items measuring each construct are presented in Table 2. Each variable was tested for reliability, convergent and discriminant validity; and as can be observed from Table 2 all the factor loadings are well above the cut-off point of 0.5 (Ladhari, Souiden & Dufour, 2017). Also, the Composite Reliability (CR) and Average Variance Extracted (AVE) values are above the required minimum values of 0.6 and 0.5, respectively (Bagozzi & Yi, 2012). As such, the reliability and convergent validity of the constructs are confirmed. To provide support for discriminant validity, the square root of the AVE of each construct should be greater than the correlation between the construct and other constructs in the model (Kumar *et al.*, 2017; Fornell & Larcker, 1981).

Table 3 presents the correlation, mean and standard deviation of each construct, as well as the square root of their AVEs. It can be observed from the table that the square root of the AVE of the constructs, in all instances is greater than the correlation between the constructs, thereby, indicating discriminant validity. Furthermore, the resulting model produced good fit indices: Chi square (χ^2)/ Degrees of freedom (*df*) = 2, Tucker-Lewis Index (TLI) = 0.96, Comparative Fit Index (CFI) = 0.97, Incremental Fit Index (IFI) = 0.97, Root Mean Square Error of Approximation (RMSEA) = 0.05 (Schreiber, 2008).

Structural Model

After establishing that the measurement model depicted adequate levels of reliability and validity, the structural model was assessed in order to test the hypothesized relationships. This was done by examining the p values of the paths, as well as their standardized regression weights. Based on the above, the structural model showing hypotheses $\mathbf{H_1}$ to $\mathbf{H_5}$ was tested; the outcome of which is summarized in Table 4 and graphically presented in Figure 2. The test of the general fit of the model yielded Chi square (χ^2)/ Degrees of freedom (*df*) = 2.2, with a p value less than 0.001. The value of the Tucker-Lewis Index (TLI) was 0.96, the Comparative Fit Index (CFI) was 0.97, the Incremental Fit Index (IFI) was 0.97, and the Root Mean Square Error of Approximation (RMSEA) was 0.05; all of which fall within the acceptable cut-off limits (Schreiber, 2008).

***p < 0.001

As shown in Table 4, Interactivity was positively and significantly related to Online trust (**$\beta = 0.69$**, **$p < 0.001$**) and Online trust was found to be positively and significantly related to Calculative commitment (**$\beta = 0.33$**, **$p < 0.001$**), as well as Customer loyalty (**$\beta = 0.32$**, **$p < 0.001$**). Calculative commitment was also positively related to Customer loyalty (**$\beta = 0.62$**, **$p < 0.001$**). Nonetheless, Engagement was not significantly related to Online trust. Thus, hypotheses **H_2** to **H_5** were supported. But, hypothesis **H_1** which examined the relationship between Engagement and Online trust was rejected.

Table 4. Summary of hypotheses test

Mediating Role of Online Trust

Table 5 depicts the mediating role of Online trust between the ORM activities (engagement and interactivity), calculative commitment and customer loyalty. This was tested using the bootstrap technique in Amos, as advocated by Preacher and Hayes (2008). As observed from the table, the outcome of the structural model shows that the direct relationships between interactivity and calculative commitment, as well as interactivity and customer loyalty, are both significant without online trust as a mediator. However, the indirect effect of interactivity on calculative commitment and customer loyalty, respectively, through online trust as a mediator are both significant. This provides enough evidence for the partial mediation of online trust in the relationship between interactivity and calculative commitment, as well as that between interactivity and customer loyalty. Thereby, substantiating only hypotheses **H_{7a}** and **H_{7b}**.

DISCUSSION OF FINDINGS

The findings highlight the impact of ORM activities (engagement, interactivity) on calculative commitment and customer loyalty; as well as the mediating role of online trust in these relationships between firms and their customers within the Ghanaian banking industry. However, the findings failed to establish a relationship between engagement and online trust ($\mathbf{H}_1$) indicating that engagement does not exert any significant influence on bank customers' online trust. This finding came as no surprise since previous research by Hsu, Chiang and Huang (2012), as well as Wu and Chang (2005) suggests that it is only when trust exists in an online community that the customer can meaningfully engage. Thus, these findings suggest that bank customers appear to be less engaged online (see Table 1).

Though Ghanaian banks, the signalers, are providing information online, the signals are either not reaching the customers, the receivers, through the appropriate medium, or not being correctly understood by the receivers to have an effect or draw out a response. According to the tenets of signaling theory, for the objectives of the signaler to be achieved, the signals sent need to be received and correctly understood

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

by the receiver in order for it to have an effect (Mavlanova *et al.*, 2016). Extant literature also argues that among other online platforms, customer engagement primarily takes place on social media (Wirtz *et al.*, 2013). Nevertheless, from Table 1, one finds that social media is the least used medium for communication with customers. Far less than 50 per cent of the customers (38.5%) surveyed communicate with banks or obtain information through social media, while that of website and email were 79% and 100%, respectively. In effect, social media is less used by Ghanaian banks.

Much of the efforts for ORM activities of Ghanaian banks is through the websites of banks and emails. It could be inferred that the lack of an engagement focus exhibited by the Ghanaian banks could be associated with the risks, security and privacy issues related to the use of online technologies for communication. For websites and emails, the signals in the form of data privacy assurances and secure transaction mechanisms like Secure Socket Layer (SSL) encryption, as well as usability functions like Help tabs and Frequently Asked Questions are used by Ghanaian banks to reinforce customer perceptions of quality. Thus, signals for security for websites and emails are fairly certain (Mavlanova, Benbunan-Fich & Koufaris, 2012; Li, Srinivasan & Sun, 2009); but that of social media is still emerging (Cheng, Fu, & de Vreede, 2017).

Hence, in contexts where cybercrime is quite prevalent (see Boateng, Longe, Isabalija, & Budu, 2011) and internet banking is growing out of its nascent stages (Boateng & Narteh, 2016), Ghanaian banks are likely to be more cautious in their online activities, especially with technologies that they are quite uncertain about. In the tenets of signaling theory, Ghanaian banks are more likely to prefer 'environments' which are assessed or perceived to be free of any form of 'noise' that could hinder their signaling process (Taj, 2016). In précis, engagement as an ORM activity is assessed to be low by Ghanaian bank customers and presently does not influence customer commitment, online trust and customer loyalty. However, per the responses captured through open-ended questions in this study, customers expect banks to leverage social media to engage more with them.

Nonetheless, hypotheses $\mathbf{H_2}$ to $\mathbf{H_5}$ were proven; indicating that interactivity has a significant positive impact on online trust. It also indicates that online trust positively influences calculative commitment and customer loyalty; while calculative commitment has a direct influence on customer loyalty. Interactivity enables banks to mitigate the negative effects of the lack of physical interaction online by providing semblances of a human presence in customer dealings with them online. These semblances communicate an air of reliability and dependability to the customer, as proffered by the Signaling theory. Thereby, corroborating the findings of Beuckels and Hudders (2016) on the positive effects of interactivity on customer attitudes.

Regarding the relationship between Online trust and calculative commitment, literature identifies both trust and commitment as essential components in any long-term relationship (Lin, Weng & Hsieh, 2003; Morgan & Hunt, 1994). Online trust is considered to be of prime importance when transacting over the internet due to issues of security and privacy in the online environment. Once bank customers are convinced of the efficiency and reliability of the bank's online channels, they are sure to remain loyal into the foreseeable future. Banks, therefore, need to enhance their trust-inducing measures online, to endear their customers to remain loyal, as opined by Ladhari and Leclerc (2013).

Even so, it is acceptable to find some customer segments committed to their service provider for calculative reasons such as high switching costs and unique product and service benefits (Rajaobelina, Brun & Toufaily, 2013). Thus, a customer will most likely remain loyal to their bank if they are locked-in by some form of contract or lack of viable alternatives. In this instance, their loyalty to their bank is not because they are emotionally attached to them, but for purely rational and economic reasons (Lariviere *et*

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2014; Sashi, 2012). This assertion is supported by the outcome of the current study, which unearthed a significant positive relationship between customers' awareness of the costs associated with leaving their bank (calculative commitment) and their loyalty to them.

In addition, the findings provide evidence for online trust's partial mediation of the effect of interactivity on calculative commitment, and that of interactivity on customer loyalty ($\mathbf{H_{6a}}$ to $\mathbf{H_{7b}}$. This implies that an increase in online trust will likely influence a customer's decision of whether or not to switch banks based on their interactivity. Likewise, an increase in online trust will, to some extent, impact bank customers' decisions to remain loyal to their bank based on how interactive their bank is with them online. These outcomes confirm the findings of previous studies (Chen, Griffith & Shen, 2005; Bart *et al.*, 2005) which provide similar results for testing such relationships. For instance, Bart *et al.* (2005) found that online trust partially mediates the relationships between website characteristics and customer behavioral intent.

Therefore, customers' perceptions of how well a bank's online channels can perform their required functions, can contribute significantly to their need to stay committed to their bank, as well as their intentions to remain loyal. Hence, one concludes that ORM activities pay; as such, instituting measures to increase interactivity would generally increase online trust, calculative commitment, as well as customer loyalty.

CONCLUSION

The study advances our understanding of the online signals sent through banks' ORM activities, namely engagement and interactivity and how they affect customer loyalty, as well as customers' perceptions of online trust and calculative commitment. The findings suggest that signals communicated through ORM activities, particularly interactivity per the Signaling theory, is indeed beneficial in influencing customers' online trust, calculative commitment and loyalty. The results substantiate the mediating role of online trust in Ghanaian banks' ORM activities, where online trust was found to mediate the impact of interactivity on calculative commitment, as well as the impact of interactivity on customer loyalty. This confirms one of the main assumptions of the Commitment-Trust Theory (Morgan & Hunt, 1994). Hence, together, the Signaling theory and the Commitment-Trust theory enable us to understand the complementarities between banks' online relationship building efforts and other relationship marketing outcomes.

Banking service delivery online has become a major topic of discussion among scholars in recent years; especially in Sub-Saharan Africa (Blankson, Ketron & Darmoe, 2017; Tarus, 2015; Narteh & Owusu-Frimpong, 2011). The introduction of online technology into banking in Ghana has precipitated several advances in the industry; leading to the introduction of various innovative banking products and customer solutions. The outcome of this study corroborates this by highlighting the role of online technology in relationship marketing, which enhances customer engagement, builds trust and fosters customer loyalty. This study enables banks in Ghana, and perhaps, other sub-Saharan African countries to recognize the nature of their online interactions with customers, as well as gain an understanding of the appropriate policies and measures necessary to effectively harness these technologies in their interactions with customers. Further, though website and email emerged as the most predominantly used internet applications in ORM in the banking industry, customers also expect banks to engage with them through social media. Social media has the potential to improve upon the current levels of bank-customer

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

interactivity online. Banks should, therefore, develop strategies to leverage social media appropriately in order to engage and interact better with their customers.

Finally, most of the studies on ORM are done from the perspective of the customer; future research may consider, through a qualitative approach, exploring the decisions and strategies which underpin ORM activities of firms. Such a study may explore the roles of relationship managers (who may be offline) and employees who manage content on internet applications. Since this study used cross-sectional data, a longitudinal study on how relationships are developed online over time may offer an understanding of the influences of time sequence upon the relationships discussed in this study. Future research could also be directed at other sectors to explore the applicability of the underpinning theories further, as well as to fine-tune the conceptual model used.

ABSTRACT

In the hyper-competitive Indian airline industry, the low-cost carriers as well as full-service airlines are in dire need of innovative marketing strategies to engage their customers. To understand the dynamics behind the process of customer engagement, the purpose of this paper is to gain insights into the lived experience of consumers about their online air-ticket bookings experiences. In total, 60 frequent air travellers were approached to participate in the study and the self-completion diary method was incorporated to record their ticket booking experiences. The responses recorded in the diaries were analyzed on the basis of their content from which eight themes were derived. The findings bring forth the importance of hedonic experiential values along with utilitarian experiential values toward the engagement of customers during the online air-ticket booking process. The current study is one of the pioneers in conceptualization of customer engagement as a third-order construct by uncovering the sub-dimensions of the second order factors—utilitarian and hedonic experiential values.

INTRODUCTION

Consumer buying behavior has changed drastically with the advancement of technology. The growth of the internet and e-commerce has brought revolution by connecting more than two billion people worldwide (Buhalis & Law, 2008). The impact of internet on the global economy is immense with its contribution of around three percent to the global GDP as stated in a report by McKinsey Global Institute (Manyika & Roxburgh, 2011). The influence of internet on the developing countries has also been reported, and it has been observed that nearly 50 percent of the internet users thrive beyond the advanced economies such as India, which is developing quickly and is one of the emerging economies. India is characterized by significant economic potential, social, and cultural diversity. Emerging economies have been defined as those economies that comprise of the fast-growing developing markets (Gnanasambandam et al., 2012; Khanna, Palepu & Sinha, 2005). The marketers are still struggling for effective marketing strategies to reap benefits from this market (Ramamurti 2008). The reason behind it is that these markets comprise of prosperous middle-class consumers who are different from the consumers of the developing market with regard to factors like socio-economic demographics (Biswas & Roy, 2015). Therefore, they exhibit different consumption pattern and consequently the motives behind their purchase decision varies. Thus, we want to enrich this body of literature by incorporating unique characteristics of one of the emerging markets, i.e., India, which will provide guidance related to the country-industry-specific research.

Further, it is seen that about 120 million people use internet in India, which is a striking example of the growth potential of internet usage, and thereby making it the third largest internet user base in the world (Dart Consulting, 2014). Interestingly, though India is adopting internet at a significant pace, a mammoth chunk of its population (i.e., 90 percent of its population) is not connected and there is a scope of adopting the internet by the majority of its population (Dart Consulting, 2014; Gnanasambandam et al., 2012).

In this era of technology advancement, e-commerce becomes the new trend and the need of the day, which has motivated scholars to explore and examine factors related to the engagement of the consumers for online purchases (Buhalis & Law, 2008; Pappas, Kourouthanassis, Giannakos, & Lekakos, 2017; Turban et al., 2018). Online purchase behavior is a well- established phenomenon. Consumers are moving to online shopping platform for various reasons such as excitement, enjoyment, time saving, discounts and benefits, wider choice and comparison, and so forth (Anderson, Knight, Pookulangara, & Josiam, 2014; Pappas et al., 2017). The motives behind online purchase behavior may vary and is based on the types of consumer. Past studies have classified consumers on the basis of two types of shopping motivations — utilitarian and hedonic (Anderson et al., 2014; Babin, Darden, & Griffin, 1994; Childers, Carr, Peck, & Carson, 2001). Utilitarian motivation is associated with the benefit that consumer gets from consuming a product or service to accomplish a task, whereas, hedonic motivation is associated with the experience gathered from consuming a product or service (Anderson et al., 2014; Babin et al., 1994; Childers et al., 2001). These utilitarian and hedonic consumers display different shopping patterns. A consumer may be driven by a utilitarian or a hedonic motive or by both. Thakur (2016) conceptualized that customer engagement comprises experiences that arise out of hedonic and utilitarian values sought by the consumers from a product or services. Ultimately, the motives (i.e., hedonic or utilitarian) that engage consumers and influence their choice behavior are important from a marketer's perspective (Anderson et al., 2014; Devedi, Sujatha & Pathak, 2017; Pappas et al., 2017).

The current research will explore the utilitarian and hedonic motivations of online consumers who are engaged in the purchase of airline e-tickets in India. Elias et al. (2015) stated that the airline e-ticketing

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

industry is one of the fastest growing industries in the world. Moreover, the Internet and Mobile Association of India [IAMAI] reported that online travel booking holds a major share of the spending related to Digital Commerce, i.e., about 61 percentage, and air ticket booking is amongst the top categories in online travel space. Past studies have noted that the majority of online shopping is associated with the purchase of air tickets (Babin et.al, 1994; Escobar-Rodríguez Carvajal-Trujillo, 2014; López-Bonilla & López-Bonilla, 2015), but there is scarcity of literature that explores the motives behind the engagement of airline e-ticket consumers from their lived experience, especially in the contextually rich market such as the emerging market of India. Hence, in this study, we conceptualized engagement in the airline e-ticket as the experiences that arise out of hedonic and utilitarian values sought by the consumers from an airline e-ticket consumption. The profile of consumers in India varies on the basis of value system, information quality of the airline e-ticketing website, and the perceived risks associated with the online customer engagement (Devedi et al., 2017; Thakur, 2016). Hence, it is possible that the consumers in India hold different motives for engaging in the purchase of e-tickets. There is a paucity of studies exploring the conceptualization of customer engagement (Brodie, Llic, Juric, & Hollebeek, 2013), thus, we endeavor to enhance this body of literature by examining the sub-dimensions of the two types of motives (i.e., hedonic and utilitarian) behind the engagement of online consumers with the airline ticket booking portals.

The requirement of in-depth understanding of these factors is highly palpable in the Indian airline industry. The Indian airline industry is undergoing several changes due to multiple players, low revenue structure, high operating cost, and volatile economic conditions (Brodie et al., 2013; Rangarajan & Prasad, 2014). The industry witnesses severe completion for acquiring customers (Hollebeek, Glynn, & Brodie, 2014). The findings of this study will aid the airline companies to understand the specific utilitarian and hedonic motivations behind the engagement of their customers toward the online purchase of air tickets. The study will provide insights into the online e-ticketing customer engagement, which can be capitalized by the airline firms to achieve continuous improvements in their services, offers, website management, and it will keep them ahead of the cut-throat competition (Brodie et al., 2013; Thakur, 2016).

LITERATURE REVIEW

Online shopping behavior has gained momentum a few decades back with the advancement in technology (Thakur, 2016; Bordie et al., 2013). Scholars have tried to understand the shopping behavior from various perspectives. For the ease of understanding the shopping patterns, consumers are categorized on the basis of their actual patronage and shopping behaviour (Stephenson & Willet, 1969; Verhoef, Reinartz, & Krafft, 2010) and the enjoyment derived from shopping (Bellenger & Korgaonkar, 1980; Thakur, 2016). Tauber (1972) for the first time explored the motivation behind shopping behaviour (To, Liao & Lin, 2007) and basically believed that "people shop not only for the utilitarian value of the products but also for the satisfaction derived during the shopping process" (To et al., 2007, p. 775). These two shoppers' motivations are rooted in the concept of "value", which is created by the holistic experience of shopping and not simply through the acquisition of product/services (Babin et. al., 1994). Holbrook and Hirschman (1982) corroborated that the motivation behind shopping should not be observed from the objective perspective alone like "focusing on an object, its price, or the functional utility provided by that object", as it will be too narrow concept "to account for all value provided by consumption experiences" (Babin et. al., 1994, p. 645). This new perspective of dichotomized motivations of hedonic

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and utilitarian behind shopping by Holbrook and Hirschman (1982) brought the paradigm shift from the functional perspective of shopping to the experiential shopping perspective. One of the subsequent studies on this perspective was carried out by Babin et al. (1994), who illustrated that "shopping with a goal" can be distinguished from "shopping as a goal" (p. 647). To explain this phenomenon, researchers conducted a qualitative inquiry on the gift purchase behavior during the festive season of Christmas. The finding of this study explicated that for some people gift purchase during Christmas is a chore, while for such an exuberant occasion, others might enjoy the whole experience of gift shopping.

Studies on this dichotomized motivation of hedonic and utilitarian are also growing in the online contexts, but researchers like Loiacono, Watson, and Goodhue (2007) decreed that online environment is not similar to the traditional retail environment. The reason is that theories developed in the face-to-face context are inappropriate for the 'idiosyncratic' online environment, where online shopping involves unique interaction of 'information system' and 'marketing' (Lociacono et al., 2007). One of the comprehensive works on the factors affecting hedonic and utilitarian motives in the online context has been conducted by To et al. (2007), who found that utilitarian motivation is affected by convenience, cost saving, information availability, and selection, whereas, hedonic motivations are affected by adventure, authority, and status. Charles et al. (2010) further examined the utilitarian and hedonic motives of consumers in the context of online shopping and concluded that online shopping experience can be enhanced through hedonic factors related to aesthetically rich shopping environment. In a similar vein, Kim and Eastin Mathew (2011) studied consumers' online shopping behaviors and tested the effect of hedonic shopping motivation. The findings indicated that hedonic shopping motivation is the major predictor of information seeking behavior and impulse buying behavior of consumers. Michael (2006) further conducted qualitative research on the online behavior of consumers and identified the list of factors that affect the online buying behavior, which include convenience, time saving, and price advantage in comparison to other products and services. These factors derive and motivate online shopping. The exploration of hedonic and utilitarian motives was further explored through cross-cultural studies such as Özen and Kodaz (2016). The researchers found that Turkish consumers use online retailers to socialize with other consumers, whereas, the US people use the online retailers to relax.

Similarly, Pappas et al. (2017) suggested that there is an interplay of online shopping motivations with the experiential factors and these can be used to predict and increase purchase intention. These experiential factors generate values for customers that help in obtaining online customer engagement (Thakur, 2016). Customer engagement has been conceptualized in varied forms such as consumer and customer engagement (Verhoef et al., 2010), community engagement (Brodie et al., 2013), customer-brand engagement (Hollebeek et al., 2014), and customer-medium engagement (Calder, Malthouse and Schaedel, 2009). The variation in conceptualizations reflects that the construct is at an evolving state. Along with varied conceptualizations, there is diverse viewpoint on the definitions of customer engagement in the marketing literature. The definition of customer engagement varies from "a psychological process" (cf. Thakur, 2016; Bowen, 2008) to "a consumer's state of being occupied, fully-absorbed or engrossed" (cf. Thakur, 2016; Pham & Avnet, 2009). Marketing scholars have conceptualized customer engagement as a multi-dimensional construct (Brodie et al., 2013; Bowen, 2008; Calder et al., 2011; Thakur, 2016) that comprises cognitive, emotional, and behavioral aspects. Hollebeek et al. (2011) defined customer engagement with the brand as "the context-dependent state of mind characterized by specific levels of cognitive, emotional, and behavioral activity". Researchers have also focused on the experimental aspect of customer engagement, as Calder, Malthouse, and Schaedel (2009) suggested that customer engagement is "the sum of the motivational experiences consumers have with a media

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

product." Thakur (2016) showed that the customer uses an online platform to satisfy different motives and consequently perceive outcome values differently in different contexts.

