Table of Contents

Preface xxvi

Volume I

Section 1
Fundamental Concepts and Theories

Chapter 1
New Economy, E-Commerce Businesses, and E-Businesses: Types, Similarities, and Differences 1
Duygu Toplu Yaşlıoğlu, Istanbul University, Turkey

Chapter 2
The Affective Domain of E-Commerce 19
Vildan Ateş, Ankara Yıldırım Beyazıt University, Turkey

Chapter 3
Mobile Social Commerce 40
Christine Balague, Institut Mines Telecom, France
Zhenzhen Zhao, ISC Paris Business School, France

Chapter 4
Security Issues in E-Commerce 53
Arram Sriram, Anurag Group of Institutions, India
Adiraju Prashantha Rao, Anurag Group of Institutions, India

Chapter 5
Electronic Payment Systems in Electronic Commerce 82
Rana Atabay Kuscu, Istanbul Medipol University, Turkey
Yasemin Cicekcisoy, Istanbul Halic University, Turkey
Umit Bozoklu, Istanbul Gedik University, Turkey

Chapter 6
Infrastructural Drivers of Online Shopping: An International Perspective 109
Syed Akhter, Marquette University, Milwaukee, WI, USA

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 7
Development of E-Commerce: Factors Influencing Online Impulse Shopping in China..... 122
Umair Akram, School of Economics and Management, Beijing University of Posts and Telecommunications, Beijing, China
Muhammad Kaleem Khan, School of Economics and Management, Beijing University of Posts and Telecommunications, Beijing, China
Peng Hui, School of Economics and Management, Beijing University of Posts and Telecommunications, Beijing, China
Yasir Tanveer, School of Economics and Management, Beijing University of Posts and Telecommunications, Beijing, China
Zubair Akram, School of Management and Economics, Beijing Institute of Technology, Beijing, China

Chapter 8
Influences and Intention of Consumer's Online Shopping Decision: Jordan as a Case 143
Radwan Moh'd Al-Dwairi, Department of MIS, Faculty of Information Technology and Computer Sciences, Yarmouk University, Irbid, Jordan
Murad Al Azzam, Department of MIS, Faculty of Information Technology and Computer Sciences, Yarmouk University, Irbid, Jordan

Section 2
Development and Design Methodologies

Chapter 9
E-Commerce Business Model..... 160
Durga Patel, University Institute of Technology, India
Sachin Goyal, University Institute of Technology, India
Ratish Agarwal, University Institute of Technology, India

Chapter 10
Strategizing SCM-M Interface Using DeLone and McLean Model of IS Success and Fuzzy Cognitive Maps: Perspectives on E-Commerce Success 180
Shekhar Shukla, S.P. Jain Institute of Management and Research, Mumbai, India
B.K. Mohanty, IIM Lucknow, Uttar Pradesh, India
Ashwani Kumar, IIM Lucknow, Uttar Pradesh, India

Chapter 11
Strategies to Predict E-Commerce Inventory and Order Planning 212
Mohammad Anwar Rahman, Central Connecticut State University, New Britain, CN, USA
Laura Casanovas, Central Connecticut State University, New Britain, CN, USA

Chapter 12
The Role of Social Commerce Components on the Consumer Decision-Making Process 227
Saleh Mohammed Kutabish, University of Minho, Portugal
Ana Maria Soares, School of Economics and Management, University of Minho, Portugal

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 13
Understanding User Social Commerce Usage Intention: A Stimulus-Organism-Response Perspective 240
Tao Zhou, School of Management, Hangzhou Dianzi University, Hangzhou, China

Chapter 14
Consumer Protection in Online Shopping: An Investigation of Virtual Credit Card Awareness in Turkey 257
Emre Yildirim, Sakarya University, Turkey

Chapter 15
Understanding Country Level Adoption of E-Commerce: A Theoretical Model Including Technological, Institutional, and Cultural Factors 275
Punit Ahluwalia, University of Texas Rio Grande Valley, Edinburg, USA
Mohammad I. Merhi, Indiana University South Bend, South Bend, USA

Chapter 16
A Cloud Computing-Based Model of E-Commerce Adoption for Developing Countries 300
Ghada Refaat El Said, Management Information Systems Department, Future University in Egypt (FUE), New Cairo, Egypt

Chapter 17
The Moderating Effects of Gender on E-Commerce Systems Adoption Factors 319
Frederick Pobee, University of Pécs, Hungary
Daniel Opoku, School of Business, Department of Human Resource, University of Education, Winneba, Ghana

Chapter 18
Study on E-Commerce Adoption in SMEs Under the Institutional Perspective: The Case of Saudi Arabia 341
Almaaf Bader Ali A, Nanjing University of Aeronautics and Astronautics, Nanjing, China
Jian-Jun Miao, College of Economics and Management, Nanjing University of Aeronautics and Astronautics, Nanjing, China
Quang Dung Tran, National University of Civil Engineering, Hanoi, Vietnam

Chapter 19
An Analysis of the Factors Influencing the Adoption of Online Shopping 363
Ali Tarhini, Sultan Qaboos University, Muscat, Oman
Ali Abdallah Alalwan, Al-Balqa' Applied University, Salt, Jordan
Nabeel Al-Qirim, United Arab Emirates University, Al-Ain, United Arab Emirates
Raed Algharabat, The University of Jordan, Amman, Jordan
Ra'ed Masa'deh, The University of Jordan, Amman, Jordan

Chapter 20
Design Methodology for Effective User Interface Design for E-Commerce Applications 385
Namratha Birudaraju, Anurag Group of Institutions, India
Adiraju Prasanth Rao, Anurag Group of Institutions, India