From the above discussion, we can conclude that the existent literature connotes significant emphasis on hedonic and utilitarian motivations toward online customer engagement. However, studies hitherto have emphasized more on the quantitative validation of hedonic aspects of online customer engagement, rather than on personal experiences of consumers behind this hedonic consumption aspect. Hence, an in-depth qualitative inquiry is required to uncover the sub-dimensions of hedonic motivations along with the utilitarian motivations by exploring the deep-rooted psychological factors associated with e-ticketing consumer engagement experiences. Holbrook and Hirschman (1982) further concurred that the better way to understand mental events corresponding to any consumption act is to adopt introspective reports rather than resort to overt behavioral measures only.

Apart from the need to exactly specify the thoughts and believes of consumers about the hedonic and utilitarian motivations behind engagement into online purchases, there is a paucity of literature on the online air-ticket booking contexts of emerging markets such as India. According to Dart Consulting (2014) and Gnanasambandam et al. (2012), Indian consumers are adopting internet at a rapid pace, and there is an opportunity for Indian retailers to identify the prospects with online marketing. Indian consumers are experiencing a higher level of technology readiness in online ticket booking. With the advancement in technology readiness, it is found that consumers' motivations tend to move from utilitarian to hedonic motivations (Loiacono et. al. 2007). Thus, this study endeavors to qualitatively explore the sub-dimensions of utilitarian and hedonic motivations in understanding the conceptualization of customer engagement as a multi-dimensional construct in the context of online air-ticket booking for the emerging markets like India.

METHODOLOGY

Context

Online Airline Booking in India

The variables that motivate consumers to use the internet for shopping depends on the type of products or services (Phau & Meng, 2000). In the context of online air-ticket booking, past studies on technology readiness as well as technology acceptance revealed the importance of consumers' consumption motivations towards engagement with the booking web portals (Bigné et al., 2010; Llach et al., 2013; Al-maghrabi & Dennis, 2009; Koppius et. al., 2005; Kolsaker et al., 2004). Initially, engagement towards air-ticket booking was considered to be driven only by utilitarian motives. Technology advancement in these online portals is changing consumers' technology readiness and enabling the rapid technology acceptance. This study is one of its kinds to explore how technology readiness and technology acceptance is inducing the hedonic motivations along with utilitarian motivations behind engagement towards online ticket booking which is narrow to date was perceived to be only a utilitarian product in an emerging market such as India. Further, Boston Consulting Group said that a number of internet users in India have grown up to 580 million in 2018 from the existing 205 million in 2014 (IAMA, 2016). The report also stated that India is the second fastest growing market after China. Of this, air travel is the biggest contributor to this industry at 39%, while rail travel and hotel bookings follow it by accounting for 28%

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and 30% respectively. This makes air-ticket booking web portals as the largest selling category of Indian online travel market at 56% (Domestic Air Tickets – 50% and International Air Tickets – 6%), as per IAMAI and IMRB's "Digital Commerce" report (IAMA, 2016). Please refer exhibit 1 for the share of online travel in India.

Participant Selection

Since previous literature has not delineated the hedonic and utilitarian motivations of Indian airline consumers, this study followed an inductive approach to select information-rich cases (Corbin & Strauss, 2008). To this end, a purposeful snowball and criterion sampling technique was used to recruit airline consumers, as respondents, to explore their e-ticketing experience over a period of six months. Patton (1990) has recommended purposive snowball sampling and criterion technique as a technique to identify information-rich cases for qualitative inductive studies. Information-rich cases are those from which one can learn a great deal about issues of central importance to the purpose of the inquiry, thus the term purposeful sampling. Studying information-rich cases yields insights and in-depth understanding rather than empirical generalizations (Patton, 2002, p. 230). Thus, information-rich cases. allows finding a more closely defined group of participants for whom the research objectives will be relevant. The respondents, therefore, were the frequent air travelers located across three major cities in India namely; Kolkata, New Delhi and Hyderabad. These cities are the major metropolitan cities of India and, most of the companies have their presence in these cities. Further, in these cities, the preferred mode of traveling among the business executives are by air given that the usage of internet services for online purchases are concentrated mostly in these regions. Selection of the cities was based on the ease of accessibility to a large online airline booking consumers, representing different parts of the country. These respondents were the business executives working in different hierarchical levels across different jobs and industries. They were categorized as frequent travelers based on the frequency of their travel visits in the last three months. The basis was that these executives would have traveled between three to five times in a month. The tickets for these travels were booked online. We ensured the ethical research practice by maintaining the anonymity of the respondents. For this consent was taken from the respondents for their participation. They were assured for the anonymity of their responses and that their participation is voluntary. Lastly, we also inform them that their responses will be used purely for academic purpose.

Data Collection Through Self-Completion Diary Method

The data were collected using self-completion diaries (Zeba & Mohnaty, 2019; Bolger et al., 2003). Diary approach gave consistency in recording the data that might have been missed out at the time of recall, as it entails real-time involvement (at or around the time of purchase) of the respondents, with minimal intervention from the researcher (other than distributing and collecting the diaries) (Bryman, 2015). The lack of intervention facilitated the subjective freedom to the respondents to express their opinions when booking tickets online. In effect, diarizing response near the time of purchase also decreases delay in time which potentially result in response bias (Bolger et al., 2003). We followed the procedure suggested by Alaszewski (2006) and in the first step of the diary method, a dairy was given to each participant and was briefed about documenting their experiences of air-ticket bookings. The respondents were also informed about the timeline for which they were supposed to record their air-ticket booking experiences as well as the deadline for returning the dairy to us. The questions asked in the dairy were largely how

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

questions as Patton (2002) advised and, was followed by why questions to delve into deeper analysis about what they have experienced. The questions were related to the place and date of travel, mode of booking airline tickets, motives behind booking the tickets and the overall personal experiences behind the booking process similar. The researcher then read and analyses the complete textual data in the logs of the diaries. The respondents completed the diaries for all their ticket purchases and could mention any category without restriction as part of this exploratory approach. We requested the respondents record their ticket booking experiences for the next one month. The travels could be for any reason, whether business or personal. A discount coupon of 500 INR was given to the respondents as a token of gratitude for participating in the study. The questions provided to the respondents were semi-structured to meet the research objectives and were sufficiently general to elicit a broad spectrum of insights into the entire domain of e-ticketing. Basically, questions were largely how questions as Zeba et al. (2019) advised and, was followed by why questions to delve into deductive inferences about what they have experienced. The questions were related to the place of travel, mode of booking tickets, and personal experience and motives in the booking process.

To bring the validity and deeper understanding of the framework for reliability and validity was based on work by Whittemore, Chase, and Mandle (2001). The reliability of the findings of the present study was strengthened by documenting the stages of analysis. Further, an agreement between four coders and two experts about data interpretation has also been sought. For this four coders (including the two researchers) independently explored the themes. Then the themes identified by these independent coders were compared and contrasted and finally, an agreement was reached on the themes by seeking the advice of two experts. These experts have rich domain expertise in prominent airline firms in India. Member check was also done to contribute to the validity of the findings. Please refer Table 1 and 2 for more details on the emerged themes.

Out of the 60 participants, 35 were males and 25 were females. Around 14 respondents were working in the senior level position, 29 were working in the middle-level positions, and 17 were in the executive levels. 22 respondents were having professional degrees such as MBA and CFA. Around 20 respondents were having experience more than 15 years. To maintain confidentiality only gender, hierarchical level, education, and work experience have been asked from the respondents to understand their demographic profile.

DATA ANALYSIS

The final and the most important phases of dairy research are the analysis and interpretation of the results obtained through the dairy method. Because the qualitative data collected from the diaries do not have any in-build structure. Therefore, the next step is to find out a way to manage the raw textual data. The analysis of such qualitative data and deriving patterns from large chunks of the textual data set was done using the inductive content analysis (Vaismoradi, Turunen, & Bondas, 2013). Inductive content analysis is a method that has been widely used in analyzing the qualitative data collected from the participant's experience documented in the form of diaries. It helps in classifying the textual data into more small and meaningful phrases. The textual data collected from the diaries were being coded following the procedure given by Elo and Kyngas (2008). Each diary was read several times to get the meaning as a whole by both the researchers individually. Subsequently, each dairy was re-read and the phrases related to hedonic and utilitarian motives regarding online ticketing context were highlighted.

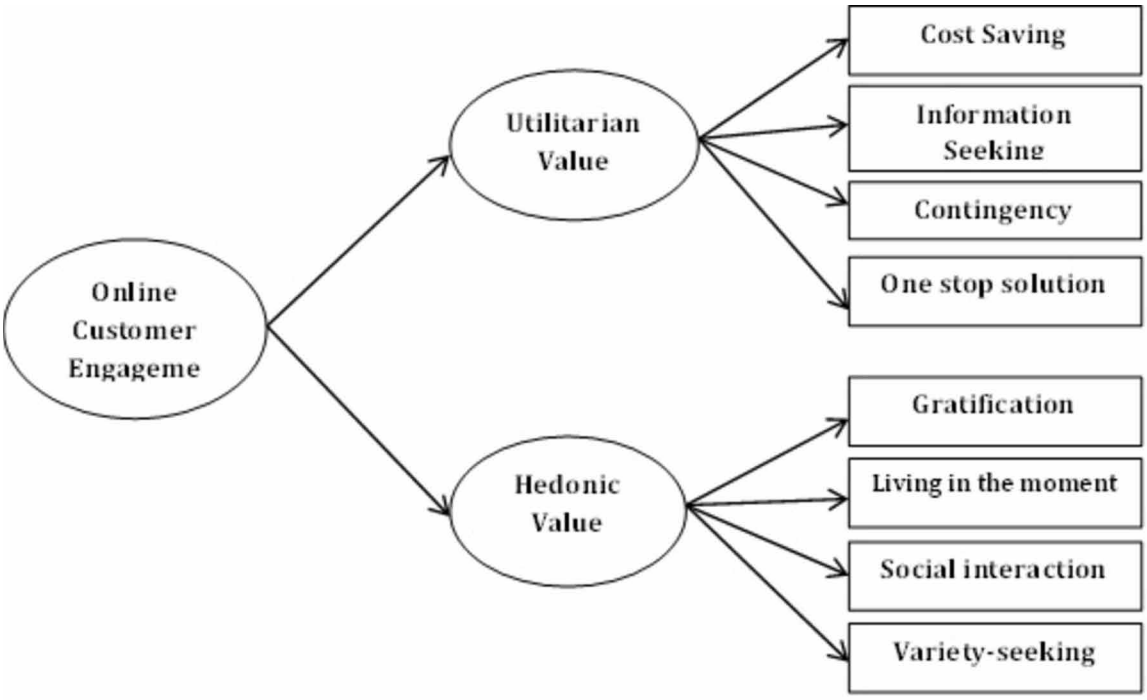
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

While reading, the codes relating to these highlighted texts were jotted down at the margins. Through the analysis, an attempt was made to have parsimonious codes, i.e., similar codes were combined together based on the hedonic and utilitarian motives behind air-ticket booking. After the open coding of three to four dairy logs, the preliminary codes were decided upon. The remaining content of the diaries were coded with these preliminary codes and new codes were added for the texts that did not fit into these existing codes. Once all the diaries were coded, data within a particular code were examined for consistency and relevancy. Further, these entries were exchanged and the codes were checked. Some codes were combined during this process, whereas others were splited into subcategories. Ultimately, the final codes were examined for organizing them into a hierarchical structure as possible.

FINDINGS

The exhaustive description given subsequently illustrates the themes that were identified from the inductive content analysis of the data. Eight major themes emerged for utilitarian and hedonic motivations behind the customer engagement towards online air-ticket bookings. The themes for utilitarian motivations are: (i) cost saving; (ii) information seeking; (iii) contingency; and (iv) one-stop solution; whereas themes for hedonic motivations are (i) gratification; (ii) living in the moment; (iii) social interaction; and (iv) variety-seeking. Please refer to Figure 1 for the conceptual model of online customer engagement.

Figure 1. Conceptual model



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Themes related to utilitarian value

Responses of the Participants	Codes	Themes
I get group discount which saves agent fees	Discounts	Cost Saving
Rewards points are accumulated in my e-wallet, which I can redeem in my subsequent bookings	Frequent flyer points	
I can check the list of agents and other travel houses which are co-partner with the site.	Different modes of payment	
I can compare the prices of different flights with airline websites and booking portals. Also, round trips, with/without hotel check-in and pick-up and drop	Comparing price	
Refund status can be checked, and complaints can be sent.	Quick Response	Information seeking
At times booking amount is deducted but the booking process is not complete. Even sometimes if I am stuck during online booking, I can avail the facility of online chat with the customer care to solve the queries	Query resolution	
Whether I have carried all the necessary items for the location I am travelling is suggested in web check in (id proofs, even warm clothes, extra luggage) or during travel insurance baggage	Travel tips	
Nowadays the portals are also saving my last searches and work as a reminder while going for booking	Recent Searches	
Last minute successful booking when the plan of the trip was sudden	Instant booking	Conditional Needs
Sometimes had to go for emergency trip (such as sudden demise or family emergency)	Emergency	
Whenever I want, I can go online and book. Like suddenly I want to attend a birthday bash of a friend I can book my tickets even in odd hours, such as 9 pm…. I can book and reach by 12 pm to wish her	Wee hours	
Now I can have booked or track my flights or PNR status through mobile apps or SMS too.	Convenience	
Suddenly, I came to know that my luggage is excess and exceeding the allowed limit, I converted the excess luggage in a parcel package which was delivered at the same time when I landed.	Excess Baggage	
I can book for both flights and hotels. Even the cab for pick-up and drop to the airport. It is soooo…. easy.	Cross selling	One stop solution
I can cross check my bank accounts simultaneously and I am saved from hunting the nearby ATM. Rescheduling and cancellations are easy online.	Links to other portals	
It's easier to chalk out a multi-routes flights journey. In this shuttling, I get 2-3 hours halt in a city and so get off to explore it and then can proceed for my journey to hometown.	Multi-route planning	
I am comfortable with the easy navigation and options of making my trip and don't want to check the other websites with which I'm not accustomed.	Ease of use	
Sometimes to reach to my destination I had to take multi-mode of transport, hence I can book flights, trains, bus etc from one site and no need to move to different sites for the booking.	Multi-mode travel	

Theme 1: "Cost Saving"

To et al. (2007) empirically showed that 'cost saving' is significant to utilitarian motivations. It is because online retailers have an edge over traditional brick and mortar retailers wherein their cost of production is lesser in terms of cost of rent, store installation, decoration, and personnel (Miller, 2000). This enables retailers to pass on the cost advantage to consumers, which keeps them engaged in online purchase behavior. Customers are engaged through various benefits associated with the cost factor such

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

as they can avail the cost advantage in online air-ticket booking through membership of the online ticket booking portals while traveling with family and friends. This also enables them to accumulate reward points. These points can easily be redeemed, which provide them with further price discounts. Various payment modes like credit card, net-banking, debit card, PayPal and other e-wallets give them liquidity and discounts as per their convenience. They can also compare the prices of different flights on the airline websites and other booking portals. Round trip bookings also give them added discounts.

I get group discount which saves agent fees. (Participant 1, male 30 years)

I can compare the prices of different flights with airline websites and booking portals. Also, round trips, with/without hotel check-in and pick-up and drop. (Participant 2, female, 42 years)

Table 2. Themes related to hedonic value

Responses of the Participants	Codes	Themes
While booking I can even book a cake, or gift which will be delivered at the preferred timing when I meet my spouse on our anniversary.	Simultaneous booking	Gratification
I do web check in when I am not carrying much luggage to avoid the queue for the boarding pass and proceed for the security check directly.	Customized Service	
Personalized account login option helps me in easy cancellation, provides alerts for flights 2-3 days before the scheduled dates	Personalized account	
One day my booking fails as their server was down they call back help me in completing my booking.	Augmented service	
My spouse is leaving in another city and I do not want waste the surprise break from the office. These portals are quite helpful me in planning family weekend getaway.	Getaway	
I can explore and take my own time for the different options without any rush and nag from the other people in the queue behind me… I am booking through a window. I like my privacy.	Ongoing search	Living in the moment
The personalised pages of these airline booking portals on Facebook, Twitter or other social networks, keeps me updated on the various offers and all I have to do is to like these pages.	Social Networking Experience	
I can even have the tour packages of holiday locations of the unknown country, festivals and even seasonal offers.	New experiences	
Safety of my luggage and kids by having a travelling insurance	Role shopping	Social Interaction
I can plan my travel virtually connected with my spouse/parents on the phone, video chat. As we all are able to browse the same website simultaneously	Simultaneously accessing the portal	
I can choose destinations simultaneously with my friends who stay in different parts of the world	Need for affiliation	
I seek opinion about my friends in FB to suggest on the latest deals and packages on various online portals	Interacting on social networking sites	
While booking my tickets I can choose my favourite cuisine on the flight.	Choice	Variety-seeking
These portals are quite handy when it comes to choosing my preferred seats. As I like window seats and my wife insists on seats near the emergency gate or near the exit.	Preference	
I explore several websites to get the best deal.	Bargain hunting	
Holiday Packages, Hotel Deals, other travel combo offers	Deals and offers	
I like adventure trips and these portals have some amazing ads to some of the most exotic locations in the world	Sensation	

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Theme 2: "Information Seeking"

Several studies have stated that 'information seeking' has a significant effect on utilitarian motivations. The internet is one of the most effective medium for seeking information about product specifications, details of stores, various promotions and so on (Wu, Wang, Wei, & Yeh, 2015; Wolfinbarger & Gilly, 2001). Information seeking is one of the important utilitarian values, which engages the customer in checking varied form of information related to online purchase cycle (Wu et al., 2015). For instance, we found that participants can check the status of their refunds and complaints easily from their login account any time. However, sometimes though the booking amount is deducted, the booking process is not completed. Refund details or status gets reflected in the personal login accounts, which can be easily retrieved and enquired by engaging in the online chat with customer care executives of these online portals. Certain airline websites even remind their customers to keep their passport, the requisite currency of that place, clothes pertinent to the weather, and to be aware of not exceeding the baggage limit prior to their travel; this keeps the customers connected even before experiencing the actual travel. Website visits enable the retailers to record the browsers' activity of their customers such as clicking particular buttons, logging in, or recording pages they have visited and the personal information filled by them. These act as a useful tool in engaging these customers in their subsequent visits to the portal. These portals also save their time, as the account history precludes them from re-typing their details again. For instant getaways with their spouse and family, they can book their tickets easily online.

At times booking amount is deducted but the booking process is not complete. Even sometimes if I am stuck during online booking, I can avail the facility of an online chat with the customer care to solve the queries. (Participant 5, male, 47 years)

Nowadays the portals are also saving my last searches and work as a reminder while going for booking. (Participant 15, female, 33 years)

Theme 3: "Contingency"

Contingency is a utilitarian motive in which consumers use heuristics to accomplish their purchases during an emergency (Baron, 1993; Hoffman & Novak, 1996). Consumers have a different set of engagement patterns with the online air-ticket portal, which is contingent on the situational requirements. For instance, we found that the participants encounter several emergency or urgent situations, which arose out of a sudden demise of a family member; attending celebration of friends or giving a surprise visit to their spouse. In these urgent situations, they need to book their tickets even at odd hours. These portals help them in booking at the time of emergency and contingent needs, as they operate throughout the day. Sometimes in the middle of the night, travelers find that their luggage has exceeded the allowed limit, and these portals enable them in converting their luggage into parcel bookings. These last-minute solutions turn out to be helpful to them, which keep them satisfied and connected with the web portals.

Whenever I want I can go online and book. Like suddenly I want to attend a birthday bash of a friend I can book my tickets even in odd hours, such as 9 pm I can book and reach by 12 pm to wish her. (Participant 26, male, 35 years)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Suddenly I came to know that my luggage is excess and exceeding the allowed limit, I converted the excess luggage in a parcel package which was delivered at the same time when I landed. (Participant 42, female, 50 years)

Theme 4: "One Stop Solution"

Compared to the traditional stores, online stores have more diversified offerings at a lower cost, as they do not have inventory pressures like physical stores and can afford to stock even less-popular products for niche markets (Alba et. al., 1997; To et. al., 2007; Wolfinbarger & Gilly, 2001). We found that our participants found these air-ticketing portals as 'one-stop solutions' for all their needs They were engaged with these portals in booking hotels and cabs along with their tickets from the same air-ticket booking portal because they found these portals to be more trustworthy and authentic, as during ticket booking they can simultaneously view their bank balance. They also book multi-route flights from these portals. They pointed out that often in international travel; there is a long halt between the two connecting flights. The online portals aid in seeing the halt time while they are chalking their multi-route itinerary. This enables them to effectively utilize this halt time in activities like catching up with friends in those cities, which keeps them hooked up with the portals for their future bookings. These portals also provide consumers in selecting different modes of transport, i.e., the portal not only inform them about no direct flight but also notify them about other alternatives like bus or cab or even train to reach their destination. Online portals make the re-scheduling and cancellation hassle free.

I can book for both flights and hotels, even the cab for pick-up and drop to the airport. It is soooo…. easy.(Participant 21, female, 36 years)

It's easier to chalk out a multi-routes flights journey. In this shuttling, I get 2-3 hours halt in a city and so get off to explore it and then can proceed for my journey to hometown."(Participant 48, male, 28 years)

Sometimes to reach to my destination I had to take multi-mode of transport, hence I can book flights, trains, bus etc from one site and no need to move to different sites for the booking. (Participant 39, female, 32 years)

Theme 5: "Gratification"

Arnold and Reynolds (2003) described this hedonic motivation as 'shopping for stress relief, shopping to alleviate a negative mood, and shopping as a special treat to oneself'. This type of hedonic motivation is rooted in McGuire's (1974) tension-reduction strategies. In this study, we found that customers are actively engaged with the portals for pre-booking gifts and flowers for their friends along with their flight bookings so that gifts reach their friends at the same moment in which they reach their friend's place. This brings in the surprise element in their meeting, which generates a feeling of gratification for the ease of booking gifts with the help of the portal. Similarly, participants reported that availing web checking services allow them to avoid the last minute rush at the boarding pass counter, and they can move to security check effortlessly. These portals also give personalized account and login access through which they can refer to their last booking history, enjoy the reward points, and feel emotion-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ally connected for the same. Further, the personalized account enables the consumers to receive alerts through mail or messages, which act as a personal assistant.

While booking I can even book a cake, or gift which will be delivered at the preferred timing when I meet my spouse on our anniversary. (Participant 33, male, 36 years)

I do web check in when I am not carrying much luggage to avoid the queue for the boarding pass and proceed for the security check directly. (Participant 42, female, 28 years)

My spouse is leaving in another city and I do not want to waste the surprise break from the office. These portals are quite helpful me in planning m family weekend getaway. (Participant 52, male, 37 years)

Theme 6: "Living in the Moment"

Babin et al. (1994) showed that consumers derive value not just from product acquisition but also from the complete shopping experience. This experiential hedonic motivation in engaging the customers (Thakur, 2016) was also found in the air- ticket booking, wherein consumers have displayed their preference for booking tickets in their desirable time, as they do not like the interruption of the fellow travelers in the conventional queue system of the window booking. In our study, participants were found to book their tickets and plan their travel at their own pace without any rush and hurry through an online portal. It is because they want to book tickets from their comfort havens, which also save them from the unpleasant experiences of traffic jams, limited parking, and long queue at the physical booking counters. Most of the websites have increased the standards of their sites aesthetics to entice and engage these types of experiential seeking customers (Thakur, 2016). Portals further aid them in selecting from various holiday locations to the unknown tourist places, unique festivals, and exotic seasonal offers, which pop-up advertisements display during the online ticket booking. Social networking sites enhance online ticket booking experience. Moreover, the participants are constantly updated and connected with the portals from which they become aware of various promotional offers.

I can explore and take my own time for the different options without any rush and nag from the other people in the queue behind me I am booking through a window. I like my privacy. (Participant 23, male, 31 years)

I can even have the tour packages of holiday locations of the unknown country, festivals and even seasonal offers. (Participant 48, female, 32 years)

Theme 7: "Social Interaction"

Social interaction is usually the main reason that motivates people to go shopping (Dawson, Bloch, & Ridgway, 1990). Social interaction has shifted from friends and relatives to interaction with virtual communities (Wolfinbarger & Gilly, 2001). Online shoppers share information and shopping experiences with people who share the same interest and remain engaged with the booking portals for their purchases (To et al., 2007). The role shopping is one of the kinds of social interaction and was evident in the study from the purchase of travel insurance by parents for their kids. These travel insurances like the one for

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

students going for studies abroad is a big solace for parents, as they are assured about the safety of their child. Other instances are the travel insurance for the minor kids traveling alone because it becomes the obligation of the airline authority and insurance company to ensure that the child reaches the destination safely. Participants also share the joy of browsing the same booking portal simultaneously by two people and jointly chalking out their travel plans even if they are located in different time zones. They are also increasingly converting their business trips into pleasure trips like catching up with friends and family. In these cases, the online portal acts as a handy tool that engages them in deciding on the places to visit as well as book the tickets immediately. Word-of-mouth in social networking sites like Facebook is instrumental in engaging through opinion building about these commercial pages of airline websites and booking portals. Customers can engage them by liking these pages to get the latest deals, offers, and other related promotions as Facebook notifications.

I can plan my travel virtually connected with my spouse/parents on the phone, video chat. As we all are able to browse the same website simultaneously. (Participant 44, male, 40 years)

I seek an opinion about my friends in FB to suggest on the latest deals and packages on various online portals. (Participant 55, female, 29 years)

Theme 8: "Variety-Seeking"

The hedonic motivation can be understood from the phenomenological study of Fischer and Arnold (1990), wherein consumers have confessed that they are like a 'kid in a candy store', who expresses excitement, heightened arousal, and a deep sense of enjoyment in shopping for variety (Kahn, 1995). In this study, variety-seeking has been displayed in the selection of favorite seats near the window or emergency gate through the online portals. Panoramic views prompt and engage the customers in choosing their favourite window seats. We found that preferred seats give them privacy with their loved ones and allow in meeting the various needs of their family members. These portals are also proliferated with customized solutions that engage customers by enhancing their choice selection like selecting cuisines from continental to Indian. Participants who are food lovers reported that they take this opportunity to choose their favorite cuisine available on the menu, which makes their journey memorable, as they experienced the world class dining amidst the floating clouds. It has also been seen that customers extensively explore several websites and portals until they zero down on their travel itineraries. Airline ticketing portal also gives the hotel packages at attractive rates. We found that the participants were attracted to the images of the exotic locations advertized on these portals, which trigger the impulsivity among adventure seeking customers to be impulsively attached to the portals.

"While booking my tickets I can choose my favorite cuisine on the flight." (Participant 59, female, 44 years)

"These portals are quite handy when it comes to choosing my preferred seats. As I like window seats and my wife insists on seats near the emergency gate or near the exit." (Participant 60, male, 55 years)

"I explore several websites to get the best deal." (Participant 47, male, 35 years)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

DISCUSSION

The online shopping of consumers is driven by certain motives that can be utilitarian or hedonic or both (Anderson et al., 2016; Babin et al., 1994; Childers et al., 2001). In a recent study on online shopping context, researchers like Thakur (2016) suggested that consumer's hedonic and utilitarian experiences engages the consumer in an online shopping context. Therefore, we extended the conceptualization of customer engagement by exploring the factors that explain the hedonic and utilitarian motives behind airline e-ticket purchase. These factors are explored from the emic perspective of online air-ticket booking consumers in the emerging markets like India. Emic perspective is captured through a diary method, which allows consumers to record their lived experiences in an uncontrolled setting.

In line with Bordie et al. (2013), we provided a holistic conceptualization of online customer engagement, as this holistic conceptualization depicts that consumers hold different expectations and have varied desires behind the purchase of airline e-ticket. Particularly, the conceptualization shows that the customer engagement is a function of experiential values that vary from one person to the other. Hence, the current qualitative investigation conceptualized customer engagement as the third order construct with hedonic and utilitarian as the second-order dimensions having four sub-dimensions each. The themes for utilitarian motivations are (i) cost saving; (ii) information seeking; (iii) contingency; and (iv) one-stop solution; whereas the themes for hedonic motivations are (i) gratification; (ii) living in the moment; (iii) social interaction; and (iv) variety-seeking. Further, the conceptualization of customer engagement in the context of online air-ticket booking is an under-explored area (Ruiz-Mafe, Sanz-Blas, & Aldás-Manzano, 2009; Mohseni, Jayashree, Rezaei, Kasim, & Okumus, 2018). Besides the validation of existing models like technology acceptance model (TAM) in online airline ticket booking (Davis, 1989; Chiu et al., 2009), limited studies have qualitatively understood the specific aspects behind customer engagement. Sheth et al. (1991) suggested that in a utilitarian product/service context, the choice of consumers could be driven not only by utilitarian values but also by hedonic values, as both are equally important. Finn (2005) empirically validated this argument and showed that feelings and emotions of the consumers are apparent not only in the entertainment services (hedonic) but also in the mundane visits (utilitarian) to consumer websites such as online air-ticket booking website. The present study is one of the few studies that enrich the contributions of Sheth et al. (1991) and Finn (2005) by proving an in-depth exploration of different aspects of hedonic values along with utilitarian values in the utilitarian service context of airline ticket purchase through the lived experience of consumers in the emerging market. Hedonic values were displayed in the role shopping (shopping for travel insurance and tickets booked online for loved and dear ones), booking tickets simultaneously from different time zones in virtual world, buying tickets and checking other complementary things at the same go (buying gifts by simultaneously browsing), variety-seeking (arousal) in seats, and food selection through online portal. Hedonic values associated with online airline ticket booking were also invariably linked to social networking sites (bargain hunting and patronizing the sites on these social networking sites). Ruiz-Mafe et al. (2009) examined the drivers and barriers to online airline e-ticketing purchase from the perspective of website design and features, but they did not discuss about any specific values of the consumer engagement derived from the e-ticketing purchase behaviors. Therefore, our study suggested different aspects of hedonic and utilitarian values behind engagement toward air-ticketing purchase. Similarly, Mohseni et al. (2018) through an empirical analysis confirmed that users' characteristics and website characteristics have causal effect on online travel purchase. Nevertheless, they have studied the personality traits of online users and not their cognitive and affective desires and values behind engagement toward the purchase of air-tickets. Our study

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

further added to the findings of Mohseni et al. (2018) by suggesting specific experiential values behind the hedonic and utilitarian values of online customer engagement.

Lastly, the novel way of capturing the real-time online experiences of the consumer of these airline booking portals through the diary method is another contribution of the study. Other qualitative techniques are based on experiences and recall, which might result in forgetfulness as well as articulation (Jadhav & Khanna, 2016; Ozkara, Ozmen, & Kim, 2017). The personal diary technique gives respondents control and they can account for their experiences freely in their own way. The self-completion diary method employed allows us to capture and interpret the emic perspective through the lived experiences of the consumers behind air-ticket purchasing in a meaningful way.

MANAGERIAL IMPLICATIONS

One of the implications of these findings is that like utilitarian values, hedonic experiential values should be equally given importance (Sheth et al., 1991) by considering them while designing the airline ticket booking portals to engage the customers. It should be noted that Indian consumers have reached a certain level of technology readiness; and hence, they want something beyond the usability and functional aspects of the booking portals, which can keep them attached and connected. Thus, utilitarian benefits can be considered as the basic core services. However, in order to stay ahead of the competition, it is critical for service provider to engage the consumers, so they should enhance their service offerings by including hedonic benefits as well. Hence, this study is very useful in terms of explaining the thoughts and believes of Indian air-ticket booking consumers about hedonic and utilitarian benefits. Apart from elaborating the marketers' perspective on these two types of values, this study is equally relevant to website design domain, i.e., the way websites should be designed to induce customer engagement by enhancing its quality and aesthetic appeal through the incorporations of cues and tailor-made around the sub-dimensions of hedonic and utilitarian values. Another implication of this study lies in the awareness and need for collaborating with other service providers' portals with the airline ticket booking portal. Consumers are constant bargain hunters and can be engaged and hooked to a portal that has all the links that fulfill their buying needs (from just buying a ticket to other complementary needs like car rental, hotel booking, and travel insurance). Lastly, this study has also revealed the importance of social networking sites in infusing the tendency of bargain hunting and patronizing the booking sites integrated with the social networking sites.

LIMITATIONS AND FUTURE RESEARCH

The sample of the present study includes online air ticket booking consumers only and does not capture the experiences of other potential online consumers who are frequent visitors of other portals like online book purchasing sites, online grocery portals and so forth. Future research can analyze the hedonic and utilitarian values of these potential customers from their lived experiences to enrich the domain of customer engagement in the online context. Future research can also empirically validate the conceptual model of the present study. Specifically, the third order factors of the two types of values can be used to design and develop an instrument for capturing online customer engagement. This study has taken online airline booking portal, which is viewed as more utilitarian than hedonic product or service. Thus,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

a comparative study should be undertaken by considering other portals with this online airline ticket booking, which are more of hedonic than utilitarian such as fashion apparel portals. Future research can also have dyadic perspective behind include marketer's (e.g., experts and consultants, management, website designer and travel agent) perspective as well as to understand online customer engagement. The importance of interactive social networking in fostering the business of these online booking portals can also be explored. Information system research should be done to enhance the website quality and aesthetics like the incorporation of links and innovative clicking techniques. The study can also analyze the account of the customer complaining about service failure (time involved in a search of the best deal, and technical problems like payment gateway, disconnection in the middle of the transaction). Thus, future research can examine the determinants of these service failures and their hindrance in customer engagement with the online portals.

Chapter 65
Men vs. Women:
Study of Online Shopping Habits and Factors Influencing Buying Decisions in Bahrain

ABSTRACT

The purpose of this article is to measure the difference between Bahraini men and women in terms of their habits of online shopping and determine factors affecting their buying decision. The researchers adopted a technology acceptance model (TAM) as a research conceptual framework. A questionnaire was developed and distributed randomly to a sample of Bahrainis. Collected data was analyzed to test the research framework and hypotheses using multiple regression analysis. Results show there is a difference between men and women in term of trust, habit, satisfaction, perceived ease of use, and risk. The limitation of research stems from the majority of the participants aged between 18-28 years old, which could not represent all population age group. The article identifies key predictors of the online buying decision, enabling entrepreneurs and practitioners of online business to understand which factors will be useful to draw a rigid strategy for their online presence. Previous studies on online shopping did not give much concern to gender factor, while the current study investigates differences between men and women online shopping habits and reaching new facts about factors that influence the Bahraini buying decisions.

INTRODUCTION

Online shopping is the process of purchasing products or accessing services through internet network, whit the broad scope of products and services available to consumers all around the world. Increasing use of online shopping has become a threat to the traditional shopping (Masoud, 2013). With online shopping, it became easier to get the desired items in different markets rather than the national one.

Online shopping is a process taken by customers of browsing and/or buying products or services by using online shops or social media, in a comfortable way at their home (Roblek et al., 2013; Jusoh and Ling, 2012). Nowadays online shopping grows to be the most popular shopping style for customers because the Internet becomes widespread dramatically (Lin, 2013). Online shopping makes shopping easier, it allows customers to choose and compare the price of product between different sellers and choose the best, so the decisions of buying can be made at home in an easier way (Ali and Sankaran, 2010).

Numerous research indicates that there is significant difference of online behavior according to gender. Hernández et al. (2011) conducted a study on age, gender and income and their impact to online shopping behavior, and revealed significant differences between men and women in their behavior. Another study conducted by Hansen and Jensen (2009), about shopping orientation and online clothing purchases supported the conclusion of differences between gender in attitude toward the shopping and Intention buy the clothing via online. The females are most responsive to the presentations and advertising whether positive or negative, in this case, they are more displayed to shopping over the internet than males (Garbarino and Strahilevitz, 2004). In addition, there are differences between males and females in their association with technology (Slyke, Comunale and Belanger, 2002). A study conducted by Herter (2013) suggest that women demonstrate higher levels of shopping satisfaction, recommendation, return intentions and hedonic shopping than men.

The online shopping in Bahrain takes place among the majority of population members. Regardless of the age and interest, people start to use online shopping frequently, through both the website and social media (Crnkovic, 2013). However, the factors that affect online buying decision are not well studied from the Bahrain context. The goal of this research is to investigate the factors that affect online shopping habits in Bahrain with the focus to male and female buyers.

This study is organized in six research structures. The first section introduces the statement of the research problem that presents the argument, which tells what is the study about and stating the research questions that arises. The second section defines and analyzes the literature review related to the habits and factors influencing online shopping buying decision in the University of Bahrain and then highlights the theories researchers used in the current study. Section three describes the research methodology. The fourth section describes the analysis researchers used and tabulates all the data that have been collected. In section five, the main results of the survey questionnaires are discussed. Finally, the last section introduces the conclusion and recommendation for further research.

DETERMINANTS OF ONLINE SHOPPING

Technology Acceptance Model (TAM) has been developed from reasoned action theory and planned behavior theory (Ibrahim, 2013). TAM is used for researching the determinants of information technology for end-user behavior, but numerous researchers suggest that there are additional influence of external variables, besides the core theory variables: perceived ease of use and perceived usefulness, intention

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

to use and actual use behavior. In this paper, we develop the following TAM model in terms of adding new factors "Habit," "Trust," "Risk," "Satisfaction" and "Security." The elements of the model will be elaborated in the following discussion.

Security

The increasing use of online shopping shows an increase of consumers' concerns in terms of security of online shopping (Gehrt et al., 2012). One of the factors, which cause consumers not to use online shopping, is security, if the consumers have concerns regarding the online shopping security. The consumers may avoid using online shopping for different reasons such as fear of credit card fraud, privacy and risks of not receiving goods and services at right time (Su and Huang, 2011). In order to protect the privacy of consumers through online shopping, security has to be established with the customers, mainly by the means of technology. There are many specialized companies to provide security for online shopping sites to protect them from unauthorized persons such as providing software to security (Liu et al., 2005; Gehrt et al., 2012). Therefore, based on this research we develop the following hypothesis:

H1: Security affects "Trust factor" of Make Buying Decision.

Trust

Trust is the most important factor in online shopping (Turkyilmaz et al., 2015). As it has been defined by Oxford dictionaries that Trust is a "Firm belief in the reliability, truth, or ability of someone or something: relations have to be built on trust, they have been able to win the trust of the others". It is usually known as a relationship factor based on experience (Kim, 2012). When the organization provides a security guarantee, the customer trust in the organization website may directly affect by customer trust in online shopping (Santos and Fernandes, 2011). According to Awad and Ragowsky (2008), there is a difference in trust between men and women in online shopping, and the trust affects the behaviour difference between man and woman. As a result, the trust is very important and plays a major role in the intention of online shopping for women more than for men. Therefore, based on this research we develop the following hypothesis:

H2: Trust factor affects "Intention" of Make Buying Decision.

Risk

Perceived risk is a factor that numerous authors studies in relation to the behavior of customer in online shopping (e.g. Mandilas et al., 2013). Perceived risk is one of the factors that affect consumers' decision-making in online shopping. In addition, perceived risk has an important role in consumers' behavior. Many studies about perceived risk in online shopping showed that perceived risk have a negative effect (Masoud, 2013). However, male and female have different expectations on perceived risks of online shopping. Based on Garbarino and Strahilevitz (2004) study on how the perceived risks effects on gender in decisions purchased, suggests that there are differences between the genders in the impact of the factor perceived risks on the decisions purchasing. As a result, they found that women are considering online shopping risks more than men are. Therefore, based on this research we develop the following hypothesis:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H3: Risk affects "Trust factor" of Make Buying Decision.

Habit

According to Hsu et al., (2015), the habit is defined as action performed frequently or reaction automatically resulting of previous experience. Habits are also used to forecast the behavior of customers in traditional retail but habits of customers in online shopping are more complex due to the increased risk and uncertainty. Habit has relation with other factors that may affect the intention of purchase such as a trust, e.g. sometimes habits have negative impact on the relationship between trust and purchase intention (Chiu et al., 2012). Therefore, based on this research we develop the following hypothesis:

H4: Habit affects "Trust factor" of Make Buying Decision.
H5: Habit affects "Perceived ease of use" of Make Buying Decision.
H6: Habit affects "Perceived usefulness" of Make Buying Decision.

Satisfaction

Customer satisfaction is an emotional reaction and it comes from the cognition from buying process to after buying. Mostly, customer satisfaction is related to factors such as price, product quality, the photo of the product, consistency of products and site design. Turkyilmaz et al., (2015), Gehrt, et. al., (2012) and Pabalkar, (2014) points out that website quality is very important for consumers' online buying, directly affecting satisfaction. The customer satisfaction is the comparison between expectation and conception of a product. For example, the customers often worry that the real products are different from the photos of the website (Lin, 2013). In reality, the product uncertainty takes the main role in online customer satisfaction. Thus, it is found that the high product uncertainty and low retailer visibility reduce customer satisfaction, and the pricing, customer service, and website design have a direct effect on customer satisfaction (Luo, Ba and Zhang, 2012). Therefore, based on this research we develop the following hypothesis:

H7: Satisfaction affects "Intention" of Make Buying Decision.

Intention

The intention is affected and formed by two variables, which are Perceived ease of use and usefulness, and then intention effect on the actual behavior (Renny et al., 2013; Mandilas et al., 2013). Yulihasri et al. (2011) said that the Perceived ease of use and usefulness are silent beliefs and they have a high significance in affecting the intention of online shopping. According to Halim et al. (2005), the relationship between satisfaction and buying intention is very strong. Therefore, based on this research we develop the following hypothesis:

H8: Perceived usefulness affects "Intention" of Make Buying Decision.
H9: Perceived ease of use affects "Intention" of Make Buying Decision.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Buying Decision

The buying decision is an actual behavior. The actual behavior can be taken by individuals to do something. Jeddi et al. (2013), said there are processes to make the decisions which are: Identify the problem, Search for information, Evaluation of Options, Purchase, after purchasing behavior. Buying decision is affected by other variables and it has a direct relation to the buying intention (Renny et al., 2013). Therefore, based on this research we develop the following hypothesis:

H10: Intention affects Make Buying Decision.

Perceived Usefulness

Usefulness is related to time and effort saving and reducing the cost (Renny et al., 2013).

Studies about the perceived usefulness indicated that it has a stronger influence on usage (Ibrahim, 2013; Mandilas et al., 2013). Moreover, it is affected by external variables and shares in forming the intention, and it has a direct effect on intention. Therefore, based on this research we develop the following hypothesis:

H11: Perceived usefulness affects "Satisfaction factor" of Make Buying Decision.