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 21
A Framework to Improve Performance of E-Commerce Websites 413
G. Sreedhar, Rashtriya Sanskrit Vidyapeetha (Deemed University), India

Chapter 22
Creating Utilitarian and Hedonic Value from Website Quality and Online Retail Performance 429
Edward Shih-Tse Wang, National Chung Hsing University, Taichung, Taiwan

Chapter 23
Web Content Analysis of Online Grocery Shopping Web Sites in India..... 443
Tanushri Banerjee, School of Management, Pandit Deendayal Petroleum University, Gandhinagar, India
Arindam Banerjee, Professor of Marketing, Indian Institute of Management, Ahmedabad, India

Chapter 24
Online Store Attribute Preferences: A Gender Based Perspective and MCDM Approach 457
Praveen Ranjan Srivastava, Indian Institute of Management (IIM) Rohtak Campus, Sunaria (Rohtak), 124001, India
Anand Sharma, Indian Institute of Management (IIM) Rohtak Campus, Sunaria (Rohtak), 124001, India
Rama Shankar Yadav, Indian Institute of Management (IIM) Rohtak Campus, Sunaria (Rohtak), 124001, India
Satyendra Kumar Sharma, BITS Pilani, Rajasthan, India
Inderjeet Kaur, Indian Institute of Management (IIM) Rohtak Campus, Sunaria (Rohtak), 124001, India

Chapter 25
Analysing Critical Success Factors for Supporting Online Shopping 473
Maria Leonilde R. Varela, Department of Production and Systems, School of Engineering, University of Minho, Guimarães, Portugal
Goran D. Putnik, Department of Production and Systems, School of Engineering, University of Minho, Guimarães, Portugal
Maria do Sameiro Carvalho, Department of Production and Systems, School of Engineering, University of Minho, Guimarães, Portugal
Luís Ferreira, Polytechnic Institute of Cávado and Ave, Campus do IPCA, Barcelos, Portugal
Maria Manuela Cruz-Cunha, Polytechnic Institute of Cávado and Ave, Campus do IPCA, Barcelos, Portugal & Algoritmi Research Centre, University of Minho, Portugal
V. K. Manupati, School of Mechanical Engineering, Division of Manufacturing, VIT University, Vellore, India
K. Manoj, School of Mechanical Engineering, Division of Manufacturing, VIT University, Vellore, India

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 26
Exploring the Factors Influencing Customers Purchase Intention in Online Shopping 492
Fahima Khanam, University of Dhaka, Dhaka, Bangladesh

Chapter 27
Best Customer Experience in E-Retailing: A Knowledge-Based Empirical Model..... 507
Tahir Iqbal, Imam Abdulrahman Bin Faisal University, Saudi Arabia

Chapter 28
The Online Reviews' Effects on Internet Consumer Behavior: An Exploratory Study..... 525
Mingli Zhang, Yanshan University, School of Economics and Management, Qinhuangdao, China
Suyun Ding, Yanshan University, School of Economics and Management, Qinhuangdao, China
Yuanwei Bian, Yanshan University, School of Economics and Management, Qinhuangdao, China

Chapter 29
Predicting Shoppers' Continuous Buying Intention Using Mobile Apps..... 538
Sanjeev Prashar, Indian Institute of Management (IIM) Raipur, Raipur, India
Priyanka Gupta, Indian Institute of Management (IIM) Raipur, Raipur, India
Chandan Parsad, Rajagiri Business School, Kochi, India
T. Sai Vijay, Institute of Management Technology (IMT) Nagpur, Nagpur, India

Chapter 30
Structural Equation Modelling of the Factors Influencing the Adoption of E-Commerce in Saudi Arabia: Study on Online Shoppers 556
Abdullah Saleh Alqahtani, Deanship of Common First Year, Self-development Skills Department, King Saud University, Riyadh, Saudi Arabia
Robert Goodwin, School of Computer Science, Engineering and Mathematics, Flinders University, Adelaide, Australia
Denise de Vries, Flinders University, Adelaide, Australia

Chapter 31
Designing Indulgent Interaction: Luxury Fashion, M-Commerce, and Übermensch 580
Christopher J. Parker, The University of Manchester, UK
Stephen A. Doyle, The University of Manchester, UK

Section 3
Tools and Technologies

Chapter 32
Electronic Commerce and Decision Support Systems: Theories and Applications 602
Kijpokin Kasemsap, Suan Sunandha Rajabhat University, Thailand

Chapter 33
Resources and Value Co-Creation in Social Commerce: Evidence From Business Models in a Developing Economy – A Viewpoint for Future Research..... 621
Edward Entee, Univeristy of Ghana, Ghana

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Volume II

Chapter 34
A Novel Fuzzy Integrated Customer Needs Prioritization Software Tool for Effective Design of Online Shopping Websites 634
Ashish K. Sharma, Manoharbhai Patel Institute of Engineering and Technology, Department of Computer Technology, Gondia, India
Sunanda Khandait, KDK College of Engineering, Department of Information Technology, Nagpur, India

Chapter 35
The Use of Written Descriptions and 2D Images as Cues for Tactile Information in Online Shopping 656
Flor Morton, Universidad de Monterrey, Mexico

Chapter 36
Exploring the Role of E-Servicescape Dimensions on Customer Online Shopping: A Stimulus-Organism-Response Paradigm 675
Rohit Yadav, Faculty of Management Studies, Amity School of Business, Amity University, Noida, India
Tripti Mahara, Institute of Management, Christ University, Bengaluru, India

Chapter 37
Experiencing Commercial Videos for Online Shopping: A Cross-Cultural User's Design Approach 699
Jose Cañas-Bajo, Aalto University, Finland
Johanna Silvennoinen, University of Jyväskylä, Finland