Perceived Ease of Use

Perceived ease of use measures if the person can use and learn the systems in an easy way. Previous studies about the perceived ease of use indicated that it has a significant impact on intention either directly or indirectly across impact on perceived usefulness. However, it is affected by external variables and it contributes in forming the intention. Also, perceived ease of use has a direct effect on intention and it is related to the usability (Renny et al., 2013; Mandilas et al., 2013, Pabalkar, 2014). According to Turkyilmaz et al., (2015) and Gehrt, et. al., (2012) website ease of use and product availability are important precursors of online buying. Therefore, based on this research we develop the following hypothesis:

H12: Perceived ease of use affects "Satisfaction factor" of Make Buying Decision.

METHODOLOGY

A sample of respondents is selected from among the population of students in the University of Bahrain. The questionnaire administered online using Google Form and the link was distributed by email and social application (WhatsApp) among students. Also, a hardcopy of the questionnaire was distributed randomly among citizen. The number of participants of the online questionnaire was 251 and the number of participants in hardcopy questionnaire was 201, so the total number of participants was 452. The data was collected in ten days, from 6th to 15th of April 2015.

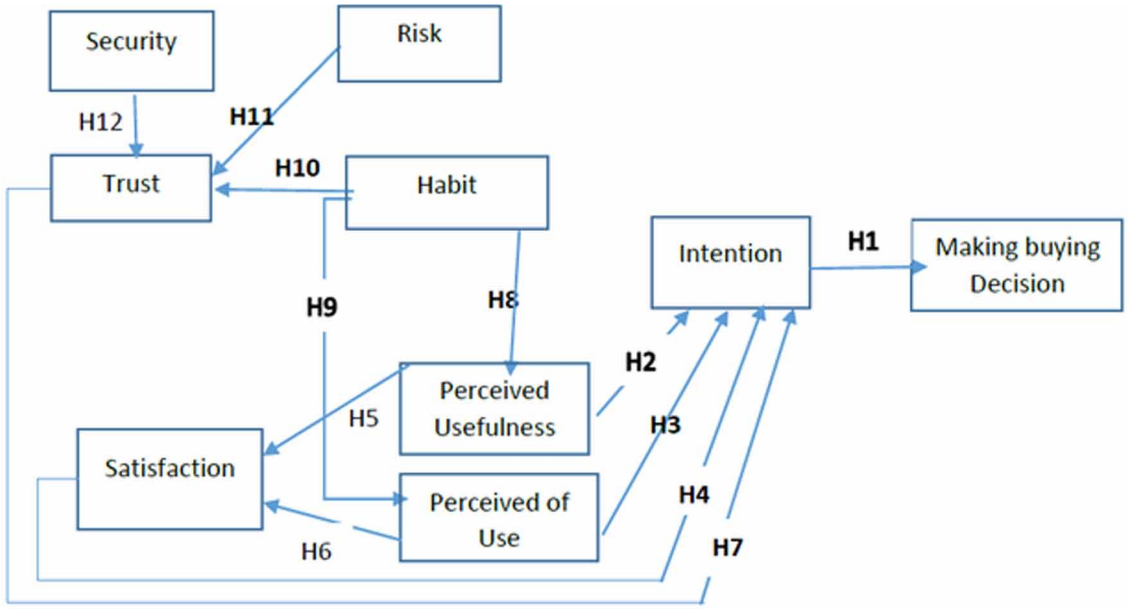
A structured questionnaire was used as a study tool (see Appendix). It consisted of two sections: the first section collected demographic data relevant for this study, and the second section consisted of the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

research questions that measure the online shopping use, habits and the factors affecting on the buying decision. Questions all are closed-ended questions providing multiple options to choose from a Likert scale.

The personal data and project questions from the questionnaire were analyzed using the Statistical Package for Social Science (SPSS). The response of the participant was presented in percentages. Answers were classified accordingly into the use of online shopping, men and women habits and the affecting of factors in the buying decision among Bahraini citizens. Multiple regression was used for testing the hypothesis of the research model. Figure 1 shows the proposed framework of the hypothesis.

Figure 1. The proposed framework



Results

Majority of the respondents are between the age of 18 and 28 (73.7%), and the oldest respondents are aged 49 years old or more (2.7%). More than a half of respondents are female (51.1%), while 48.9% are male. Half of the respondents have an educational background of bachelor's degree (50.2%), and 8.8% respondents come from a postgraduate education background. There are 28.1% respondents from high school, while 12.8% has diploma certificate. Most of the sample are students (56.4%), while there are the smallest number of retirees (2.7%). Government-employed represents 25%, the self-employed represents only 4.6% of the sample, while unemployed represents 11.3% of the sample. Most of the respondents use online shopping occasionally (55.3%), e.g. when there would be a big web sale or give away large discounts and coupons, while the lowest number of respondents are those that use it weekly (4.6%). 25.2% of the respondents use online shopping monthly, while 14.8% never used online shopping. Usually, items that are highly purchased online are clothes (41.5%), and the smallest number of respondents are buying food online (6.4%). 33.8% of respondents purchased accessories and 25.9% purchased electronics via online

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

shopping, while 14.8% of respondents purchased other products. Amazon is the most popular website to shop online (48.9% respondents), whereas only 2.7% respondents use Home Site which makes it the lowest choice to shop online. 30.1% of respondents buy from eBay, 11.7% from Booking, 8.6% from Alibaba, 5.1% shop from Flipkart, and 17.5% shop from others online shopping sites.

Table 1 shows results of factor analysis, where the buying intention, perceived usefulness, perceived ease of use, routine habit, purposeful habit, trust, security, satisfaction and risk that have score of alpha equal or over 0.7, meaning that the reliability is acceptable. However, buying decision has a Cronbach's alpha slightly lower than 0.7 but is still in the 0.6 area, which makes it acceptable according to Nunnally and Bernstein (1994). The Factor Analysis is used to reduce the number of large items in factor to smaller number of items for each factor by combining a set of related items into one comprehensive variable. These items are represented in following codes: BD = Buying Decision; BI = Buying Intention; PU = Perceived usefulness; PEU = Perceived ease of use; HABIT = Habit; TRU = Trust; SAT= Satisfaction; and SEC = Security. Two factors related to habit are identified: routine habit and purposeful habit.

Table 1. Factor analysis and Cronbach's Alpha

Component	Items	Factor Analysis	Cronbach's Alpha
Buying Decision	BD1	.646	.615
	BD2	.731

Table 2 shows the result of the cross-tabulation of all categories maturity level to differentiate men and women online shopping habits and factors influencing their buying decision. Three levels of average values of factors were defined: low, medium, and high. Results indicate that there are not significant differences between female and male according to different elements of research model.

Table 2. Differences between female and male

	Cases						
	Male				**Female**		
	Low (%)	**Medium (%)**	**High (%)**		**Low (%)**	**Medium (%)**	**High (%)**
Buying Decision	1.4	45.0	53.6		2.8	46.5	50.7
Buying Intention	0.5	29.4	70.1		2.8	25.1	72.0
Perceived Usefulness	2.4	37.1	60.5		0.9	32.3	66.8
Perceived Ease of Use	1.6	35.1	63.4		1.0	23.7	75.4
Routine Habit	7.6	66.5	25.9		12.3	58.8	28.9
Purposeful Habit	1.8	25.7	72.5		2.0	23.0	75.0
Trust	2.9	65.9	31.2		6.3	58.9	34.8
Security	17.7	56.5	25.8		17.8	57.9	24.4
Satisfaction	1.1	29.8	69.1		3.0	40.8	56.2
Risk	12.2	50.3	37.6		5.4	40.1	54.5

Source: Authors' work

Table 3 presents descriptive statistics for all factors and their correlations. Buying decision has a weak correlation with routine habit (19.1%) and security (26.6%). It has a moderate correlation with buying intention (42.7%), perceives usefulness (33.2%), perceived ease of use (30.4%), purposeful habit (44.5%), trust (34.2%) and satisfaction (42.9%). Buying intention has a weak correlation with routine habit (29.5%). It has a moderate correlation with perceives usefulness (42%), perceived ease of use (38.7%), purposeful habit (38.1%), trust (50.2%), security (32.4%) and satisfaction (44.4%). In addition, the perceived usefulness has a weak negative correlation only with risk (-2.6%), and moderate correlation with other factors. The perceived ease of use has a weak correlation with routine habit (17.9%) and purposeful habit (25.9%), and moderate correlation with trust (36.2%), security (32.1%) and satisfaction (35.8%). On the other hand, the routine habit has a weak correlation with purposeful habit (26.9%), and moderate correlation with trust (55.9%), security (54.8%) and satisfaction (46.3%). However, the purposeful habit has a weak correlation with security (36.5%), and moderate correlation with trust (41%) and satisfaction (48.3%). The trust factor has a moderate correlation with security (63.8%) and satisfaction (59%). Lastly, there is a moderate correlation between security and satisfaction (53.2%). Not to forget, the risk factor has a weak correlation with all factors. Results indicate that there is no problem of correlation among the investigated variables.

Regression analysis was run on the factors received from factor analysis with the following results shown in Table 4. Summary results of hypothesis testing are presented in Table 5.

Note: DV-dependent variable, * statistically significant at 5%; ** 1%

Model 1 shows the regression analysis with the independent variables security, risk, purposeful habit, and routine habit against the dependent variable of trust. It was found that the coefficient beta for both male and female about security, routine habit and purposeful habit have positive relationships. The male has positive 51.9%, 24.9% and 18.2% beta percentage respectively, while the female has positive 44.1%, 44.4% and 10.4% beta percentage respectively. Thus, results indicate that H1 and H4 for both male and female are supported. There is an exception to risk even with low positive 1.5% beta percentage for male, while it still makes H3 unsupported along with a negative 3.5% beta percentage for the female, which is also insignificant.

Next, Model 2 run a regression between the independent variables routine habit and purposeful habit on the dependent variable perceived usefulness. The result for the coefficient beta explained that both male and female in routine habit and purposeful habit have a positive relationship. The male shows

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

28.1% and 18.7% beta percentage respectively, while female shows 45.4% and 31.8% beta percentage respectively. Hence, they are significant and for both male and female H6 are supported.

Model 3 presents the regression explaining the relationship between routine habit and purposeful habit against perceived ease of use, where the relationship result is the weakest for the male. It shows that routine habit for the female is significant with 18% beta percentage, is better than the male insignificant beta percentage of 12.9%. However, both male and female have positive 25.2% and 32.1% beta percentage on purposeful habit respectively. Thus, make the habit factor among the female buyers supports H5, while for male it is unsupported.

Besides that, Model 4 shows regression between independent variables of perceived usefulness and perceived ease of use against satisfaction as dependent variable. The coefficient beta of both male and female in perceived usefulness and perceived ease of use indicate a positive relationship. The male has positive 23.1% and 35.7% beta percentage respectively, while the female has positive 45.7% and 19.4% beta percentage respectively. This results in H11 and H12 being supported for both genders.

Model 5 present the relationship between perceived usefulness, perceived ease of use, trust, and satisfaction against buying intention. Here, the coefficient beta of the relationship for both male and female are explained as follows: The male perceived usefulness, perceived ease of use and trust all have a positive beta percentage of 22.3%, 20%, and 18.4% respectively, except satisfaction with an insignificant positive 13.6% beta percentage. Meanwhile, the female perceived usefulness, perceived ease of use and satisfaction all have a positive beta percentage of 33.8%, 15.4%, and 17.1% respectively, except trust with an insignificant positive 12.3% beta percentage. As a result, both male and female supports H8 and H9. However, H2 is supported by the male and unsupported by the female, while H7 is supported by the female and unsupported by the male.

Table 5. Overall hypotheses results

Statement of Hypothesis	Decision	
	Male	Female
H1: Security affects "Trust" of Buying Decision.	Supported	Supported
H2: Trust factor affects "Intention" of Make Buying Decision.	Supported	Unsupported
H3: Risk affects "Trust factor" of Make Buying Decision.	Unsupported	Unsupported
H4: Habit affects "Trust factor" of Make Buying Decision.	Supported	Supported
H5: Habit affects "Perceived ease of use" of Make Buying Decision.	Unsupported	Supported
H6: Habit affects "Perceived usefulness" of Make Buying Decision.	Supported	Supported
H7: Satisfaction affects "Intention" of Make Buying Decision.	Unsupported	Supported
H8: Perceived usefulness affects "Satisfaction factor" of Make Buying Decision.	Supported	Supported
H9: Perceived ease of use affects "Satisfaction factor" of Make Buying Decision.	Supported	Supported
H10: Intention affects Make Buying Decision.	Supported	Supported
H11: Perceived usefulness affects "Intention" of Make Buying Decision.	Supported	Supported
H12: Perceived ease of use affects "Intention" of Make Buying Decision.	Supported	Supported

Lastly, Model 6 shows the regression between the independent variables buying decision and the dependent variable buying intention. It shows the coefficient beta of the relationship for both male and female explained that Buying Intention has positive 32.5% and 59.4% beta percentage respectively. This makes Buying Intention significant, thus male and female H10 are supported.

CONCLUSION

The purpose of this research is to identify the difference between men and women according to their online behavior in Bahrain. Following differences were found: (i) there is a difference to the variable of perceived ease of use where women have higher rate than men; (ii) variable Satisfaction has the following difference with the men having a higher average value of Satisfaction compared to women; and (iii) variable Risk has higher value for women compared to men. Other variables did not reveal significant differences.

The Technology Acceptance Model (TAM) was used to determine the factors that affect the men and women behavior when shopping online. A modified version of the TAM model was constructed in order to investigate the impact of various factors to the online purchase. It was found that habit positively affects perceived usefulness and trust. In addition, perceived usefulness and perceived ease of use positively affects buying intention and satisfaction. Multiple regression analysis was used for testing the research model, indicating that online shopping is impacted by numerous factors. According to the variables that have been studied, this research concluded that there are differences between men and women in term of perceived ease of use, trust, habit, satisfaction, and risk when making decisions about online buying.

ABSTRACT

The emergence Web 2.0 technologies has transformed e-commerce into social commerce. The benefits associated with social commerce are well known. However, for businesses to reap such benefits, the factors that influence user intention to use social commerce must be understood. However, existing studies draw samples from developed countries. Given that geography and cultural factors affect technology adoption, findings from existing studies may not apply in the developing country context. This study therefore investigates the factors that influence user intention to use social commerce in developing countries. A survey questionnaire was used to gathered responses from 614 students in Ghanaian universities and analyzed using PLS-SEM. The results indicate that information quality, system quality, and service quality have significant influence on user intention to use social commerce. The findings point out the need to provide relevant support to users and ensure accurate and reliable information on social commerce platforms.

INTRODUCTION

The emergence of new Web 2.0 technologies has transformed many aspects of our society. The pervasiveness and ubiquitous use of Social Networking Sites (SNSs) have been the main driver of this transformation. SNSs enable cost-effective yet efficient ways for online interaction and communication. This has evolved traditional e-commerce into social commerce (Hajli, 2015). Social commerce is a new e-commerce development that enables the use of Web 2.0 technologies to support online interactions where the contributions of people can be used in the acquisition of goods and services (Liang and Turban, 2011). It has transformed consumers from passive receivers to co-creators (Hajli and Sims, 2015). Indeed, social commerce was found to have increased sales from 5 billion dollars to 15 billion dollars in 2014 (Morrison, 2014). Thus, the significance of social commerce cannot be undermined.

Yet, social commerce research is scarce in Africa. Many of the existing studies on social commerce drew samples from developing countries. However, socio-cultural characteristics affect technology adoption and use (Apau, Koranteng and Adu, 2019). Since developed countries possess different characteristics compared to developing countries, existing findings may not be applicable (Wiafe et al., 2019). People in developing countries are hesitant to adopt new technologies. To add, many of these people lack the required skills to use ICT tools appropriately. Moreover, relevant research indicates that Web 2.0 technologies are widely regarded as entertainment tools (Koranteng, Wiafe & Kuada, 2019). This suggests that users may not perceive such tools as useful for commerce. Additionally, more research that delve into facet of consumer behavior in the digital economy is deemed necessary (Ling Chang, Ling Tam, & Suki, 2016; Nathan, Fook Chiun, & Suki, 2016; Suki, 2013a; 2013b; Suki, 2016; Suki & Abang Sulaiman, 2016). Therefore, there is the need to uncover which factors influence users in such areas to adopt social commerce.

This chapter, therefore, implements the Information Systems (IS) Success Model (DeLone and McLean, 2002) as a theoretical lens to understand the factors that affect users Intention to Use Social Commerce in developing countries. The next sections present a review of relevant literature and research methods. This is followed by a summary of the analysis. Then the results are discussed. Finally, conclusions and directions for future work are drawn.

LITERATURE REVIEW

The rise of Web 2.0 technologies has given birth to a new stream of e-commerce called social commerce. Social commerce is essentially the delivery of e-commerce via Social Networking Sites (SNSs) (Liang and Turban, 2011). This new technological advancement offers online shoppers the ability to interact with other shoppers and systems in profound ways such as sharing product experiences, recommendations, rating products and reviews (Hajli and Sims, 2015). Some scholars, however, believe that this has changed the structure of many business models. Nowadays, there is much focus on customer-oriented business (Zhang and Benyoucef, 2016) where marketing strategies have shifted from attracting customers' awareness of products to bonding with them after their purchases (Edelman, 2010).

For businesses to be able to harness the power of social commerce, factors that influence user behavior on these platforms must be understood. Consequently, a stream of researchers has explored user motives and behavior in social commerce context. Scholars have found that perceived effectiveness, entertainment, enjoyment, and information-seeking gratifications affects consumers' intention to adopt social

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

commerce (Davis, Piven, and Breazeale, 2014; Momani, Yafooz, and Jamous, 2018). Others have used behavioral theories such as Theory of Planned Behavior and Technology Acceptance Model to explain the important roles of perceived usefulness, ease of use and attitude in social commerce adoption and use (Chen, Hsiao, and Wu, 2018; Hansen, Saridakis, and Benson, 2018; Liu, Lu, and Yu, 2018). Meanwhile, social influence and social support have all been found to affect social commerce adoption (Hajli, 2014; Liang, Ho, Li, and Turban, 2011).

This suggests that prior research predominantly emphasized individual characteristics whilst ignoring the role of system characteristics in social commerce adoption. In addition, technology acceptance is influenced by geography. Indeed, user behavior on SNSs platform differs across cultures (Koranteng, Wiafe, Katsriku & Apau, 2019). Hofstede (2001) argued that people in many African countries are likely to reject new technology due to their cultural resistance to innovation. Koranteng et al., (2019) points out that, users in these areas perceive SNS tools as useful for entertainment, however, it is unlikely users will perceive them as effective for commerce. Given these, this chapter deviates from previous studies that focused primarily on individual characteristics in developed countries to understand social commerce adoption. It employs the IS Success Model to examine how the characteristics of a social commerce platform affect users' intention to use.

Theoretical Framework and Hypotheses Formulation

Many theories have been adopted to explain information systems acceptance and use. Technology Acceptance Model (Davis, 1989), Theory of Planned Behavior (Ajzen, 1991) and Unified Theory of Acceptance and Use of Technology (Venkatesh, Morris, Davis, and Davis, 2003) are among the most popular of these theories adopted. However, these theories are limited since they fail to consider essential factors such as the role of organizational support in influencing technology adoption. Meanwhile, the IS Success Model proposed by DeLone and McLean (2002) caters for this limitation. The IS Success Model argues that Use behavior or Intention to Use a particular technology is dependent on the three quality antecedents: Information Quality, System Quality and Service Quality. Information

Quality defines the quality of output generated by the social commerce platform. System Quality evaluates technical features such as reliability, responsiveness, and availability of the platform. Service Quality is concerned with the availability of competent technical support for users who use the social commerce platform. Whereas the theory also proposes that Use Behavior could also predict user satisfaction and other net benefits, this chapter focuses on the factors that affect users Intention to Use Social Commerce. Consequently, the effects of Information Quality, System Quality and Service Quality on users Intention to Use Social Commerce are examined. This approach has successfully been employed by several studies (Jagannathan, Balasubramanian, and Natarajan, 2018; Lwoga, 2014; Lwoga and Sife, 2018). Table 1 indicates a summary of the construct definitions and their sources from literature. Figure 1 also depicts the relationships between the constructs.

Information Quality (IQ)

Information Quality denotes the characteristics of the output generated by the social commerce platform (Lwoga, 2014). It measures the degree of relevance, accuracy, understandability, completeness, timeliness and usability of the information on these sites (DeLone and McLean, 2002). According to Jagannathan et al., (2018) users may adopt a system because it provides relevant and reliable information. This may

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

also affect their judgement of the systems' quality. Prior studies have found a significant relationship between Information Quality and Intention to use (Lwoga, 2014; Lwoga and Sife, 2018). It is therefore hypothesized that:

H_{1a}: Information Quality significantly affects Intention to Use social commerce.
H_{1b}: Information Quality significantly affects System Quality.

Table 1. Construct Definition

Construct	Definition	Source
Information Quality (IQ)	It defines the quality of output generated by the social commerce platform.	(Jagannathan et al., 2018)
Service Quality (SeQ)	It is concerned with the quality of the support that users receive from the social commerce platform support staff.	(DeLone and McLean, 2002)
System Quality (SQ)	It defines the usability features of a social commerce platform.	(Lwoga and Sife, 2018)
Intention to Use Social Commerce (INT)	It is the possibility that users will use the social commerce platform in the near future.	(Venkatesh et al., 2003)

Service Quality (SeQ)

Service Quality is the extent to which users perceive they get the required support they need. It is measured in terms of technical competence, empathy, reliability and responsiveness of the social commerce platform staff (DeLone and McLean, 2002). Efficient institutional support influence users' perception of the system's quality (Rana and Dwivedi, 2015). Thus, users are more likely to use social commerce when they perceived that the needed support is available. However, Lwoga and Sife (2018) found that Service Quality do not predict Use Behavior. It becomes important to confirm the effect of Service Quality on users Intention to Use Social Commerce in developing countries. It is therefore proposed that:

H_{2a}: Service Quality significantly affects Intention to Use social commerce.
H_{2b}: Service Quality significantly affects System Quality.

System Quality (SQ)

System Quality describes the characteristics of the system (DeLone and McLean, 2002). It is the measure of the systems' ease of use, flexibility, reliability and response time (Lwoga and Sife, 2018). Users are more likely to adopt social commerce when they have favorable experiences with the system (Lwoga, 2014). However, whereas Rana and Dwivedi (2015) found significant relationships between System Quality and Intention to Use, findings from Yakubu and Dasuki (2018) and Lwoga and Sife (2018) contradict this claim. Therefore, to confirm this relationship, it is postulated that:

H_3: System Quality significantly affects Intention to Use social commerce.

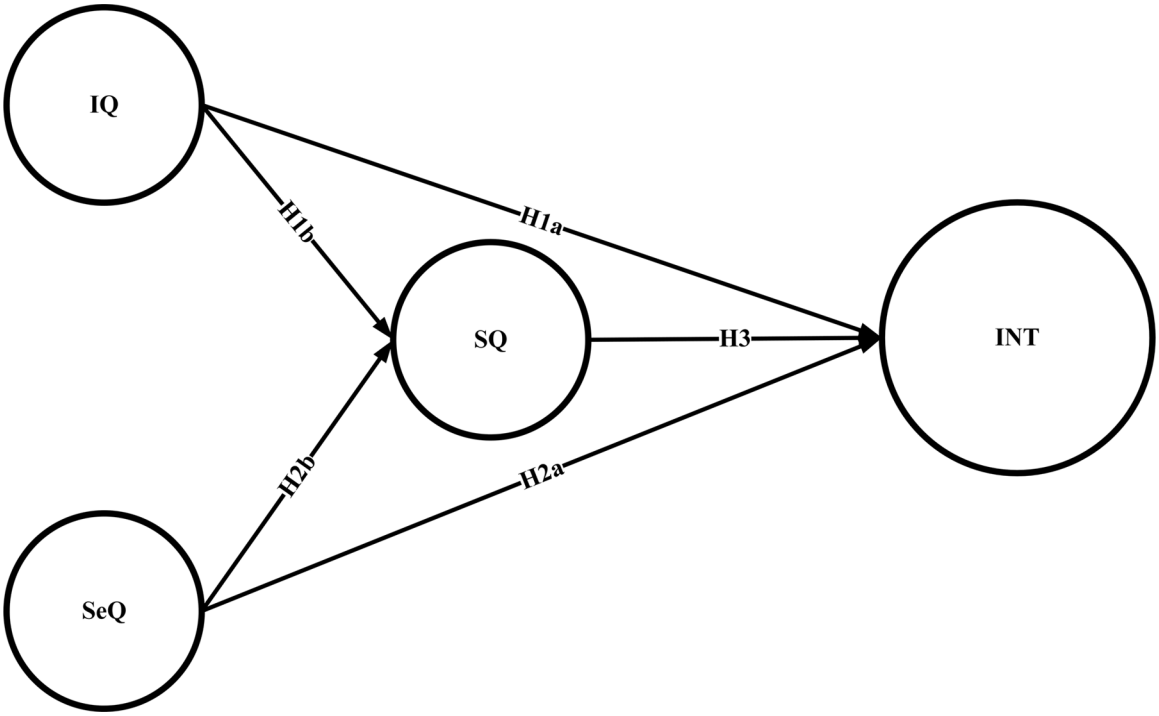
Figure 1. Hypothesized Model



METHODS

An English-based survey questionnaire was developed to empirically test the relationships between the observed variables. The questionnaire solicited respondents' opinions on four constructs; (i) Information Quality, (ii) System Quality (iii) Service Quality and (iv) Intention to Use. Each construct had a minimum of three questions. All questions were adapted from prior studies (see table 1) and adopted a seven-point Likert scale ranging from strongly agree (7) to strongly disagree (1). To ensure anonymity, only relevant demographics were gathered. Links to the questionnaire was posted on social media pages of three (3) universities in Ghana. Participants were also tasked to forward the link via SNS platforms such as Facebook and Twitter. This was to ensure that all participants were familiar with online social networking. Participation was purely voluntary.

Data Collection

After a month of data collection, 614 responses were gathered. All responses were valid because all fields of the questionnaire were compulsory. Out of the total, majority (53%), were male whereas 47% were females. Also, 73% were below 30 years whilst 27% were between 30 and 40 years. Again, majority (90%) of the respondents were undergraduate students and only 10% were postgraduate students.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Respondents' Demographics

Demographics	Value	Frequency	Percentage
Sex			
	Male	325	53%
	Female	289	47%
Age			
	Below 30	451	73%
	30 - 40	163	27%
Highest Education Level			
	Postgraduate	553	90%
	Undergraduate	61	10%

Analysis

The research model was estimated using Partial Least Square Structural Equation Modelling (PLS-SEM) techniques. This is because. PLS-SEM provide potent methods for evaluating the measurement and structural models. Unlike Covariance-based approaches, PLS-SEM is robust to multivariate distribution errors (Gefen, Rigdon, and Straub, 2011). Hence, appropriate for measuring the relationship between latent variables. More importantly, it enables effective mechanisms for predicting the effects of the independent constructs (Hair, Sarstedt, Hopkins, and Kuppelwieser, 2014). SmartPLS 3.0 was therefore used for the analysis.

Measurement Model

In this study, the measurement model assessment emphasized item reliability, internal consistency, convergent validity, discriminant validity and collinearity. All question item loadings were above the required value of 0.7 as recommended by Barclay, Higgins, and Thompson (1995). Internal consistency was measured with the conventional Cronbach's alpha as well as composite reliability. Bagozzi and Yi (1988), recommend that both measures must be above 0.7. This is shown in table 3. With convergent validity, the Average Variance Extracted (AVE) for each construct was juxtaposed with Wixom and Watson (2001) threshold of 0.5. Table 3 indicates that this condition was met.

Table 3. Internal Consistency, Convergent and Discriminant Validity

	Cronbach's Alpha	rho_A	Composite Reliability	Average Variance Extracted (AVE)	INT	IQ	SQ	SeQ
INT	0.732	0.733	0.849	0.653	0.808			
IQ	0.798	0.721	0.818	0.535	0.610	0.731		
SQ	0.787	0.799	0.863	0.613	0.575	0.653	0.783	
SeQ	0.800	0.832	0.869	0.626	0.684	0.616	0.585	0.791

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Furthermore, Fornell and Larcker (1981)'s criteria in addition to Henseler, Ringle, and Sarstedt (2015)'s Heterotrait-Monotrait Ratio (HTMT) were adopted to justify discriminant validity. According to, Fornell and Larcker (1981) the square of AVEs of latent variables should be greater than all other correlations when compared. The highlighted diagonal values in table 3 confirm discriminant validity. Moreover, Clark and Watson (1995) also recommend that the HTMT values require a maximum threshold of 0.85. The values in table 4 show all values were above this threshold. Finally, the possibility of collinearity was examined using Variance Inflation Factor. VIF values lesser than 3 is preferable (Hair, Hult, Ringle, and Sarstedt, 2016). The values in table 5 indicate that collinearity did not affect the results.

Table 4. Heterotrait-Monotrait Ratio (HTMT)

	INT	IQ	SQ
IQ	0.762		
SQ	0.454	0.674	
SeQ	0.472	0.309	0.716

Table 5. Variance Inflation Factor (VIF)

	INT	SQ
INT		
IQ	2.038	1.611
SQ	1.922	
SeQ	1.777	1.611

Structural Model

The structural model was estimated using the bootstrap technique (100 samples). This approach is preferred when the sample size is greater than 100 (Kock, 2010). From the analysis, the research model explained 53.9% of the variance in Intention to Use. Relationship between two constructs was significant when the p-value is less than 0.05. The outcome indicated that all proposed relationships were significant. Thus, Information Quality ($\beta = 0.226$, $p < 0.001$), System Quality ($\beta = 0.166$, $p < 0.005$) and Service Quality ($\beta = 0.447$, $p < 0.001$) had significant influence on Intention to Use social commerce.

Table 6. Significance of Path Coefficients

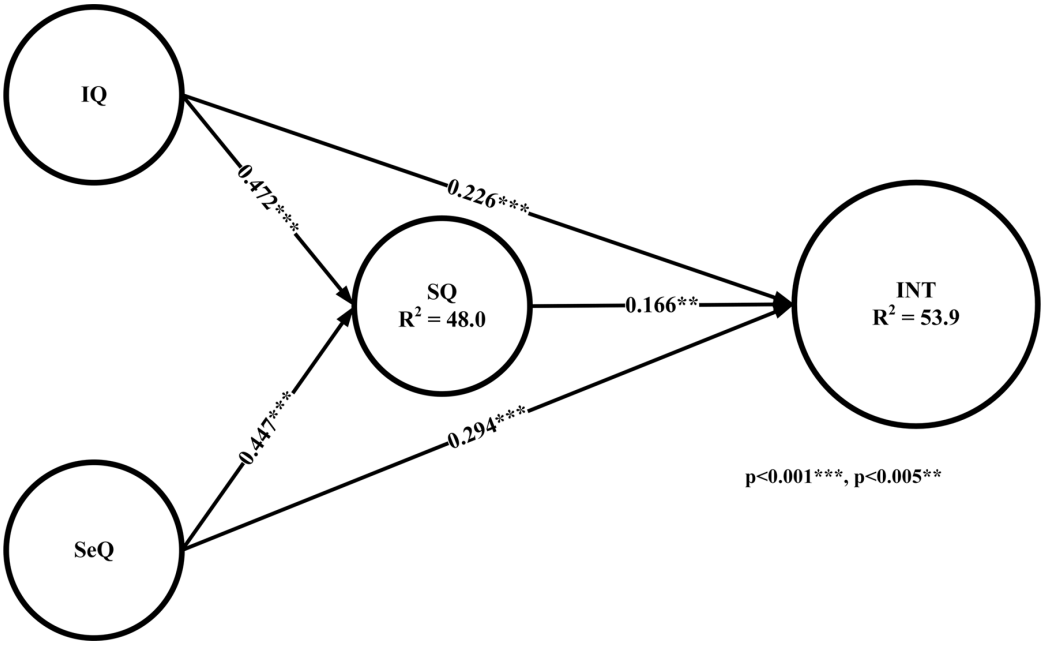
	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	T Statistics (|O/STDEV|)	P Values	Effect Sizes
IQ -> INT	0.226	0.227	0.054	4.213	0.000	0.054
IQ -> SQ	0.472	0.475	0.053	8.864	0.000	0.265
SQ -> INT	0.166	0.164	0.059	2.806	0.003	0.031
SeQ -> INT	0.447	0.449	0.056	8.012	0.000	0.244
SeQ -> SQ	0.294	0.293	0.059	5.023	0.000	0.103

Moreover, Information ($\beta = 0.472$, $p < 0.001$) and Service Quality ($\beta = 0.294$, $p < 0.001$) also predicted System Quality. The effect sizes of constructs were also analyzed. Cohen (1988) asserts that, effect sizes can be irrelevant (i.e. f 2 < 0.02), small (^{3} 0.02), medium (^{3} 0.15) or large (^{3} 0.35). The results show that Service Quality had a medium effect (0.244) on Intention to Use., Also, both Information (0.054) and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

System Quality (0.031) had small effects on intention to Use. Meanwhile, Information Quality (0.265) had a medium effect whereas Service Quality effect on Systems Quality was small (0.103). Figure 2, depicts a pictorial representation of the relationships and table 6 presents a summary of the results.

Figure 2. Structural Model



DISCUSSION

In this chapter, the IS Success model was adopted to investigate the antecedents of users' Intention to Use Social Commerce in developing countries. The research model examined the direct effects of Information Quality, System Quality and Service Quality on Intention to Use Social Commerce. It also evaluated the effects of Information and Service Quality on System Quality.

The findings suggest that the quality antecedents (Information Quality, System Quality and Service Quality) explained 53.9% of the variance in Intention to Use. In addition, all proposed relationships were significant. The results indicate that Information Quality is a key predictor of System Quality and Intention to Use Social Commerce. In other words, users in developing countries are drawn to use social commerce technologies when the information available on these platforms are relevant and reliable. This is consistent with Rana and Dwivedi (2015). As a result, businesses that seek to engage users are advised to satisfy the informational needs of users by generating accurate, relevant and reliable information.

Unlike some prior studies (e.g. Lwoga and Sife, 2018), Service Quality was found to significantly influence both System Quality and Intention to Use Social Commerce. This suggests that when there are readily available and competence support to social commerce users, they are more likely to use the systems. Similarly, when system support staff show concern and empathy, users will appreciate and use the system. In an attempt to encourage usage, it is recommended that timely and relevant support is given

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

to users as they use the system. For instance, an instant chat messenger could be incorporated into social commerce platforms, where support staff could instantly attend to users who need help. Finally, System Quality also had a significant effect on Intention to Use. This confirmed Rana and Dwivedi (2015)'s claims that system response time, flexibility and ease of use are relevant in IS use. However, this finding contradicts Yakubu and Dasuki (2018) findings, though their study was conducted in a developing country. This disparity may be because the stud by Yakubu and Dasuki, (2018) was conducted on an e-learning system which differs from the context of this study. Therefore, businesses that seek to engage users via social commerce must continually maintain the quality of their systems. Perhaps, users could be involved in the design of the systems interface to ensure they are flexible and easy to use.

CONCLUSION

Prior studies that investigated social commerce adoption are predominately reliant on respondents from developed countries. However, the applicability of existing theories is challenged given the factor that technology adoption differs by culture and location. This study adopted the IS Success Model to examine the factors that affect users' intention to use social commerce in developing countries. Using a survey questionnaire, responses from 614 participants were analyzed using rigorous techniques from Partial Least Square Structural Equation Modelling. The findings from this study confirm the applicability of the IS Success Model as a potent framework for examining users' Intention to Use Social Commerce in developing countries context. Moreover, Information Quality, System Quality and Service Quality were found to significantly predict Intention to Use Social Commerce. The study recommends that accurate information and reliable support from staff must be ensured to influence users' usage on social commerce. Meanwhile, the study adopted the convenience sample method. Future studies must, however, explore the model in other developing countries to confirm the applicability of the research model. Moreover, perceived risks, cyber-crime perceptions and trust have been identified to influence Use Behavior in e-commerce and other online technologies. Perhaps, these concepts could be explored within social commerce context. Also, the effectiveness of persuasive features in enhancing the use of social commerce platforms could be studied.

Chapter 67
Exploring Supportive and Deterrent Factors on Online Shopping in a Developing Country

Tolga Pusatli

Cankaya University, Turkey

Ibrahim Akman
Atilim University, Turkey

ABSTRACT

This study explores the influence of the reasons of individuals' supportive and deterrent behaviors against commercial usage of online media in the emerging market of Turkey. The supportive and deterrent factors are grouped in empirical categories as discouragement and encouragement, respectively. The impact of these factors on actual behavior were assessed via intermediary empirical category including the variables inefficiency, efficiency, intention, and subjective norm. A survey was conducted using a sample of 251 observations obtained from the visitors of three large/busy malls using purposive sampling. The multiple least-square regression was utilized to test the nature of the relationships between variables. Results indicated a significant discouraging impact of warranty, finance, habits, security on inefficiency perceptions, an encouraging impact of geography and convenience on efficiency perceptions. Significant behavioral impact of perceptions regarding inefficiency, efficiency, subjective norms, and intention on actual usage of online shopping was also observed.

INTRODUCTION

E-commerce is generally defined as conducting business through the use of the Internet. The rise of gigantic e-commerce sites, such as eBay and Amazon, shows that online shopping proves to be a strong alternative in business-to-consumer and consumer-to-consumer commercial activities, especially in the last decade. The term 'online shopping' is a part of e-commerce and refers to purchasing of products and services using the Internet. Today, companies shifting reluctantly to e-commerce activities and being present in the digital world is recommended not only as an advantage in competition but also as a requirement (Laudon & Laudon, 2016).

As online shopping is becoming more common in society (Criteo, 2015), the reasons and the advantages of using the Internet in commercial activities are highlighted in different studies. Today, the available literature provides studies on conceptual discussions and reviews (Ahmad & Khan, 2015) and (Obadă, 2013); for descriptive surveys (Hassan, Tretiakov, Whiddett, & Adon, 2014) and for modeling of the relationship between individuals' behavioral attributes and the actual usage of online shopping, (Al-Alawi & Al-Ali, 2015) and (Al-Bakri & Katsioloudes, 2015). Most of these studies use a global approach and use a sample of special groups such as industry, academia and professionals. Available literature generally focuses on exploring the factors of actual usage of online commerce in general and does not pay much attention to the distinction for underlying reasons of individuals' supportive and deterrent behaviors against commercial usage of online media. Additionally, the number, nature and relative importance of factors affecting e-commerce adoption may vary depending on business conditions and circumstances in different countries (Al-Bakri & Katsioloudes, 2015). Moreover, the complexity of the area is even amplified with consideration of differences between societies (Çelik, 2011), and the accelerated changes in the technology requires further research in time to see effective internal and external changes in online consumer behaviors for industry, government, consumers and academics (Al-Alawi & Al-Ali, 2015; Obadă, 2013).

For these reasons, this study focuses on citizens' attitudes towards virtual shopping places and aims to research the supportive (positive drivers) and deterrent (negative drivers) factors in selecting online shopping alternative. The adopted research model was developed according to the purpose of this study and based on factors selected from the literature.

Internet purchasing has been developed and better established in countries providing developed infrastructure for commercial activities over the Internet (Jamil & Mat, 2011) and most of the available literature are either from Western or Far Eastern countries. Compared to the Internet potential of developed countries, the growth of the actual number of Internet users and their online purchasing activities is relatively low in developing countries. Consequently, the online commerce literature is immature and there is a clear need for detailed exploration of electronic markets from different perspectives in developing countries (Jamil & Mat, 2011). On the other hand, studies have shown that online shopping behavior may show entirely different patterns for different groups and countries due to the differences in understanding the subject knowledge, technical skills, efficiency of available business models, sufficiency of information sources and available infrastructure (Jin, Drozdenko, & Bassett, 2007). This means opportunities and circumstances to access and use information and communication technologies have an important influence on the use of online purchasing; therefore, findings may show significant differences from one case to another. With this backdrop, the research was based on the data collected in Turkey.

Based on the report by Nielson Group (Akman & Rehan, 2014; Nielsen, 2008) indicated that 'Turkish online shoppers (who represent the economic elite) topped global rankings for credit card usage

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(91%) for online purchases followed by 86% of Irish online shoppers and 84% of Indian and UAE online shoppers'. These figures show that Turkey is a developing country providing a relatively unexplored emerging market having an important potential for online shopping (Hwang, Jung, & Salvendy, 2006).

Recent literature, such as (Başev, 2014; Bulut, 2015; Günüç & Keskin, 2016; Sakarya & Soyer, 2013; Turan, 2012), provides research on online shopping adoption at an individual level. Some of these works use the available structured conceptual models, where the number of factors is limited. For instance, Başev (2014) explores Turkish consumer behavior using a sample of 10 consumers and concludes that their behavior is shaped by lifestyle. The study takes TRA as the research model with the scope of the study being a single online shopping website, namely hepsiburada.com. In another work, Turan (2012) uses TAM and TPB as the research models to explain online shopping behavior based on a sample of Turkish students and academics. In particular, this work investigates the predictive power of TAM and TPB with regard to actual online commercial behavior. On the other hand, Bulut (2015) focuses only on the usage of web sites as online shopping channels. In a more recent work, Günüç and Keskin (2016) used an open ended questionnaire to address the psychological symptoms as the research topic and considered the causes and effects of online shopping addiction. Finally, Sakarya and Soyer (2013) compared the online shopping behavior of two distant cultures, British and Turkish, and explored their respective risks and security. These studies do not provide comprehensive evidence on the impact of important supportive or deterrent factors regarding the online commercial behavior of Turkish citizens and there appears to be a gap in this respect. The current study, therefore, explores the negative and positive factors affecting the adoption of online shopping in Turkey. Rather than using a pre-defined conceptual model with a limited number of factors, we have opted for an original comprehensive model focusing on factors grouped in three empirical categories, namely encouraging, discouraging and behavioral. This approach extends the theoretical insights into the actual use of consumer' online shopping behavior.

HYPOTHESES DEVELOPMENT

The hypotheses of this study address factors influencing citizens' behavior against the dependent variable 'online shopping adoption' (actual behavior) in Turkey. The independent variables were categorized into three empirical factors: (i) discouragement (delivery, service, warranty, finance1, habits and security); (ii) encouragement (finance2, time, geographic and convenience); and (iii) behavioral (inefficiency, efficiency, subjective norm and intention). Figure 1 presents the research model. The nature of experiences related to the deterrent and supportive factors grouped in the first two empirical categories has important role in the enhancement of technical infrastructure and improvement of online commerce adoption in emerging markets like Turkey. Regarding the third empirical category, the factors 'inefficiency' and 'efficiency' appear to be the intermediary variables corresponding to the 'discouragement' and 'encouragement' empirical categories respectively. Subjective norm is a function of an underlying normative belief and it refers to the perceived social pressure and influences of actual behavior (Pudaruth & Busviah, 2018). Most studies report the intermediary role of purchase intentions before performing actual buying (Jamil & Mat, 2011). These have been added as independent outlier factors to our model (Figure 1) and the research model is hypothesized. The variable names are given inside the parentheses in the structure of each hypothesis. As can be seen, this study adopts a new research model rather than using an existing conceptual model since it will hopefully provide different perspectives for the strategists and decision makers in the field of e-commerce.