Chapter 38
Gamification in E-Commerce: Enhancing Digital Customer Engagement Through Game Elements 724
Farid Huseynov, Gebze Technical University, Turkey

Chapter 39
An Exploration of the Impact of Virtual Reality Interfaces on Online Shopping 742
Wen-Chin Hsu, Dept. of Information Management, National Central University, Taoyuan City, Taiwan
Po-Han Chen, Dept. of Information Management, National Central University, Taoyuan City, Taiwan
Chung-Yang Chen, Dept. of Information Management, National Central University, Taoyuan City, Taiwan

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 40
Can Virtual Customer Service Agents Improve Consumers' Online Experiences? The Role of Hedonic Dimensions 764
Ana Maria Soares, School of Economics and Management, University of Minho, Portugal
José Carlos M. R. Pinho, University of Minho, Portugal
Teresa Heath, University of Minho, Portugal
António Alves, University of Minho, Portugal

Chapter 41
Determinates of Live Support Chat in Organizational Intranets: An Empirical Study in Kuwait 781
Ahmed Elmorshidy, Gulf University for Science and Technology, Mubarak Al-Abdullah, Kuwait

Chapter 42
Mobile Commerce Technologies and Management 802
Kijpokin Kasemsap, Suan Sunandha Rajabhat University, Thailand

Chapter 43
The Impact of Emergent Technologies in the Evolutionary Path for M-Commerce 824
Justino Lourenço, Polytechnic Institute of Gaya, Portugal
Fernando Almeida, Polytechnic Institute of Gaya, Portugal

Chapter 44
Secure Payment Modes Technology for E-Commerce Applications 845
Niteesha Sharma, Anurag Group of Institutions, India
Adiraju Rao Prashanth, Anurag Group of Institutions, India

Chapter 45
Predictors of the Continued Adoption of WECHAT Mobile Payment 860
Isaac Kofi Mensah, School of Economics and Management, Jiangxi University of Science and Technology, Ganzhou, China

Chapter 46
Enhancing Online Repurchase Intention via Application of Big Data Analytics in E-Commerce 885
Steven Chan Siang Hui, Anglia Ruskin University, UK
Omkar Dastane, FTMS College, Malaysia
Zainudin Johari, FTMS College, Malaysia
Mardeni Roslee, Multimedia University, Malaysia

Chapter 47
The Role of Reputation on Trust and Loyalty: A Cross-Cultural Analysis of Tablet E-Tailing 925
Sunday Adewale Olaleye, University of Oulu, Oulu, Finland
Jari Salo, University of Helsinki, Helsinki, Finland
Dandison C. Ukpabi, University of Jyväskylä, Jyväskylä, Finland

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 48
Clustering E-Shoppers on the Basis of Shopping Values and Web Characteristics 941
Sanjeev Prashar, Indian Institute of Management Raipur, Raipur, India
Sai Vijay Tata, Indian Institute of Management Ranchi, Ranchi, India
Chandan Parsad, Rajagiri Centre for Business Studies, Kochi, India
Abhishek Banerjee, Indian Institute of Management Raipur, Raipur, India
Nikhil Sahakari, Indian Institute of Management Raipur, Raipur, India
Subham Chatterjee, Indian Institute of Management Raipur, Raipur, India

Chapter 49
Adoption of Online Subscription Beauty Boxes: A Behavioural Reasoning Theory (BRT) Perspective 958
Brijesh Sivathanu, Symbiosis Centre for Information Technology, Symbiosis International University, Pune, India

Chapter 50
Understanding Vietnamese Consumer Intention to Use Online Retailer Websites: Application of the Extended Technology Acceptance Model..... 984
A. F. M. Jalal Ahamed, University of Skövde, Sweden
Yam Limbu, Feliciano School of Business, Montclair State University, USA
Long Pham, School of Management, University of Louisiana at Monroe, USA & Department of Economics and Management, Thuyloi University, Hanoi, Vietnam
Ha Van Nguyen, Faculty of Business Administration, Banking Academy, Hanoi, Vietnam

Section 4
Utilization and Applications

Chapter 51
Reverse Logistics in E-Retaling..... 1001
Senem Ergan, Namık Kemal University, Turkey
Ayşe Akyol, Trakya University, Turkey

Chapter 52
Evaluating E-Commerce-Related Distribution and Warehousing in Terms of Sustainability..... 1028
Yeliz Demirkıran, Yaşar University, Turkey
Ikbal Ece Dizbay, Yaşar University, Turkey

Chapter 53
The Influence of Enjoyment Factor Toward the Acceptance of Social Commerce..... 1061
Alaa M. Momani, Faculty of Computer and Information Technology, Al-Madinah International University, Shah Alam, Malaysia
Wael M. Yafooz, Al-Madinah International University, Shah Alam, Malaysia
Mamoun M. Jamous, Faculty of Computer and Information Technology, Al-Madinah International University, Shah Alam, Malaysia

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 54
The Effects of Social Commerce Utilization on Business Performance: A Study of Hotels in Lebanon 1073
Firas Mohamad Halawani, International Tourism and Hospitality College at Riyadh, Lincoln College International (LCI), Saudi Arabia
Patrick C.H. Soh, Multimedia University, Cyberjaya, Malaysia
Yahya Mohamad Halawani, International Tourism and Hospitality College at Riyadh, Lincoln College International (LCI), Saudi Arabia

Chapter 55
E-Commerce Security Research in Big Data Environment 1100
Mei Zhang, School of Information, GUI Zhou University of Finance and Economics, Guiyang, China
Huan Liu, School of Information, GUI Zhou University of Finance and Economics, Guiyang, China
Jinghua Wen, School of Information, GUI Zhou University of Finance and Economics, Guiyang, China

Chapter 56
Exploring the Influence of Live Streaming in Mobile Commerce on Adoption Intention From a Social Presence Perspective 1115
Zixi Liu, Chuzhou Vocational and Technical College, China
Jian Yang, Chuzhou Vocational and Technical College, China
Lin Ling, Chuzhou Vocational and Technical College, China

Chapter 57
A Study on Performance of E-Commerce Web Applications 1136
Sreedhar G, Rashtriya Sanskrit Vidyapeetha (Deemed University), India

Chapter 58
Difficulty in Transition: Study on Hindrances in Online Shopping for Potential Shoppers 1144
Chand Prakash Saini, SGT University Gurugram, India

Chapter 59
Influence Factors of Online Shopping Food Quality Performance Considering the Relationship Quality 1157
Xiaoping Li, Jiangsu University of Science and Technology, Zhen Jiang, China
Lijuan Xie, Jiangsu University of Science and Technology, Zhen Jiang, China
Lan Xu, Jiangsu University of Science and Technology, Zhen Jiang, China

Chapter 60
Relationships Among Dimensions of Online Second-Hand Shopping, Satisfaction, and Repurchase Intention 1169
Murali Swapana, VIT Business School, VIT University, Vellore, India
Chandrasekaran Padmavathy, VIT Business School, VIT University, Vellore, India

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 61
Advantages and Obstacles of Electronic Commerce in Sports Footwear 1182
Blaženka Knežević, Faculty of Economics and Business, University of Zagreb, Zagreb, Croatia
Boris Šantić, First School of Economics Zagreb, Zagreb, Croatia
Ivan Novak, Faculty of Textile Technology, University of Zagreb, Zagreb, Croatia

Chapter 62
Consumer Shopping Orientations and Online Purchases of Rural Tourism Services 1203
Aleksandar Grubor, Faculty of Economics, University of Novi Sad, Serbia
Nenad Djokic, Faculty of Economics, University of Novi Sad, Serbia

Chapter 63
Enhancing Calculative Commitment and Customer Loyalty Through Online Relationship Marketing: The Mediating Role of Online Trust 1221
Sheena Lovia Boateng, Business School, University of Ghana, Ghana

Chapter 64
Hedonic and Utilitarian Values Behind Engagement of Online Consumers 1242
Farrah Zeba, ICFAI Business School (IBS), IFHE University (Deemed), India
Musarrat Shaheen, ICFAI Business School (IBS), IFHE University (Deemed), India
Raveesh Krishnankutty, Rajagiri Business School, India

Chapter 65
Men vs. Women: Study of Online Shopping Habits and Factors Influencing Buying Decisions in Bahrain 1264
Ali Hussein Zolait, University of Bahrain, Sakhir, Bahrain
Safeya Mohamed Isa, University of Bahrain, Sakhir, Bahrain
Hala Mahmood Ali, University of Bahrain, Sakhir, Bahrain
Veera Pandiyan Kaliani Sundram, Universiti Teknologi MARA, Shah Alam, Malaysia

Chapter 66
Antecedents of Social Commerce Adoption in Developing Countries: An Empirical Study 1278
Felix Nti Koranteng, University of Education, Winneba, Ghana
Richard Boateng, University of Ghana, Ghana
Richard Apau, Kwame Nkrumah University of Science and Technology, Ghana

Volume III

Chapter 67
Exploring Supportive and Deterrent Factors on Online Shopping in a Developing Country 1290
Tolga Pusatli, Cankaya University, Turkey
Ibrahim Akman, Atilim University, Turkey

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 68
Trust, Perceived Benefit, and Purchase Intention in C2C E-Commerce: An Empirical Examination in China 1313
Shukuan Zhao, Jilin University, Changchun, China
Yiwen Fang, Jilin University, Changchun, China
Weiyong Zhang, Old Dominion University, Norfolk, USA
Hong Jiang, Jilin University, Changchun, China

Chapter 69
What Makes Customers Repurchase Grocery Products from Online Stores in Korea 1339
Jin Yong Park, Konkuk School of Business, Seoul, South Korea
Dhanabalan Thangam, Acharya Institute of Graduate Studies, Banglore, India

Chapter 70
Understanding Egyptian Consumers' Intentions in Online Shopping 1357
Reham I. Elseidi, Ain Shams University, Faculty of Commerce, Business Department, Cairo, Egypt, & Badr University in Cairo, Cairo, Egypt

Chapter 71
Exploring Online Marketing Adoption Factors Among Used Car Sellers in Ghana 1377
Masud Ibrahim, University of Education, Winneba, Ghana
Anthony' Freeman Mensah, University of Education, Winneba, Ghana
Frederick Asare, Kumasi Technical University, Kumasi, Ghana

Section 5
Organizational and Social Implications

Chapter 72
Examination of the Extent and Effects of Strategic Management on E-Commerce Companies 1392
Zafer Adiguzel, Istanbul Medipol University, Turkey

Chapter 73
Examination of Effects of Competitive Strategies on the E-Commerce Companies in Terms of Achieving Sustainable Competitive Advantage 1419
Zafer Adiguzel, Istanbul Medipol University, Turkey

Chapter 74
Impact of E-Commerce on Agricultural Business Success 1452
Carla Sofia Vicente Negrão, University of Coimbra, Portugal

Chapter 75
Impact of Product Presentation on Purchase Intention: Moderating Role of Mood in Online Shopping of Lifestyle Products 1477
Devkant Kala, University of Petroleum and Energy Studies, India
D. S. Chaubey, Uttaranchal University, India