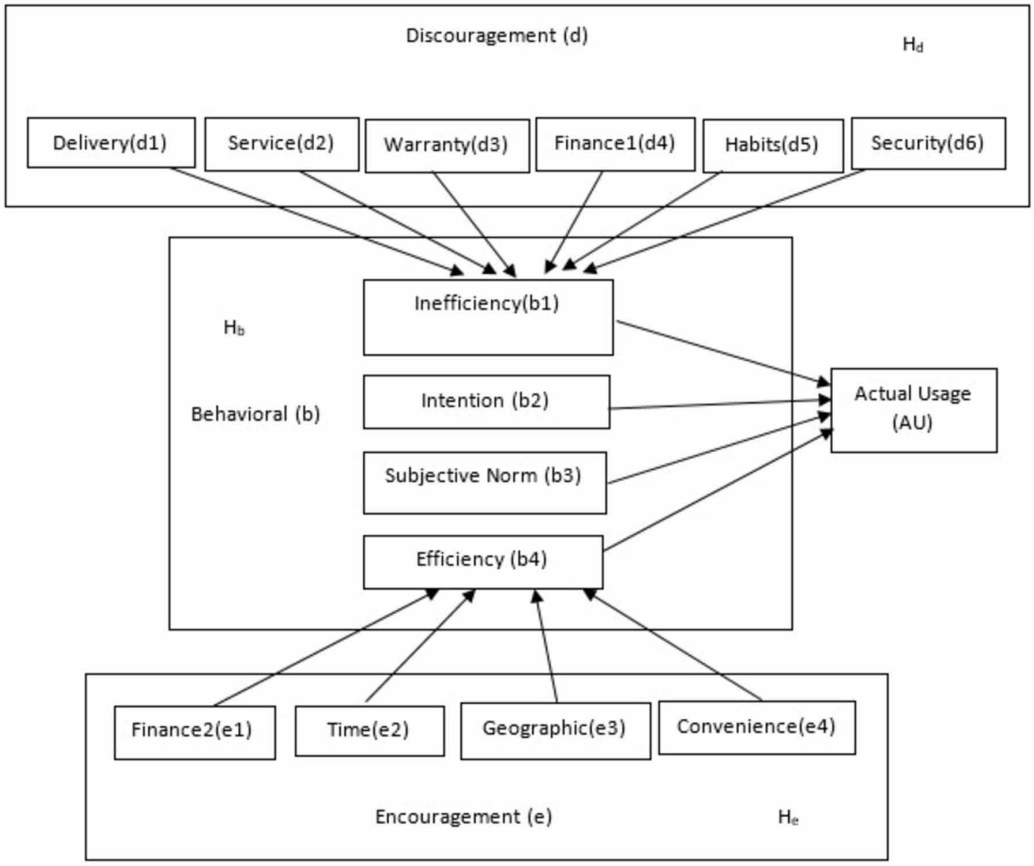
Figure 1. Research model



Discouragement

Some studies have indicated the role of trustworthiness from 'payment' to 'delivery' in electronic commerce. Singh (2013) examined the delivery quality and pointed to its importance for customer satisfaction. (Schlosser, White, & Lloyd, 2006) is another example, which reported that 'delivery problems' have a negative influence on trust and therefore should be considered in electronic commerce studies. Schlosser et al. (2006) also pointed to the importance of developing strategies for building trust, which needs a deeper understanding of any problematic issues in electronic commerce. Aydin and Derer (2015) studied the role of factors in the adoption of electronic commerce using a sample of 1170 students. They identified that 'prejudgments' and 'bad experience' have significant effects on purchase decisions. All these factors may be used as the reasons for developing the following hypothesis regarding 'delivery' problems.

H_{d1}: Delivery problems (delivery) have no discouraging influence on inefficiency (inefficiency) towards online shopping adoption.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The ease of use of a site also plays a considerable role as user friendly online sites show more retention of customers (Etemad-Sajadi, 2016). Another point with the service is providing facilities and points of interest in the vicinity. In (Eklund & Pessi, 2001), it is reported that potential customers would like to find what they are seeking with advices. The work found the support of expert recommendations on products improves online shopping. In another work, Guo, Wang, and Leskovec (2011) analyzed a large e-commerce website which provided an instant messaging tool to connect the potential customer with the vendor. This utility was found to make the site more desirable. Furthermore, Singh (2013) pointed out service quality to be pertinent to the customers' selection process, and therefore, a major challenge to e-commerce retailers. These works take quality of online services being an effective part in online shopping. With this backdrop following hypothesis is proposed.

H_{d2}: Poor service quality (service) has no discouraging influence on inefficiency (inefficiency) towards online shopping adoption.

We take the warranty covering both wrong/faulty products and return in this work. A high rate of product returns has been reported as consumers do not always have clarity when buying (Susanna Kim, 2013). Receiving an unexpected product is not always due to a confusion in transactions; it is due to asymmetric information between the seller and the buyer (Fidan & Albeni, 2014). Basically, the customer can receive a low quality or wrong product. This is less likely to occur in traditional shopping as the customer has the opportunity to examine the product at the point of purchase. Additionally, there may be a number of problems while returning the product. The literature is criticized such as by (Fu et al., 2016) that not many systematic works are reported on explaining reasons driving return requests and propensity despite the fact that there is a considerable portion of return in online shopping. According to the results of (Berthiaume, 2015), a large majority of customers wanted free return shipping offered at the time of purchase and little or no restocking fees for online returns. Therefore, following hypothesis is postulated.

H_{d3}: Warranty problems (warranty) have no discouraging influence on inefficiency (inefficiency) towards online shopping adoption.

The delivery fee in online shopping becomes an issue because, customer does not choose the delivery method; hence delivery cost does not depend on the buyer in such purchases. In (Miyatake, Nemoto, Nakaharai, & Hayashi, 2016), the authors highlight delivery fee as a hidden cost; e.g., when purchasing more than one item from the same place, there are cases where the delivery cost may increase without any reasonable cause. The transaction cost as a separate, additional cost has been in discussion since the early years of Internet shopping; e.g. Akturk, Ketzenberg, and Heim (2018) report that customers are concerned with this fee as uncertainty. Similarly, in (T. S. H. Teo & Yu, 2005), customer perceived transaction cost is found to be associated with uncertainty and it negatively effects willingness to do online shopping. These extra costs can be visible or invisible, surprising the buyer at time of payment and need to be explored (Wu, Chen, Chen, & Cheng, 2014). We address shipping costs and any other extra costs under the finance1 factor and propose following hypothesis.

H_{d4}: Financial costs (finance1) have no discouraging influence on inefficiency (inefficiency) towards online shopping adoption.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

When customers go shopping, they usually prefer to have their hands touching a product. Negotiating on price and service is another dimension in traditional shopping. However, this does not occur in e-commerce. Activities such as negotiating on price and assessing a product in advance are basically competencies we have in traditional shopping. Additionally, looking at stores and searching for the products we want and comparing them in detail by traditional means is also our habit. Considering these points, habits basically play a considerable role in opting for or rejecting online shopping. Therefore, we propose following hypothesis.

H_{d5}: Habits (habit) have no discouraging influence on inefficiency (inefficiency) towards the actual use of online shopping.

As customers shop online, their private information such as home/work addresses and demographic information can be collected for niche marketing purposes. The aim of the website may not be to make such information public; however, customers may feel uncomfortable knowing that such information is collected and can be shared easily. A work published in 2011, (X. Wang, 2011), delves into the details of this issue in the supply chain. Basically, when the customer provides such information, this can be shared among the entities in the supply chain. For this reason, having to provide such information, especially credit card details, can increase reluctance toward online shopping. As mentioned, what the customer provides to the website may not remain only on that website not only intentionally but also due to unsafe network transactions (Sun & Wang, 2010). Regarding these works, following is used to test user behaviors in security related risks on providing both private information and credit card details.

H_{d6}: Security concerns (security) have no discouraging influence on inefficiency (inefficiency) towards actual use of online shopping.

Encouragement

Works such as (Nethra & Dhanaraj, 2016) further investigate lower prices not only on product labels but also saving money by not leaving home. For instance, Amazon's ebook reader, the Kindle, can be purchased only online because the company's business model basically disintermediates entities, such as retail shops between the company and the customer. In this manner, products can be offered at lower prices leading to customers being able to save money. However, this business strategy compels the customer to shop online. In addition to savings, large online market sites such as n11.com offer coupons, promotions and flexibility in payments regardless of the seller. Prior literature has not explored the financial advantages of online shopping significantly in our context and therefore following is proposed.

H_{e1}: Financial advantages (finance2) have no encouraging influence on efficiency (efficiency) towards actual use of online shopping.

Generally limited places can be visited in traditional shopping and the customer is restricted to the physical shops in the his/her vicinity. In market spaces in the Web, customers can investigate more alternatives in a shorter time. Additionally, access time flexibility, such as being available online while shops are closed in the off-hours, is another advantage. In (Miyatake et al., 2016), the researchers take saving

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

time as not only about reducing time to shop but also as being able to order a product outside business hours. Hypothesis He2 tests the saving time influence on behavior to do online shopping.

H_{e2}: Time saving (time) advantages have no encouraging influence on efficiency (efficiency) towards actual use of online shopping.

We have taken the geography factor to refer to the location of the customer and his being able to access online stores regardless of the physical or cyberspace location. Firstly, it is worth stating that potential customers are happy to know where to find the product they are seeking. For instance, in (Eklund & Pessi, 2001), about two decades ago, the researchers found that mobile phone applications showing information about a product customers are seeking were found to be useful. In the study, e-commerce with a mobile phone was investigated and the researchers concluded that the places where the product and its shipping information are available were found to encourage online shopping. As for the effects of living in a remote or urbanized area on online shopping, (Nethra & Dhanaraj, 2016) can be given as a good matching example reporting a case study in India. The research found that although consumers were living in a city where brick and mortar shops were available, they still may prefer online shopping. Moreover, accessing from anywhere, was taken as one of the customer retention tactics; for instance, Lazazzera (2014) recommends sellers not only be available online but also connect to their customers via social networks, hence informing them the e-shop is always open and accessible. The work reports such activities could have customers shop from the same place again. Based on this discussion the advantage of geographical independence has been hypothesized as follows.

H_{e3}: Geographical independence (geography) has no encouraging influence on efficiency (efficiency) towards the actual use of online shopping.

One of the advantages of the market space against the market place is that customers can see numerous sellers of the same or alternative products on the Web. When making comparisons in the price of a product, for instance, user-agents can scan websites selling a product the customer is seeking and list them in the desired order. Convenience, in this scope, covers easily comparing alternative products/vendors and making quick and correct decisions. The concept of convenience is studied in the literature with different definitions. For example, in (Tontini, 2016), usability and information were taken as a dimensions of convenience. This dimension also includes a comparison of prices as well as information on products sold. Khanh and Gim (2014) and Sen (2014) used convenience in terms of time saving only. Our perspective differs from these studies. Therefore, following is postulated.

H_{e4}: Convenience (convenience) has no encouraging influence on efficiency (efficiency) towards actual use of online shopping.

Behavioral

It is natural that customers tend also to find the comfort of traditional shopping in online shopping. Hence, inefficiencies (H_{b1}), such as receiving lower quality product or delays in the delivery, are open to discussion. While shopping face-to-face, we see the product and we can judge its status and quality on the spot and we can take the product at the moment we decide to buy it. However, the purchaser is more

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

likely to experience problems, including disappointment in the quality or sometimes receiving damaged products in online shopping. In (Susanna Kim, 2013), high rates of returns due to such problems have been reported.

The problems are not only limited to such issues; they also include problems in delivery time and place as reported in (Inside Retail, 2016), where the authors underline delivery problems to be among the main frustrations of online shoppers. We gather the problems of receiving unexpected low quality, damaged products and not receiving the product on time/place under 'inefficiency' in the following hypothesis.

H_{b1}: Inefficiency (inefficiency) has no any influence on actual use (actual usage-AU) of online shopping.

Efficiency, as in correctness and speed in online shopping, is also a factor we consider with behavior. In this scope, we name 'efficiency' as making a correct decision in a shorter time while shopping online. In support of this, Nethra and Dhanaraj (2016) underline the speed of the purchase decision in online versus traditional shopping. Their statistical analysis method differed from ours; however, they found that online shoppers tended to spend less time and effort on completing their purchases. Related to making correct decisions in less time, in (Tontini, 2016), it was found that speed and accuracy of responses as 'responsiveness of the site' should be considered as a quality dimension. This factor is one of the reasons individuals prefer online sites instead of brick and mortar shops. Therefore, following hypothesis is worth to propose.

H_{b2}: Efficiency (efficiency) has no influence on actual use (actual usage-AU) of online shopping.

The subjective norm is simply defined as the social pressure. In (Moshrefjavadi, Dolatabadi, Nourbakhsh, Poursaeedi, & Asadollahi, 2012), the researchers investigated the role of subjective norms in online shopping and found that people care about what others are thinking. In another work, Akman and Mishra (2017) argue that interviewees consider what others think and do in online shopping. Hence, we have decided to survey the influencing role of subjective norms on the actual use of online shopping.

H_{b3}: Subjective norm (subjective norm) has no any influence on actual use (actual usage-AU) of online shopping.

Identifying typical online shoppers is a common goal in many shopping sites. For this reason, the literature contains a considerable number of works on the intention of shoppers. Works such as (Järveläinen, 2007; Jusoh & Ling, 2012) attempt to find indicators in this subject, including socio-demography, patterns of online buying and purchase perception to model and predict what customers will do subsequently. In most of the models presented in the literature, 'intention' has been investigated as a separate item. Another example can be given in (Ramayah & Ignatius, 2005), where the authors investigate perceived usefulness, perceived ease of use and perceived enjoyment to predict intention of shopping online.

Hence, we have decided to investigate the role of intentions adopt online shopping.

H_{b4}: Intention (intention) has no influence on actual use (actual usage) of online shopping.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

RESEARCH METHOD

The survey instrument was prepared to contain 35 questions (Table 1). The first six questions in the personal category are related to socio-demographic characteristics and were used for descriptive purposes. The remaining questions were grouped under 14 constructs focusing on testing the hypotheses. The research sample contained 251 observations obtained from visitors (potential customers) of three of the largest/busiest shopping malls in the city. Voluntary face-to-face participation was utilized in this study and the data were collected at weekends. Of the respondents, only the users of online shopping were included in the analyses.

A pilot survey was used with experienced professionals and then finalized according to their suggestions. A five-point Likert Scale (5 = strongly agree, 4 = agree, 3 = neutral, 2 = disagree, 1 = strongly disagree) was used for non-descriptive items. 'Actual usage' is the dependent variable; 'inefficiency', 'efficiency', 'subjective norm' and 'intention' are the mediating variables, whereas other non-descriptive variables serve as the independent variables (Table 1). In this study, the multiple least-square regression method was utilized to test the nature of the relationships between the variables, as follows:

$Y_i = a_0 + a_{i1} x_{i1} + a_{i2} x_{i2} + \ldots + a_{in} x_{in}$ i= discouragement, encouragement, behavioral; n=6,4,4,

The chi square test method was also used whenever needed.

The scale reliability measure for the whole instrument, Cronbach's alpha, was found to be 0.798, which shows sufficient internal consistency since 0.7 and above is usually the acceptable threshold (Matsunaga, 2010). The reliabilities of multi-item constructs are summarized in the last column of Table 1 and are ranging from 0.551 to 0.837, which means that the constructs are reliable. In order to ensure content validity, the items were taken from the available literature and modified according to the purpose of this study.

Table 1. List of variables and constructs

Construct/Variable name	Item	Cronbach's alpha
PART 1: Personal		
gender	Male/Female	-
age	<20, 21-30, 31-40, 41-50, >50	-
sector of work place	Public, Private, University, Student, Housewife, I do not work	-
level of education	primary/secondary, High School, University/Vocational, Master, Ph.D.	-
IT Experience	I am professional, I am confident, I am not very confident (reasonable)	-
online shopping awareness	very less, less, Moderate, Much, Very much	-
PART 2: Discouragement		
delivery	I think problems for the delivery of purchased products is discouraging towards online shopping.	0.820
	I think fear of non-delivery of order is discouraging towards online shopping.	
service	I think company's poor quality in online services is discouraging towards online shopping.	0.798
	I think having difficulties in communication with company is discouraging towards online shopping.

Table 1. Continued

Construct/Variable name	Item	Cronbach's alpha
warranty	I think details/problems in product warranty covering such as wrong or faulty products is discouraging towards online shopping.	0.777
	I you think details/problems in return issues is discouraging towards online shopping.	
$finance_1$	I think the risk of losing money is discouraging towards online shopping.	0.593
	I think shipping charge is discouraging towards online shopping.	
habits	I think traditional shopping habits negatively is discouraging towards online shopping.	0.765
	I think lack of competence is encouraging towards online shopping.	
security	I think the risk of unauthorized use of your private information is encouraging towards online shopping.	0.722
	I think risk of unauthorized use of your credit card is encouraging towards online shopping.	
PART 3: Encouragement		
$finance_2$	I think saving money is encouraging towards online shopping.	0.861
	I think payment benefits such as coupons promotions and elasticities in payments is encouraging towards online shopping.	
time	I think saving time is encouraging towards online shopping.	0.874
	I think access time elasticity i.e. 24/7 accessibility is encouraging towards online shopping.	
geography	I think the advantage of being independent of residential area is encouraging towards online shopping e.g. some items may not be available in rural areas.	0.755
	I think advantage of accessing from anywhere is encouraging towards online shopping.	
convenience	I think easiness in making comparison with alternative products/vendors is encouraging towards online shopping.	0.562
	I think making quick and right is encouraging towards online shopping.	
PART 4: Behavioral		
inefficiency	Compared to traditional shopping I encounter various problems in your online shopping such as expected quality and damage in delivered product.	0.831
	Compared to traditional shopping I encounter various problems in delivery time of the product in your online shopping.	
efficiency	When I do online shopping it does not take much time to reach correct purchase decisions as compared to traditional shopping.	0.656
	When I do online shopping I come up with more correct purchase decisions in a shorter period of time as compared to traditional shopping.	
subjective norm	I think most people who are important to me think that I do online shopping.	0.551
	I think that most people who are important to me do online shopping.	
intention	In general, I intend to do online shopping.	0.837
	I plan to do online shopping in the future.	
actual usage	I frequently use online shopping?	-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

RESULTS

Descriptive Results

According to the descriptive results (Table 2), most of the respondents were female (70.5%), younger than 31 years (67.7%) and working (61.8%). Of the females 68.74% reported that they use Internet for online shopping. Interestingly, this percentage is slightly less for males (63.39%). More than 30% reported lack of Internet access for both genders, which can be an indication of existence of lack of access to Internet in Turkey. Age appears to be significant in terms of the adoption of online shopping (chi square = 29.872; df = 16; p value = 0.019). Additionally, of the females who indicated their age to be less than 31, 56.6% declared usage of the Internet for commercial purposes to be 'average' or 'more'. This percentage for male respondents is higher (65.4%), meaning that younger males intend to perform online commerce more than their female counterparts. However, this difference is not significant (chi square = 2.128; df = 4; p value = 0.712). It has also been observed that only 5% of the respondents over 40 years of age declared their use of online shopping. This may be an indication of unfamiliarity of older people with online shopping and their preference for conventional shopping.

Graduates of vocational school, university or higher constitute the largest group (57.8%) in terms of education level in the sample. The chi square test does not show any difference between educational levels in terms of online shopping awareness (chi square = 13.460; df = 12; p value = 0.337). It is observed that higher educated respondents use the Internet for other (non-commercial and non-entertainment) purposes more than lower educated ones. However, the level of awareness shows differences depending on the IT experience level of the respondents (chi square = 43.241; df = 9; p value = 0.000) and higher experienced people seem to do Internet shopping significantly more than lower educated people (chi square = 24.806; df = 8; p value = 0.002). This is probably because higher IT experienced individuals more often have computers, Internet address, or e-mail at home and/or office, which may result in their disproportional Internet usage for commercial purposes in the country. This may also be the reason of the fact that existing online shopping alternatives in Turkey require increasing level of IT experience.

Test Results

Table 3 presents the results.

Discouragement

Inspection of the test results in the last column of Table 3 indicates the variables 'delivery' (coeff.= 0.046, p value = 0.353) and 'service' (coeff.= –0.018, p value = 0.755) are not supported by the test results. This means that the evidence is not sufficient to decide that delivery problems and service quality affect users' inefficiency perceptions towards the adoption of online shopping; therefore, H_{d1} and H_{d2} both failed to be rejected. The remaining factors of 'warranty' (coeff.= 0.157, p value = 0.017), 'financial' (coeff.= 0.227, p value = 0.000), 'habits' (coeff.= 0.144, p value = 0.001) and 'security' (coeff.= 0.404, p value = 0.000) show significance regarding their discouraging effects. Therefore, H_{d3}-H_{d6} are all rejected. This means that problems regarding warranty/return issues, the risks of losing money during online shopping and due to shipment charges, conventional shopping habits and lack of competence, as well as the risks

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of unauthorized use of personal information/credit card were perceived by the respondents as important drawbacks of online shopping activities.