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 76
Millennials Consumers' Behaviors between Trends and Experiments 1492
Muhammad Anshari, Universiti Brunei Darussalam, Gadong, Brunei Darussalam
Yabit Alas, Universiti Brunei Darussalam, Gadong, Brunei Darussalam
Abdur Razzaq, Universitas Islam Negeri Raden Fatah Palembang, South Sumatra, Indonesia
Masitah Shahrill, Universiti Brunei Darussalam, Gadong, Brunei Darussalam
Syamimi Ariff Lim, Universiti Brunei Darussalam, Gadong, Brunei Darussalam

Chapter 77
Impact of Mood of the Millennial Customers on Purchase of Apparels Online 1509
Anusha Thakur, Stellarix Consultancy Services, India

Chapter 78
Components of Consumer Factor and Its Influence on Attitude of the Student Online Shopping Community: Consumer Factor and Its Influence on Attitude 1530
R.Rajendra Kumar, Research Scholar, Anna University, Chennai, India

Chapter 79
Study of Emotional Factors Influencing Professionals' Adoption to E-Payment in Sri Lanka 1548
Damith Dhanushka De Silva, Uva Wellassa University of Sri Lanka, Sri Lanka
Jayaranjani Sutha, Uva Wellassa University of Sri Lanka, Sri Lanka

Chapter 80
A Review of Antecedents of Online Repurchase Behavior in Indian E-Commerce Paradigm Shift 1578
Syed Habeeb, National Institute of Technology Warangal, India
K. Francis Sudhakar, National Institute of Technology Warangal, India

Chapter 81
Effect of Online Second-Hand Shopping Experience on Repurchase Intention: Evidence From Indian Shoppers 1598
Murali Swapana, VIT Business School, Vellore Institute of Technology (VIT), Vellore, India
Chandrasekaran Padmavathy, VIT Business School, Vellore Institute of Technology (VIT), Vellore, India

Chapter 82
Consumer E-Loyalty for E-Grocery Shopping in a Metro City of India: Role of Flow and TAM Antecedents 1612
Sablu Khan, Department of Business Administration, Aligarh Muslim University, Aligarh, India
Adil Khan, OP Jindal University, Raigarh, India

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Chapter 83
Adoption of E-Commerce Among Travel Agents in Brunei Darussalam 1633
Md Hisyamuddin Hamir, School of Business and Economics, Universiti Brunei Darussalam, Brunei
Nurul Qamarina Ali Sham, School of Business and Economics, Universiti Brunei Darussalam, Brunei
Siti Nazihah Ahmad, School of Business and Economics, Universiti Brunei Darussalam, Brunei
Nur Khalifah Ibrahim, School of Business and Economics, Universiti Brunei Darussalam, Brunei
Shazedah Osman, School of Business and Economics, Universiti Brunei Darussalam, Brunei

Preface

Technology, while completely changing the processes and efficiencies of business operations, has also changed the way in which businesses locate and engage with consumers. The introduction of e-commerce to companies has allowed for the rapid expansion of consumer bases, providing 24/7 service and shopping possibilities that previously were impractical in traditional commerce. Subsequently, businesses began adopting e-commerce models into their business plans. These models proved convenient to businesses not only because of their accessibility, but also because of the ability to analyze consumer online shopping preferences and mold their products to better fit the needs of their consumers. Still, even as this digitalization has helped businesses, they must also be wary of security issues that arise with the overwhelming data that they create.

Staying informed of the most up-to-date research trends and findings is of the utmost importance. That is why IGI Global is pleased to offer this three-volume reference collection of reprinted IGI Global book chapters and journal articles that have been handpicked by senior editorial staff. This collection will shed light on critical issues related to the trends, techniques, and uses of various applications by providing both broad and detailed perspectives on cutting-edge theories and developments. This collection is designed to act as a single reference source on conceptual, methodological, technical, and managerial issues, as well as to provide insight into emerging trends and future opportunities within the field.

The *Research Anthology on E-Commerce Adoption, Models, and Applications for Modern Business* is organized into six distinct sections that provide comprehensive coverage of important topics. The sections are:

1. Fundamental Concepts and Theories;
2. Development and Design Methodologies;
3. Tools and Technologies;
4. Utilization and Applications;
5. Organizational and Social Implications; and
6. Critical Issues and Challenges.

The following paragraphs provide a summary of what to expect from this invaluable reference tool.

Section 1, "Fundamental Concepts and Theories," serves as a foundation for this extensive reference tool by addressing crucial theories essential to understanding the concepts of e-commerce in multidisciplinary settings. Opening this reference book is the chapter "New Economy, E-Commerce Businesses, and E-Businesses: Types, Similarities, and Differences" by Prof. Duygu Toplu Yaşlıoğlu of Istanbul University, Turkey, which explains the concept of business model in the new economy and the transfor-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

mation of business models into e-business models. This first section ends with the chapter "Influences and Intention of Consumer's Online Shopping Decision: Jordan as a Case" by Profs. Radwan Moh'd Al-Dwairi and Murad Al Azzam of Department of Yarmouk University, Jordan, which sheds light on consumers' attitudes towards online shopping decisions and extends the technology acceptance model ease of use and perceived usefulness of the technology acceptance model (TAM) with four factors: trust, security, privacy, and risk.

Section 2, "Development and Design Methodologies," presents in-depth coverage of the design and development of business models and consumer engagement initiatives through e-commerce. This section starts with "E-Commerce Business Model" by Profs. Durga Patel, Sachin Goyal, and Ratish Agarwal of University Institute of Technology, India, which provides an overview of the e-commerce business model, the history of e-commerce, the scope of e-commerce, the difference between e-commerce and traditional commerce, issues related to e-commerce, electronic data interchange, value chain, supply chain, and the pros and cons and limitations of e-commerce. This section ends with the chapter "Designing Indulgent Interaction: Luxury Fashion, M-Commerce, and Übermensch" by Profs. Christopher J. Parker and Stephen A. Doyle of The University of Manchester, UK, which explores the history and meaning of luxury and branding in relation to the current state of m-commerce in fashion.

Section 3, "Tools and Technologies," explores the various tools and technologies used in e-commerce adoption and to ensure the efficiency of the process. This section begins with "Electronic Commerce and Decision Support Systems: Theories and Applications" by Prof. Kijpokin Kasemsap of Suan Sunandha Rajabhat University, Thailand, which argues that utilizing e-commerce and DSSs has the potential to enhance business performance and reach strategic goals in modern business. This section ends with the chapter "Understanding Vietnamese Consumer Intention to Use Online Retailer Websites: Application of the Extended Technology Acceptance Model" by Prof. A. F. M. Jalal Ahamed of the University of Skövde, Sweden; Prof. Yam Limbu of Montclair State University, USA; Prof. Long Pham of the University of Louisiana at Monroe, USA & Thuyloi University, Hanoi, Vietnam; and Prof. Ha Van Nguyen of Banking Academy, Hanoi, Vietnam. This chapter examines the applicability of an extended technology acceptance model (TAM) that incorporates trust, perceived risk, and self-enhancement as antecedents to the TAM constructs.

Section 4, "Utilization and Applications," describes how businesses can adopt and utilize e-commerce to enhance their operations and provide better customer service and engagement. The opening chapter in this section, "Reverse Logistics in E-Retailing," by Prof. Senem Ergan of Namık Kemal University, Turkey and Prof. Ayşe Akyol of Trakya University, Turkey, indicates the importance of reverse logistics in e-retailing. This section ends with the chapter "Exploring Online Marketing Adoption Factors Among Used Car Sellers in Ghana" by Profs. Masud Ibrahim and Anthony' Freeman Mensah of University of Education, Winneba, Ghana and Prof. Frederick Asare of Kumasi Technical University, Kumasi, Ghana, which explore factors responsible for the adoption of online marketing by secondhand car dealers to sellers in Ghana.

Section 5, "Organizational and Social Implications," includes chapters discussing the impact of e-commerce on society and shows the ways in which e-commerce is used in different industries and how this impacts business. The chapter "Examination of the Extent and Effects of Strategic Management on E-Commerce Companies" by Prof. Zafer Adiguzel of Istanbul Medipol University, Turkey opens this section by examining and analyzing the companies that have commercial activities in e-commerce environments in terms of strategic management. This section ends with the chapter "Adoption of E-Commerce Among Travel Agents in Brunei Darussalam" by Profs. Md Hisyamuddin Hamir, Nurul Qamarina Ali

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sham, Siti Nazihah Ahmad, Nur Khalifah Ibrahim, Shazedah Osman, and Amalina Zuadi of School of Business and Economics, Universiti Brunei Darussalam, Brunei, which explains the important role that information and communication technology has played in the tourism industry.

Section 6, "Critical Issues and Challenges," presents coverage of academic and research perspectives on challenges to e-commerce in different methods, technologies, and techniques in varied industry applications. Opening this final section is "The Implications of Unethical and Illegal Behavior in the World of E-Commerce" by Prof. Adel Ismail Al-Alawi of University of Bahrain, Bahrain; Profs. Arpita Anshu Mehrotra and Hala Elias of Royal University for Women, Bahrain; Prof. Sara Abdulrahman Al-Bassam of The Social Development Office of His Highness the Prime Minister's Diwan, Kuwait; and Prof. Hina S. M. Safdar of University of Bahrain, Bahrain, which identifies the behaviors of the consumers and sellers of e-commerce in Bahrain. The final chapter in this section is "The Challenges and Opportunities of E-Commerce Data Collection in Indonesia Compared to BRICS Countries" by Muhammad Basorudin, Khalilur Rahman, Nadra Yudelsa Ratu, Easbi Ikhsan, and Wida Siddhikara Perwitasari of BPS-Statistics Indonesia, Indonesia, which explains the rapid development of e-commerce in Indonesia and its challenges.

Although the primary organization of the contents in this multi-volume work is based on its six sections, offering a progression of coverage of the important concepts, methodologies, technologies, applications, social issues, and emerging trends, the reader can also identify specific contents by utilizing the extensive indexing system listed at the end of each volume. As a comprehensive collection of research on the latest findings related to e-commerce the *Research Anthology on E-Commerce Adoption, Models, and Applications for Modern Business* provides managers, e-commerce managers, marketers, advertisers, brand managers, executives, IT consultants, practitioners, researchers, academicians, and students with a complete understanding of the applications and impacts of e-commerce. Given the vast number of issues concerning usage, failure, success, strategies, and applications of e-commerce in modern industries, the *Research Anthology on E-Commerce Adoption, Models, and Applications for Modern Business* encompasses the most pertinent research on the impacts, uses, and development of e-commerce.

Istanbul University, Turkey

ABSTRACT

Electronic commerce and electronic business concepts are highly researched in recent management literature. Network economy has revealed e-commerce, a new trade route that is carried out over the interlinked computers and mobile devices. E-commerce is a method used by almost all businesses that are physically processing. Therefore, there should be a significant distinction between e-business and e-commerce. With the development of e-commerce, new ways of doing business have emerged. Thus, many e-commerce companies have emerged, traditional businesses have started trading in electronic networks, and new business models have begun to be created in digital environments. In order to understand how e-businesses make money, many business models have been studied. For this reason, the concept of business model in the new economy and the transformation of business models into e-business models are examined. In line with this, it is aimed in this chapter to examine e-businesses, to clarify e-business models, and to explain e-commerce types and e-business model types in detail, with examples.