Table 2. Descriptive results

Agree	79	31.4
Strongly agree	61	24.5

Encouragement

Based on p values in the last column of Table 3, two out of the four hypotheses were supported by survey data at either 0.10, 0.01 or 0.001 significance levels. Surprisingly, the perceptions for the possibility of

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

financial (coeff.= –0.0176, p value = 0.790) saving do not have encouraging influence towards individuals' adoption of online shopping. This means that there is no sufficient evidence to reject H_{e1}. However, although not very strong, the test results supports the encouraging effect of time saving (coeff.= 0.135, p value = 0.094) on online shopping usage of individuals. This leads to rejection of H_{e2}. Interestingly, based on the corresponding p value, the evidence is sufficient such that the advantage of being independent of individuals' residential geographic position (coeff.= 0.215, p value = 0.005) appears to be one of the encouraging factors for efficiency perception regarding online shopping. Similarly, the ease of making comparisons and the possibility of quick/right decisions with online shopping (coeff.= 0.349, p value = 0.000) also show significant influence on efficiency perception towards online shopping adoption. In other words, H_{e3} and H_{e4} are both rejected.

Behavioral

Interestingly, all the mediating factors hypothesized to test the effects on online shopping adoption, such as inefficiency (coeff.= –0.064, p value = 0.014), efficiency (coeff.= 0.096, p value = 0.002), subjective norm (coeff.= 0.210, p value = 0.000) and intention (coeff.= 0.272, p value = 0.000) are supported by the survey results and therefore we reject H_{b1}, H_{b2}, H_{b3} and H_{b4} completely. Naturally, the coefficient of inefficiency was found to be negative, meaning that individuals consider disadvantages (discouraging effects) of online shopping and abstain its adoption. Moreover, its positive coefficient (coeff.= 0.096) efficiency shows a supporting, i.e., encouraging, effect on online shopping adoption. As expected, social pressure is an important factor in online shopping adoption and it has the second highest effect (coeff.= 0.210) in this respect. Intention has the highest influence on actual behavior since its coefficient (coeff.= 0.272) is the largest among the others in this category.

Table 3. Test results

Empirical category	Predictor	Dependent variable	Hyp.	Predictor var.	
				Coeff.	p-val.
Discouragement	Delivery	Inefficiency	H_{d1}	0.046	0.353

DISCUSSIONS

Discouragement

Our results indicate that individuals perceive 'warranty' and 'finance1' to be significant discouraging factors for the adoption of online shopping. This may be taken as an indication of immatureness of digital market in Turkey, hence insignificant infrastructure, design and information content of national e-commerce web sites. Consequently, potential online shoppers are puzzled and, most of the time, their requests for revisions are not taken into account by the national enterprises owning these sites. Our finding is supported by Moshrefjavadi et al. (2012), who reported that consumers take into account all the risks related to an item that they wish to purchase online. They concluded that perceived risks regarding infrastructure, return policies and financial losses, shipment charges and the possibility of non-delivery have a negative effect on human behavior. As noted by Bulut (2015), the most frequently cited risks in online commerce include product quality risks, risks in ordering and returning a product, and the risk of non-delivery. In other words, reservations regarding delivery and quality of an order have a negative impact on virtual media shopping attitudes (Moshrefjavadi et al., 2012). Moreover, fear related to financial issues has a significant negative effect on attitude (Moshrefjavadi et al., 2012). These may be explained by the findings of Bulut (2015), who noted that inherent ambiguity and risks in the online shopping process have an effect on actual behavior through perceptions. This can also be generalized by the study of Biswas and Biswas (2004) stating that people adopt negative attitudes towards online shopping when they observe problems in a retailer's trustworthiness and seriousness.

The existence of the influence of 'habits' was amongst our findings. This is compatible with Ramayah and Ignatius (2005), who stated that 'in spite of putting considerable effort to prosper online commerce by public and private sectors, traditional shopping is still an instinctive choice for most of customers'. In a report (Heffron, 2011), it was observed that more than half of the respondents preferred not to change their attitude to shopping from physical stores. This unwillingness to change behavior may be an indication of the effect of normative and collectivist culture in Turkey. This research concludes that security is also related to inefficiency perceptions which may be based on (Akman, Yazici, Mishra, & Arifoglu, 2005) pointed existence of number of legal issues including security, protection of individual rights remaining to be solved as key barriers in Turkey. Ramayah and Ignatius (2005) also supported our findings that security risks in online shopping develop cynicism in Malaysia and more than one-third of individuals are more comfortable with shopping from physical stores because they worry about personal credit card detail disclosure. As a result, with a reference to (Heffron, 2011; Y. J. Lim, Osman, Salahuddin, Romle, & Abdullah, 2016) stated that 63% of the consumers would make a survey on the Internet before they proceed to purchase traditional consumer electronics online; however, only half of the consumers will purchase online.

Encouragement

Despite existing risks and uncertainties in the online media, there are also important advantages and benefits especially in online shopping transactions. Online media are completely different from those of traditional businesses and they represent a new environment for commercial behavior encouraging individuals for its adoption (Akman & Mishra, 2017). Generally, the success in online shopping highly depends on a comprehensive understanding of the nature and extent of consumers' online information

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

access and shopping attitudes, especially in online commerce website design (Moshrefjavadi et al., 2012). As stated by Moshrefjavadi et al. (2012), innovativeness positively influences online shopping behavior positively. Visual incentives, text communication and sound effects can play significant role in consumers' perceptions, demand and activities (Vijayasarathy & Jones, 2000). The current trend forces corporations and individuals to use virtual media for their online shopping activities as they exhibit money and time advantages (Z. Y. Lim, 2015). The literature also reports other tangible advantages of online shopping encouraging consumers towards its adoption. For example, according to Jusoh and Ling (2012), reductions in a buyer's working out time, better purchase judgements and more opportunities to compare alternative products can be counted as driver advantages. Additionally, they also pointed out the advantage of having geographical and time friendly characteristics (Jusoh & Ling, 2012). Moshrefjavadi et al. (2012) supported all these views by stating that 'online stores have many advantages as they are convenient and time saving, no traveling and waiting in lines is needed, and they are open in all time and they are accessible anytime and anywhere'. They also mentioned that users of online shops can benefit from extensive information pertaining to goods and services regarding delivery, payment, warranty, etc. free of charge. In other words, the interactivity is a distinguishing feature helping customers to shop effectively in terms of product or service comparisons and decision making without encountering any salesman's pressure (Moshrefjavadi et al., 2012). Our findings are in line with these studies such that 'geographic' (coeff.= 0.215; p value = 0.005) and 'convenience' (coeff.= 0.349; p value = 0.000) are significantly positively related to efficiency perception towards adoption. In other words, the efficiency advantage in comparing, evaluating and buying, and of having geographical independence have significant predictive power towards actual behavior. These finding may be partly explained by the fact that there are significant differences in shopping opportunities between metropolitan and rural areas in Turkey. On the other hand, the time saving advantage of this technology is also found significant. All these may be used as an indication of the fact that consumers are especially concerned with their tangible advantages from new commercial technologies in Turkey. Therefore, entrepreneurs, who have decided to incorporate the Internet into their marketing strategies should choose an easy-to-use platform that appeals to consumers in order to promote the advantages of online commerce adoption. Interestingly, our findings are not in favor of the variable 'finance2', which concludes that the advantages related to promotions, such as coupons, credits and discounts, do not appear to be the main concern from the consumer's point of view. This is probably due to promotions being the tools used on all marketing platforms, and hence in conventional marketing.

Behavioral

The results provide strong indications of the influence of behavioral factors on actual online shopping behavior since all the p values in Table 3 indicate significance in this category. Naturally, inefficiency has a negative coefficient (coeff.= –0.064), indicating that it has meaningful unfavorable pressure on motivation for online shopping adoption. The remaining factors, such as efficiency, intention and subjective norm, leverage the use of online shopping.

Our findings coincide with some of the available studies. Regarding inefficiency, the consumers are not happy with online commerce when they encounter problems and difficulties in its utilization, which also addresses the quality and period of delivery (Oracle, 2011). According to Punj (2012), losing time and money are two strong negative predictors of online commerce intentions, which may also arise from delivery and quality problems; also in (Punj, 2012), it is indicated that consumers from higher income

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

level groups are concerned about the time-saving advantages of online shopping more so than the money-saving feature. According to his study, saving money is mainly the concern of low-income customers. These findings suggest that the main challenge for retailers is to develop online strategies and tools to avoid perceptions regarding time and money saving risks arising from inefficiency of systems. Additionally, vendors should consider the gap between different economic classes of the society in developing strategies so that users may individually and equally benefit from these technologies (Punj, 2012).

Efficiency has been reported by various researchers to affect online shopping. Firms can achieve tangible improvements with operational efficiency (Hong & Zhu, 2006). At the early years of online shopping, Hoffman, Novak, and Peralta (1999) indicated that efficiency is a critical characteristic of online commerce platforms compared to traditional physical commerce. As they noted with the advantage of interactivity, more control is provided with online media than physical stores. Better opportunity in accessing and retrieving information on products and services to be purchased is also a key feature in achieving efficiency (Hoffman et al., 1999). Online stores reduce transaction costs and provide advantages to both consumers and vendors (Laudon & Laudon, 2016). For this reason, researchers and vendors struggle to identify the appropriate conditions and factors for the promotion of online shopping (H. H. Teo, Wei, & Benbasat, 2003). Additionally, vendors of online shopping expend effort to satisfy their customers with regard to their efficient service of delivery (Ganapathi, 2015). However, perceptions regarding technical efficiencies reveal discrepancies depending on the region or country. For example, citizens average perception of technical efficiencies differ between American, European and Asian regions (Y. H. Lin & Hong, 2010), in which case the first has the highest and the last the lowest expectations. Since we found efficiency (coeff.= 0.096, p value < 0.002) to be a significant positive predictor for actual behavior, our finding is in line with these studies. However, the literature is not conclusive regarding the role of efficiency. For example, Aurifeille and Quester (2000) stated that the efficiency in online platform logistics is not perceived by consumers. In (Aghdaie, Piraman, & Fathi, 2011; Hu et al., 2009) it is reported that efficiency is not related to actual behavior. The inconsistencies between the results may be due to the different standpoints of respondents depending on socio-demographic factors. Decisions regarding the adoption of online shopping may also vary depending on the level of development of consumers' mother countries (El-Khatib, 2011).

In this study, the subjective norm is defined as perceived social pressure in individuals' online shopping adoption. Our findings provide strong indications for the significant existence of its influence on actual behavior. This means social pressure is proportional to the adoption of online shopping since its coefficient was found to be significantly positive (coeff = 0.210, p value < 0.001). Our finding may be partly explained by the fact that the role models in societies have an important impact on purchase decisions for electronic shopping (Venkatesh & Brown, 2001). Another explanation may be based on the normative and collectivist culture of citizens in the country as noted before. On the other hand, perceived risks and trust are highly important and also significantly related to collectivist behavior of consumers in online shopping, in which case people give high priority to group interests and norms (Cheung & Chang, 2009). Furthermore, online shopping is still in its infancy in Turkey and new for some groups in the society, and the role of social pressure is likely to be more critical during the early stages of the implementation of this new technology since experience is limited for developing a behavior (Moshrefjavadi et al., 2012). In (Moshrefjavadi et al., 2012) factors having an impact on the adoption of electronic shopping using a sample of 120 customers are examined. Their results are in line with our view that social pressure, has a positive influence on the adoption of online shopping. (Järveläinen, 2007; Khalifa & Limayem, 2003) are two other supporting examples from the literature. According to them,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the opinions of friends, relatives and peers are important in developing online shopping behavior and therefore likely influence consumers' online shopping adoption. The existence of the positive effect of social pressure can increase positive perceptions towards the adoption of online shopping. There exist studies reporting conflicting findings in the literature. In (Cheung & Chang, 2009), it is reported that social exchange does not have a significant effect on online vendors and customers do not take social exchange into consideration in developing actual behavior. H.-F. Lin (2007) reported insignificance of subjective norms in online textbook purchase intention of undergraduate students. Similarly, according to M.-S. Wang, Chen, Chang, and Yang (2007), attitudes toward Internet purchasing were not affected by subjective norms. Finally, findings in (Jamil & Mat, 2011; Y. J. Lim et al., 2016) proposed that subjective norms have a marginal insignificant influence on actual online shopping behavior. The conflicting results may be explained by Cheung and Chang (2009) and Bulut (2015). It is reported in these studies that the differences between the nature of the samples, the differences in social group memberships and factors are subjected to differences in social pressure. Additionally, the concerns of customers from different cultural origins may also differ (Cheung & Chang, 2009). They may prefer to visit a market place and show unwillingness towards an online medium because of the social element of conventional shopping (Moshrefjavadi et al., 2012).

Intention has been one of the major areas studied in management information systems and marketing science (Hongyao, 2013). In his original article, Ajzen (1991) suggested intention to be a predictor of an indicator of online shopping adoption and lack of consumers' intention was reported to be a handicap in developing online shopping (Y. J. Lim et al., 2016). Our test results indicate that intention is a strong predictor (coeff.= 0.272, $p < 0.001$) of online shopping adoption. There exist parallel research findings in online commerce literature. (Chen, Shen, & Chen, 2014; Khan & Sadiq, 2015; Mulero & Adeyeye, 2013) are only three examples from recent studies. Khan and Sadiq (2015) reported that the relationship between consumer intention and usage of social commerce exists. Mulero and Adeyeye (2013) indicated a strong positive correlation between user intention and social network marketing usage. Chen et al. (2014) used the concepts of social sharing and social shopping to investigate individuals' intentions. They reported significance of intention in social shopping. The findings from these examples do not fit with some others in the literature. For example, it is an observation of Ajzen, Brown, and Carvajal (2004) that people may fail to act in accordance with their stated intentions. Soyoung Kim and Jones (2009) also supports this view by pointing out that online shopping intention does not always lead to actual adoption behavior. A possible reason for conflicting results may be factors correlated to online shopping but not included in the analyses.

CONCLUSION

From the discouragement standpoint, the findings show a significant impact of Warranty, Finance1, Habits and Security factors on inefficiency perception regarding online shopping. In other words, respondents perceive online shopping to be inefficient due to:

- problems in warranty for faulty product and return of unwanted purchase;
- risk of losing money and extra payment of shipping charges;
- traditional shopping habits and lack of competence; and
- the risk of unauthorized use of personal information and unauthorized use of credit cards.

It is obvious that retailers should focus on avoiding discouraging factors in developing their online commerce business. The encouragement factors, Geographic and Convenience, have been found to influence efficiency perceptions for online shopping adoption. In other words, problems of residential areas in accessing market places and the advantage of having geographic independence of electronic commerce affect perception for online shopping efficiency positively. Electronic commerce entrepreneurs may use these findings to promote their online shopping businesses. Furthermore, all the intermediate factors, inefficiency, efficiency, subjective norm and intention, have been found to emerge in actual online shopping behavior. More clearly, the possibility of experiencing problems regarding quality and delivery of the product, the advantages of effective purchase decisions, social pressure and intentions for now and the future all affect online shopping adoption.

The primary limitation is that online shopping is taken as the scope of this research. An inspection can be suggested as to the effect of using social media for commercial purposes for different demographic characteristics in societies. Furthermore, online shopping can also be studied and we can compare cultural and social perspectives so that the underlying reasons in behaviors may be better investigated. As a follow-up work, enforcement can be investigated as to whether it has a considerable effect on actual behavior. However, factors to nominate enforcement should be found and surveyed separately. Thus, a new research avenue can be created that answers questions such as 'are customers pushed to purchase online?' Finally, although similarities exist in many characteristics among developing countries, a critical limitation is related to the external validity specifically, the ability to generalize our results outside Turkey.

Chapter 68
Trust, Perceived Benefit, and Purchase Intention in C2C E-Commerce:
An Empirical Examination in China

ABSTRACT

It is a class research question about how trust and perceived benefit affect consumers' purchase intentions. This research examines the relationship in a very different context: consumer-to-consumer (C2C) e-commerce in China. Specifically, this research empirically assesses the differences in effect size due to the change of context. First, a theoretical model linking trust, perceived benefit, and their antecedents to purchase intention is developed upon the literature. Then the model is evaluated using empirical data collected at Taobao, the largest C2C e-commerce website in China. Partial least squares based structural equation modeling (PLS-SEM) results strongly support the model and research hypotheses. A developing country context can indeed affect the strength of effect. These results contribute to the literature in that they provide new insights toward a more in-depth theoretical understanding. Meanwhile, they can also provide useful guidance for managers.

INTRODUCTION

The turn of the millennium is characterized by an extremely fast growth of the Internet. Since its inception in the early 1990s, the Internet has brought tremendous changes to virtually all aspects of human life (Bi et al., 2017, 2018; Civerchia, Bocchino, et al. 2017; Cheng et al 2018; Finogeev and Finogeev, 2017; Gholami, Taboun and Brennan, 2018; Gorkhali & Xu, 2016; Gürdür and Asplund, 2018; Kim 2017; Lai et al 2017; Li, Xu, & Zhao, 2018; Lu 2017; Peruzzini and Stjepandić, 2018; Tan, Jiang, Gu, 2017; Xiao et al 2014; Xu, He, & Li, 2014; Yang, Stankevicius, Marozas et al., 2018). Among all changes, e-commerce is obviously one of the most significant. E-commerce today has developed into a common, daily activity for consumers (Turban, King, Lee, & Viehland, 2002). The past two decades have witnessed numerous new technologies that enabled the deployment of a plethora of e-commerce websites such as Amazon and eBay. Since the Internet does not have a national or geographical boundary, businesses that provide e-commerce are enthusiastic about leveraging the opportunity to reach more customers, further reduce cost and improve profit.

Among all the interesting research questions, a crucial one has attracted many researchers' attention: What factors affect consumers' purchase behavior? It is a classic research question that dates back to the 1970s in marketing research. Built upon the Theory of Reasoned Action (TRA), marketing scholars have suggested that trust and perceived benefit significantly affect consumers' purchase intention, which in turn guides their purchase behaviors (Ajzen & Fishbein, 1980; Fishbein & Ajzen, 1975). As the Internet and e-commerce becomes increasingly popular and pervasive (Assarzadeh and Aberoumand, 2018; Cai et al 2014; Fan et al., 2014; Fang et al 2014; Li, Oikonomou, Tryfonas, et al., 2014; Liu et al., 2017; Lu 2018; Lu and Xu, 2018; Mao et al 2016; Qi et al 2017; Viriyasitavat and Hoonsopon, 2018; Wang, et al., 2014; Xu, 2011; Xu et al 2018; Yan, et al., 2018; Zhai et al 2016; Zheng et al 2014), information systems and information technology (IS/IT) researchers have shown that the same model is not confined to brick-and-mortar businesses, but also applies to e-commerce or online shopping (Kim, Ferrin, & Rao, 2008). There are conclusive evidences on how trust and perceived benefit affect purchase intention.

Will the relationships remain the same in a different context? Most extant studies were conducted in a developed country setting, where rules and regulations are well established, financial systems are mature, privacy protection is expected, and consumers are less concerned with security issues. In contrast, one cannot assume the same in a developing country context. Researchers have found China particularly interesting in this regard (Cui & Jiang, 2018; Li, 2013; Li & Zhou, 2013). China is a developing country, but its e-commerce growth rate is the fastest in the world. By 2013, the number of online shopping transactions in China exceeded 2.8 billion (iResearch, 2015). Accompanying with this fast growth rate though, is an increasingly severe concern of trust and security issues. Many sellers in China are small businesses or individuals without a strong brand or established credibility. News on security breach or privacy threat is commonly heard. Given such a vastly different context, naturally, the question is whether theoretical models based on TRA are still applicable.

A review of the literature shows that the answer to the question is mostly positive, but quantitative specifics are largely missing. Models based on TRA can explain consumers' purchase behaviors in a developing country context, but parameters such as antecedents and effect size may change. Unfortunately, very few studies have attempted to address the specifics. For example, studies have shown that trust and perceived benefit still affect purchase intention in a developing country context, but it is largely a myth how much effect change it will be when there is a context change. Will consumers in China value trust over perceived benefit or vice versa? There are more questions along the same line of thinking: What

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

is the impact of a developing country context on the relationship between trust and its antecedents, and perceived benefit and its antecedents? Does one antecedent have a stronger or weaker effect?

The purpose of this study is to explore for answers to these questions. Empirically validated answers can lead to interesting novel insights about a proven theoretical framework. Such insights can help further theoretical development, leading to a model that can better explain and predict consumers' purchase behaviors in a developing country. This study can potentially make a solid contribution to the literature. Meanwhile, insights obtained from this study can also help managers be more effective in managing e-commerce, particularly in China.

This paper is organized as follows. The next section reviews and synthesizes the extant literature to develop a theoretical model with research hypotheses. The discussion is focused on how effect size can be different in a developing country context. Empirical research design for this study is described next. The measurement instrument is also presented. Results are obtained and deliberated using the partial least squares based structural equation modeling (PLS-SEM) method. The paper concludes with a discussion on potential contributions to both the literature and practices. The limitation of this study and future research directions are also addressed.