INTRODUCTION

E-business models, which have many similarities with classical business models, continue to develop and diversify along with e-commerce. In the new economy, many studies are being conducted to examine new business models in order to understand how e-commerce enterprises survived or why they could not survive (Persson & Stirna, 2001). Many researches indicate there has been an organizational transformation in some sectors and enterprises with the development of information and communication technologies.

E-commerce is defined as "doing things electronically", in general. European Union Commission defines e-commerce as "selling goods and services over the Internet" and OECD defines it as "trading

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of products or services through computer networks". E-commerce includes the electronic trading of physical goods and nonphysical products such as information and data, and this trading includes steps such as online marketing, orders, payment, and post-delivery services (Timmers, 1998). This concept is also referred as "Internet-based business", "e-trading" and "e-market". Even though the product and services are ordered electronically, payment and delivery processes are not necessarily online. In other words, while e-commerce businesses perform their operations in the traditional sense, they can fulfill the transactions through the Internet (Zott et al., 2011).

Identifying e-commerce as a world-wide trading on the network will be a depreciatory assumption. Although e-commerce is perceived as a buying-selling process only because of its trading concept, it is understood that it has a much wider meaning with the use of e-business term (Özmen, 2013). E-business term was first used by IBM in 1997. According to IBM's definition, e-business is defined as "transforming the main business processes using Internet technologies" (https://www-03.ibm.com/ibm/history/ibm100/us/en/icons/ebusiness/transform/ accessed at 11.01.2019).

It is understood that e-business is a term that includes not only buying-selling but also other processes, from accounting to human resources, production to marketing, from the acceptance of the order to automation and the use of information technologies. In short, e-business includes new ways of doing business, new business methods. It is the restructuring of all processes from e-business supply chain to customer relations (Dubosson-Torbay et al., 2002).

New business models have started to surface with the emergence of e-commerce and have become powerful components in e-commerce environment (Kalakota & Robinson, 2001). However, e-commerce is a method used by almost all businesses that are now physically processing. Therefore, there should be a significant distinction between e-business and e-commerce. Every e-commerce business cannot be referred as e-business, but every e-business has to include electronic commerce.

In order to understand how e-businesses make money, many business models that emerged in the new economy have been studied in various ways. In fact, although e-businesses are in a different perspective from each other, they actually have the same purpose and working on the same subject. The most critical issue in the e-business models is whether these companies can be compared and whether they can be examined under the categories. Common point in the planning of e-business models is to clarify the revenue models and to develop the business processes and strategies to the finest detail. (Dubosson-Torbay et al., 2002). Some researchers have made classifications of e-business according to the degree of functionality and innovation (Timmers, 1998), some according to the ability of economic control (Tapscott et al., 1999), the type and degree of relationships and the power of buyers and sellers (Pigneur, 1996).

E-commerce and e-business concepts are highly debated and researched in the recent management literature. With the development of information technologies, businesses in the digital age have had to adapt themselves and their business models to this era. Thus, many e-commerce companies have emerged, traditional businesses have started to trading in electronic networks and new business models have begun to be created in digital environments. In line with these developments, it is aimed in this chapter to examine e-businesses, to clarify e-business models, to explain e-commerce types and e-business model types in detail with examples.

BACKGROUND

New Economy and New Businesses

Changes triggered by computers, Internet and communication technologies have led to the formation of an economy called network economy. The network economy has also revealed the electronic commerce, a new trade route that is carried out over the interlinked computers and mobile devices. In the digitalization process, formed by the network economy, problems related to customers and business life have also been differentiated. Old ways of doing business have been insufficient from time to time to solve these problems. Thus, parameters of business management have changed, especially in terms of risks and gains. Organizational structures of businesses have changed and organizational structures based on information and information technologies have emerged instead of the old hierarchical organization structures.

The very first rule of business in the new economy is being agile and creative. Frame of time is expanded and can be offered every hour of the day, every day of the year through the Internet. Importance of distance has reduced. Value is created with abstract services and information creation rather than tangible products (Meyer & Davis, 2000). Businesses in the new economy, must be agile. They have to offer their products and services faster than before. Hence, process of production should be finalized rapidly in order to proceed offerings. That is, business now needs to supply, produce and market faster. In order to carry out these transactions fast, they have to utilize their management skills better at every stage and have to perform business functions faster.

In global competition, being agile is an important advantage. Thanks to the Internet, users have the opportunity to reach the information they want from any location and at any time. Internet, along with wired and wireless connections, led to an abundance of data and information. Increasing number of subscriptions to social networks through Internet, interactions and sharing add value to the business as long as it is managed correctly. As the number of Internet users, the number of transaction and shoppers on networks, number of buyers and sellers (who are members of virtual market places) increase, the potential value created through these networks also starts to raise (Amit & Zott, 2001; Wirtz et al., 2010). As an e-retail company begin operating on the Internet, the more visitors to its website are attracted, and therefore more value is created in the virtual environment. Because of the traces left by those visitors, it is possible to gather feedback on product preferences, product or service advices, and negative opinions. These can be clearly identified in all types of business models operating on the Internet (Dubelaar et al., 2005).

Another important factor that changes the business rules of the new economy is the increase in the number of production factors. Creativity and innovation are added to the factors of production, which formerly were only enlisted as capital, labor, land and entrepreneur (Kim & Mauborgne, 1999). Accordingly, Internet-based new business models have emerged. Companies that were born in the Internet and which did not exist in the tradition trade life, were called "virtual" formerly. During this period, not only dot-com companies but also the companies which are trading in the traditional sense have increased their productivity and earnings by being included in network-based practices. Using information and network technologies, companies bring innovation not only in the products and services, but also in their business models, processes and management approaches. So, businesses that can develop their skills and abilities in new ways of doing business have come forward (Morris et al., 2005; Onetti et al., 2012).