THEORETICAL DEVELOPMENT AND RESEARCH HYPOTHESES

Theory of Reasoned Action (TRA) Theoretical Framework

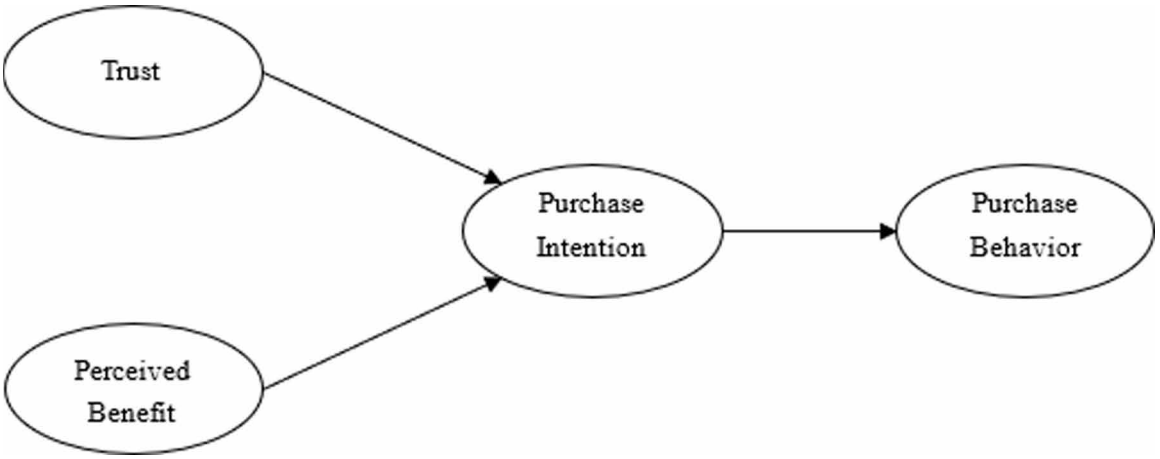
Consumer behaviors is a main research topic in the marketing field. Many research studies can trace their root back to Theory of Reasoned Action (TRA). TRA posits that behavioral intentions are immediate antecedents to behavior, and behavioral intentions are a function of information or beliefs about the likelihood that performing a particular behavior will lead to a specific outcome (Ajzen & Fishbein, 1980; Bai, 2018; Chong, et al., 2018; Fishbein & Ajzen, 1975). Researchers have used the TRA theoretical framework to study a variety of issues, for example, information technology acceptance or adoption (Venkatesh, Morris, Davis, & Davis, 2003). In the field of consumer behaviors, TRA states that consumers will assess benefits and risks associated with a purchase action, the assessment result will directly affect their purchase intention, which eventually determines whether they will conduct a purchase behavior (e.g., Jarvenpaa, Tractinsky, & Saarinen, 1999). Figure 1 summarizes the TRA theoretical framework for consumers' purchase behavior.

Developing Country Context

To date, a rich body of literature is available on consumer behavior using the TRA theoretical framework. On one direction, researchers have enriched the base model with the incorporation of antecedents. For example, many studies have identified different factors that affect consumers' Trust and Perceived Benefit (Sirdeshmukh, Singh, & Sabol, 2002). On another direction, numerous studies have taken the base model to different contexts to examine its validity and generalizability. For instance, some studies examined the model in an e-commerce context instead of physical stores (Hoffman, Novak, & Peralta, 1999; Lee & Turban, 2001). Studies have also looked at a Consumer-to-Consumer (C2C) context other than Business-to-Consumer (B2C) (Chen, Zhang, & Xu, 2009; Giraldi, Ceccacci, Bevilacqua, and Men-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. The base model: Consumers' purchase behavior based on TRA



goni, 2018; Kim et al., 2008; Li, Ye, Law, & Wang, 2010; Lu, Zhao, & Wang, 2010). In most cases, the TRA theoretical framework has proven its applicability.

To be effective, the base model must be "customized" to fit specific contexts. Many times the consideration of a specific context can be quite challenging. For example, Martinsons (2008) found that e-commerce in China bears the characteristics of relationship-based, hence studies need to incorporate such factors. But the unfortunate fact is that, up to date, such customization effort is rather *ad hoc*. Overall, there is a lack of systematic exploration on how contexts may affect researchers' model development and empirical results.

The context of China bears several interesting characteristics, and they will be carefully considered in this research study. Despite fast economy growth in the past several decades, China is still largely a developing country due to its large population. Generally, the literature has characterized developing countries as not having well-established financial and legal systems, and weak consumer privacy and rights protection. However, when the developing country is China, such a characterization may be an oversimplification or even a mischaracterization. For example, development and application of mobile Internet in China is by no means trailing, but to the contrary, leading developed nations in many ways (Su et al 2018). The continued high-speed economy growth in China is nothing short of miracle. This unusually long growth period has caused major changes in China. For instance, the financial system in China is a delicate mix of both a rigid banking system and a highly vigorous mobile payment system, e.g., Alipay. It will be a mistake for researchers with a developed country background to simplify the context as a "lagging-behind financial system." Another major factor is that one-child policy has been implemented in China for several decades, leading to a highly disturbing population structure in which a typical (extended) family is consisted of four grandparents, two parents, and one child. The implications are profound and multi-folded. For example, the only child of such an extended family often has enough financial resources at disposal, which usually lead to a high selectivity in his or her employment choices, making labor availability in China much more than a simple economics issue but also a societal and political issue. All in all, studies on consumers' purchase intention have not sufficiently addressed such a unique and challenging context.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

This research study starts with a base model derived from the literature. Then the model is expanded to include antecedents that are relevant to China. Specifically, the focus in on assessing the effect size. First of all, it is expected that the base model is applicable in China due to its wide generalizability: Perceived Benefit and Trust will affect consumers' Purchase Intention in a C2C setting (Kim et al., 2008; Li et al., 2010). However, the literature is yet to define whether the developing country context in China will make the effect of one factor stronger than the other or vice versa. Further, the specific context also demands a careful identification of relevant antecedents to these two factors. There potentially are many plausible antecedents to Trust and Perceived Benefit, which ones are more relevant in this specific context? Moreover, there is a lack of evidence on whether a developing country context will attenuate or strengthen the effect of certain antecedents. Therefore, a systematic exploration may answer these questions, and potentially make a significant contribution to both the literature and practices, which is exactly the purpose of this empirical study.

The Base Model

According to the extant literature, the base model should be applicable in the specific context of this study: C2C e-commerce in China. The base model, as illustrated in Figure 1, states that both Trust and Perceived Benefit have positive effect on Purchase Intention.

Purchase Intention

Purchase Intention refers to a consumer's willingness to commit to a buying transaction. In the context of online shopping, Purchase Intention represents the readiness of a consumer for an online transaction. In today's Internet environment, consumers use an e-commerce service provider's website to search and acquire information about products, and related services. Purchase Intention can be operationalized as the probability that a consumer will buy a certain product or service afterwards (Schlosser, White, & Lloyd, 2006).

C2C Trust, Perceived Benefit, and Purchase Intention

According to Merriam-Webster dictionary, trust is a "belief that someone or something is reliable, good, honest, effective, etc." Undoubtedly, trust plays a crucial role in e-commerce. Indeed, trust is a prerequisite for consumers to participate in online shopping. With trust, consumers are willing to proceed ahead with transaction even when there are uncertainties (McKnight, Choudhury, & Kacmar, 2002).

In the literature on online shopping and e-commerce, most studies on trust involve business-to-consumer (B2C) websites. This is understandable because most transactions happen in the context of B2C. However, consumer-to-consumer (C2C) websites are growing rapidly and gaining wide popularity, particularly in developing countries such as China (Chen, Zhang, Yuan, & Huang, 2007). Taobao, the largest C2C website in China, enjoyed a tremendous growth rate in the past several years. On a C2C website, consumers do not deal with a large business. Instead, a C2C website provides a platform for consumers to interact and transact with other businesses or sellers, often small in scale. Trust in this context involves not only the C2C website, but also information provided by sellers on the C2C website. Clearly, a lack of trust will prevent consumers from committing to online shopping (Hong, 2018; Jones & Leonard, 2008). Consumers evaluate online sellers for their ability to clearly describe products

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and services, to keep promises, and their goodwill to customer service (Ou, Pavlou, & Davison, 2014; Palvia, 2009). The level of trust clearly affects whether consumers will accept the C2C website and use it for transactions. In short, it is believed that a positive impact of trust on purchase intention still exists in a C2C context. It can be further argued that this relationship holds true regardless of developed or developing countries. It is stated as hypothesis H1a and fully expected to be confirmed empirically.

Hypothesis H1a*: Consumers' Trust on C2C e-commerce is positively related to their Purchase Intention*.

In the marketing literature, it is well documented that a consumer's buying behavior is closely related to benefit the consumer perceives. Perceived Benefit refers to value or functionality provided by a product or service that customers can gain by using it. In online shopping, such benefit may include not only the product or service itself, but also convenience, availability of choices, time or cost savings (Kim et al., 2008). Clearly, a higher level of Perceived Benefit will translate into a stronger Purchase Intention. If a consumer is satisfied with benefit provided by an e-commerce service provider, the consumer is likely to become a repeated customer. The opposite is also true, a lower level of Perceived Benefit will decrease the consumer's Purchase Intention, or even stop the consumer from coming back to an e-commerce service provider. In summary, a strong positive effect of Perceived Benefit on Purchase Intention exists in a C2C context, also regardless of developed or developing countries. This is stated as research hypothesis H1b.

Hypothesis H1b: *Consumers' Perceived Benefit is positively related to their Purchase Intention*.

Next, the specific context in which this research is conducted is carefully examined. Hypotheses H1a and H1b state that both Trust and Perceived Benefit have positive impact on Purchase Intention. It is reasonable to argue that Perceived Benefit has a much larger effect size than that of Trust, due to characteristics of C2C e-commerce in China. In this specific context, the role of Trust is more like an order qualifier while Perceived Benefit is an order winner in today's e-commerce in China. Back in early 2000's, e-commerce development in China was slow due to many obstacles (Wong, Yen, & Fang, 2004). More than one decade later, e-commerce has become a norm in ordinary Chinese people's life. According to Deloitte Research (2016), the transaction scale of online retail market reached RMB 3.8 trillion in 2015, representing 12.6% of total retail sales in China. Using C2C website such as Taobao has become a part of Chinese people's daily life. During this process, many C2C websites have emerged and disappeared. The remaining providers must have survived in competition, and earned consumers' trust. To that extent, Trust is a qualifier, or a threshold of the game. Without Trust, consumers will not transact on a C2C website. But once the trustworthiness of a C2C website has been established, its effect on consumers' Purchase Intention becomes rather small. Perceived Benefit, on the other side, becomes the major driving force behind consumers' online activities (Wang, Po Lo, Chi, & Yang, 2004). The above arguments are summarized as research hypothesis H1c.

Hypothesis H1c: *In a developing country context, Perceived Benefit has a much larger effect than that of Trust on consumers' Purchase Intention*.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Antecedents of C2C Trust

The base model is then expanded to include antecedents for both Trust and Perceived Benefit. There can be many different antecedents. The identification of such antecedents is largely context dependent. For Trust, Perceived Risk is identified as one important antecedent (Lu et al., 2010). Perceived Risk is commonly defined as the felt uncertainty regarding possible negative consequences of using a product or service (Featherman & Pavlou, 2003). It is "the expectation of losses associated with purchase and acts as an inhibitor to purchase behavior" (Peter & Ryan, 1976). Clearly, Perceived Risk can have a strong negative impact on consumers' trust on a C2C e-commerce service provider. Particularly, online shopping is different from traditional shopping in that consumers usually interact with a website but not a brick-and-mortar store. This lack of visibility and transparency may cause fear against online shopping. Consumers simply will stop online shopping if Perceived Risk is too high. Such risks include but are not limited to: product risk (e.g., inaccurate product description, defective products); financial risk (e.g., fraud, ability to return and refund). In physical stores, consumers can touch, feel, or even try a product before committing to a buying decision. In online shopping, consumers must rely on information provided online, e.g., texts, pictures, videos. Their evaluation of the product becomes nothing more than a speculation. Providing personal information to a seller or a website is also a highly risky action, which is generally an irreversible action, and can lead to serious consequences such as ID theft or funds loss (Araujo & Araujo, 2003). A delivery time lag also exacerbates the perception of risks. As a result, the level of Perceived Risk directly contributes to the level of Trust consumers may have for a C2C e-commerce website or service provider (Olivero & Lunt, 2004). This is stated as hypothesis H2a.

Hypothesis H2a: *Consumers' Perceived Risk is negatively related to their trust level in C2C e-commerce.*

Perceived Security Protection is another important antecedent to C2C Trust. Perceived Security Protection refers to consumers' assessment of a C2C website whether it has deployed satisfying security measures. Such security requirements include authentication of transactions, payment security, and confidentiality of transactions and personal information (Li et al., 2010; Zhang, Bian, & Zhu, 2013). Specifically, a C2C website needs to provide a real name authentication system through ID card, credit card, or other mechanisms, so that consumers are confident that they are dealing with legitimate parties. Once fraudulent activities are detected, a consumer's interest can be protected by informing the police or relevant government agencies. A legitimate and independent third-party payment system, usually endorsed by banks in China, is also vital because consumers have a high level of trust in banks in China. Such a system can ensure consumers that the payment mechanism is safe and convenient. In short, hypothesis H2b states:

Hypothesis H2b: *Consumers' Perceived Security Protection is positively related to their Trust in C2C e-commerce.*

Perceived Privacy Protection deals with consumers' perception of how likely their personal information will be leaked to unauthorized parties. During an online shopping transaction, a seller needs to collect a buyer's name, address, phone number, and other relevant information. While such information should be kept strictly confidential, some sellers may sell this information for profit to marketers or even spammers. Consumers then have to face spam calls or even credit card fraud. To gain consumers' trust,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

a C2C service provider must demonstrate to consumers that their confidential information is indeed kept confidential. On the other hand, a lack of privacy protection will certainly lead to a lower level of trust (Kim et al., 2008). The above is stated as hypothesis H2c.

Hypothesis H2c: *Consumers' Perceived Privacy Protection is positively related to their Trust in C2C e-commerce.*

Among the three antecedents, Perceived Security Protection should have the largest effect on Trust in China. In a developing country, specifically, China, privacy is still a relative new issue. According to the national culture literature (Hofstede & Peterson, 2000), Chinese people do not have as strong a sense about privacy as Western people. Therefore, it is conceivable that Perceived Privacy Protection will not play as important a role as other factors. When compared with Perceived Risk, Perceived Security Protection is more important to Chinese people. As a nation with a long history of monarchy political system, Chinese people has the tendency to rely on authorities to protect them. To most Chinese people, product or financial risk is manageable but it is extremely difficult to deal with security protection breach without authority's intervention. Therefore, it is expected that Chinese people would place more weight on Perceived Security Protection. This is stated as research hypothesis H2d.

Hypothesis H2d: *In a developing country context, Perceived Security Protection has the largest effect on C2C Trust among all three antecedents.*

Antecedents of Perceived Benefit

Similarly, the developing country context of China is considered in identifying antecedents for Perceived Benefit. According to the marketing literature, consumers' experience has a significant impact on how their perceptions form (Jones & Leonard, 2008; Kim et al., 2008). In the context of online shopping, the experience is largely determined by two quality factors: Website Quality, and Decision Quality.

In online shopping, a website is virtually the only interface consumers interact with all the time. There is little doubt that Website Quality hence has a significant impact on consumers' perception formation. For a website that is easy to navigate, filled with up-to-date information, consumers can be more confident that the website is well maintained and the staff behind the website is strong and capable. This will easily translate into confidence of products and services provided. The perception is likely that the service provider has acquired a sufficient amount and variety of products to satisfy consumer requirements. When a website provides valuable and sufficient information, consumers no longer need to search across multiple websites. This equates to convenience and time savings, a significant benefit for consumers (Jones & Leonard, 2008; McKnight et al., 2002). In short, hypothesis H3a states:

Hypothesis H3a: *Website Quality is positively related to consumers' Perceived Benefit of C2C e-commerce.*

Another important antecedent is Decision Quality. Decision Quality refers to the degree of match or fit between different kind of customers' preferences and differentiated products. A higher Decision Quality means that consumers believe that a transaction is valuable, worthwhile, and satisfying. In other words, Decision Quality leads to Perceived Benefit (Zha, Li, & Yan, 2013). This is stated as research hypothesis H3b.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypothesis H3b: *Decision Quality is positively related to consumers' Perceived Benefit of C2C e-commerce.*

It can be argued that Website Quality has a much larger effect on Perceived Benefit than that of Decision Quality. According to Bai, Law, and Wen (2008), Chinese online visitors value Website Quality very much to the extent that it drives customer satisfaction and subsequently, purchase intention. The significance of Website Quality becomes apparent when one considers the developmental trajectory of C2C e-commerce in China. Many have characterized e-commerce growth in the past decade as "wild" or even "barbarian." Numerous e-commerce websites emerged and disappeared. Unlike traditional brick-and-mortar businesses who have spent tremendous amount to establish their brand images, almost all e-commerce websites in China are "new" because none of them had a history longer than 20 years. Chinese online shoppers very much can only rely on the web interface to evaluate an e-commerce provider. This website interaction experience largely defines consumers' perception. On the other side, while it is a legitimate argument that the brand image or reputation of a supplier shapes consumers' perception, the influence is in fact minimal in China. Except a few products such as cell phones, most manufacturers are small to medium sized businesses who do not have a strong brand. Their influence, if any, is further dampened due to the large disintermediation effect of C2C e-commerce website. Essentially, Website Quality becomes the most prominent factor in determining consumers' Perceived Benefit (hypothesis H3c).

Hypothesis H3c: *Among the two antecedents, Website Quality has a much larger effect on Perceived Benefit in a developing country C2C e-commerce context.*

Putting all research hypotheses together, the result is a structural model that links antecedents to C2C Trust and Perceived Benefit, and subsequently, Purchase Intention. In Figure 2, bold factors represent having a stronger effect.

EMPIRICAL RESEARCH DESIGN

Empirical Research Setting

For this study, empirical data was collected using online survey from college students in China. An online survey questionnaire was implemented and then distributed to students via email. A total of 403 students were invited and given a two-week time window to complete the survey. The student respondents were also encouraged to share the online survey with their acquaintances, which led to more responses. The majority (>95%) of the survey respondents are college students. With active follow up activities such as reminder emails, the final sample contained 236 valid responses. The response rate is a highly respectable 58.6%.

When college students are used for empirical data collection, the concern is whether their responses represent the population of interest, which may challenge the validity and generalizability of findings. It is a serious concern for studies conducted in a developed country context. In this study though, it is likely the opposite due to the specific characteristics of China: College students well represent the population of C2C e-commerce users. First, Internet is predominantly a young people thing in China. Young people, particularly college students, are pioneers of Internet adoption and active users. This fact

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

largely alleviated the concern that college students are a biased representation of the population of interest. Second, in studies conducted in developed countries, college students are a biased sample because they often have less purchasing power. This is not true in China due to the aforementioned one-child policy. The policy has effectively concentrated wealth of two generations to the only child of a family, making college students not a "poor" group most of the time. In fact, college students are very active in online shopping. In China, many major Internet companies started next to college campuses. For example, meituan.com and ele.me, two Internet companies who have successfully established their reputation as food delivery service providers, both started near college campuses. The latest example is OFO, a bike sharing company. In its early stage, OFO strictly focused on college campuses. According to a reported published online by eMarketer.com, over 60% of Taobao mobile app users are under the age of 30. Given the wealth college students possess and time they have for the Internet, the college student sample actually reflects the population of interest very well (Jones & Leonard, 2008; McKnight et al., 2002).

Sample Characteristics

Table 1 below presents descriptive statistics of the samples obtained. The demographics information fits college students precisely. It is worth noting that the majority of respondents have rich experiences with the Internet and online shopping. Therefore, analyzing this sample can lead to valuable insights.

Table 1. Descriptive statistics

Classification	Frequency (%)
Gender	
Male	110(46.61%)
Female	126 (53.39%)
Age	
Under 18	9 (3.81%)
18-30	207 (87.71%)
31-40	16 (6.78%)
41-50	2 (0.85%)
Over 50	2 (0.85%)
Education level (highest level of education completed)	
High school and below	16 (6.78%)
Secondary Technical school	10 (4.24%)
College	38 (16.1%)
Undergraduate	142 (60.17%)
Postgraduate	30 (12.71%)
Experience in using the Internet	
<1 year	8 (3.39%)
1-3 year	53 (22.46%)
3-5 year	74 (31.36%)
>5 year	101 (42.8%)
Experience in shopping online	
<1 year	36 (15.255%)
1-3 year	106 (4.92%)
3-5 year	49 (20.76%)
>5 year	45 (19.07%)
>5	

Measurement Instrument

The standard procedure was followed to develop and validate a measurement instrument for the variables. Existing scales generally show better reliability and validity because they have been validated by past

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

empirical studies. In this research, all constructs have existing scales in the literature. The items were adapted to suite the context of this research. For example, Taobao in China is the C2C e-commerce website selected. So the generic phrase of "Website" in the original scales was replaced by "Taobao" wherever appropriate.

Since the survey was conducted in a non-English speaking country, the measurement instrument items were carefully translated into Chinese. Again, the standard procedure was followed to have a third party back translate the Chinese items into English. A thorough examination was performed to ensure that there was no ambiguity or errors.

Table 2 presents the measurement instrument for all variables. All items used the same seven-point Likert scale (1=Disagree strongly, 2=Disagree, 3=Disagree somewhat, 4=Neutral, 5=Agree somewhat, 6=Agree, 7=Agree strongly, and N=No response), which captures more variation than a five-point scale (Ahire, Golhar, & Waller, 1996). Using the same scale also reduces the burden on respondents, which motivates a higher response rate. Note that several items are reverse-coded to detect automatic responses. They were reversed back in data analysis.

RESULTS

Partial Least Squares

Partial least squares (PLS) is an advanced statistical method that "facilitates testing of the psychometric properties of the scales used to measure a variable, as well as estimating the parameters of a structural model – that is, the magnitude and direction of the relationships among the model variables". PLS is an effective multivariate technique that has been widely applied in information systems and information technology research. Compared to the conventional covariance-based technique, PLS has the advantage of being less demanding on data. PLS can work with small data sets with many missing values. In addition, with a large sample size, PLS can leverage the statistical power to reach strong conclusions (Marcoulides & Saunders, 2006).