Digitalization of information and communication infrastructures is economy based. Developments in the digital economy have significant impact on the creation of economic systems and economic value.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Basic features of digital economy are structures, processes, products and infrastructure (Zimmermann, 2000). Not to be the best in the market or to produce products in the most efficient way important in the digital economy; it is important to win the customer, to satisfy their needs, to have the best strategy and business model (van Eijsden, 2000). Powerful new digital technologies have created a serious change in customer behaviors. When a product, interaction, or device starts to digitize, there is no power to stand in the face of this, and in this case the old business models cannot be flexible, adaptable or unable to adapt so the old business model has to be deleted (Rogers, 2016).

BUSINESS MODEL CONCEPT

The concept of the business model, which includes all the processes of a business, covering its activities and describing the business plan, is closely related with the economy. Nowadays, when the digital transformation is experienced, the business structures that are transformed with the development and expansion of the Internet are also affected by this. The geographical distance is no longer a problem with the new economy, also markets expanded globally. Sales, production and marketing activities have become independent of the place. The globalization of the markets has led to the globalization of competitors. Thus, the definition of competition and the expectations of customers have changed as well.

Drucker's 1994 work in Harvard Business Review did not explicitly mention the business model, but there are a number of assumptions about what a business should and should not do. Moreover, some of the assumptions suggested by Porter, in an article published in Harvard Business Review in 1996, were also accepted as a starting point of the business model concept by some researchers (Ovans, 2015). While defining the business model, it is necessary to take Drucker's assumptions into account and to answer the questions by Porter such as "who is the customer?", "what creates the customer value?", "how can we earn money in this business?", "how can we provide value to customers?". The reason to answering those questions is the definition is that the business model is a set of elements of explaining how businesses operate (Magretta, 2002).

According to some researchers, the business model is defined as the concept that explains the business logic (Timmers, 1998; Teksten, 2001; Petrovic et al., 2001), while others refer to it as the link between business strategy, business processes and information systems (Nilsson, 1999; Osterwalder & Pigneur, 2002). Difference between these two interpretations of the business model roots from the relation of the business model with the concepts of strategy, business processes and technology. In the first interpretation, these three concepts are included in the definition of business model, while the second interpretation accepts them as interconnected components, which are set at different levels of pyramid structure. In this case, a business model is considered as the conceptual and architectural implementation of the business strategy and represents the basis of the implementation of business processes and information systems (Pateli, 2003). Many businesses are designing and evaluating their business models independently from the environment. However, especially without an examination of the business models of competitors, this can lead to failure (Casadesus-Masanell & Ricart, 2011).

Timmers, who mentioned the concept of business model for the first time, describes it in three different ways in his article published in 1998;

- Design of product, service and information flow where many different elements and their roles are combined.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Identification of potential profits created or will be created by different business elements.
- Definition of income sources.

There are many different studies that define the concept of business model in various ways. Some of them define it as the technical capacity as an experiment-based logic that brings together the realization of economic value (Chesbrough & Rosenbloom, 2002), some as the basic logic of creating and retaining value within the network of values (Shafer et al., 2005).

According to Dubosson-Tobay et al. (2002) business model frame is divided into four basic elements. First of all, the product or service offered by the business should create value for the target customer, secondly, the relationship capital created by the business is used to satisfy the customer and generate sustainable income. Thirdly, designing of a structure to create value and creation of a network of stakeholder relations; and finally, the expected financial effects such as cost and revenue as a result of the previous three.

More specifically, Osterwalder et al. (2005) described the business model as a concept consisting of series of elements. These elements are value propositions (product, service offerings, customer segment identification and customer relations), activities, resources, shareholders, distribution channels, cost structure and revenue model. In 2010, Zott and Amit's approach to the business model was activity-based perspective and refers to the selection of some activities, system's activity structure and answering for questions concerning the realization of those activities. Referring to these perspectives, it is argued that the supply chain should be taken into consideration while developing a business model. In this respect, the business model consists of two main elements. First, everything related to production/service activity (design, raw material procurement, manufacturing, planning etc.), secondly everything related to the sales and marketing (finding and accessing customers, realizing the sale, distributing the product, or performing the service, etc.) (Ovans, 2015).

Three features of a good business model are listed below (Casadesus-Masanell & Ricart, 2011).

- It should be consistent with goals of the business. Choices made while designing business models should be aimed at achieving the goals.
- It should be self-strengthening. The choices made when designing business models must complement each other and must have internal consistency.
- It should be stable and durable. A good business model should be able to maintain its effectiveness and integrity against various threats.

For the success of the business model, implementation is as important as formulation. It should be checked whether there is a difference between the activities carried out during the implementation and the results and the plans. In case in a change of circumstances and conditions, corrections should be made in the business plan if necessary. Initially planning of a business model may be more successful or less successful than expected. In both cases, the plan is unlikely to have been made properly. If the result is unsuccessful, it may be considered that the planned business model is not working properly. Therefore, if it is more successful than expected, it can also be assumed that the positive developments could not have been predicted well enough (Özmen, 2013).

It has always been important for businesses to achieve competitive advantage and make it sustainable. However, since digital copying and replication is quite easy nowadays, businesses need to be innovative not only in products and services but also in processes and business models to be successful. In the past,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

competition has taken place between competing companies that are similar to each other, with fixed boundaries and clearly defined sectors, and now competition can still be experienced among unrelated businesses. Previously, businesses used to create value through their suppliers, sales channels. But now, because of digital revolution, boundaries between sectors have become transparent, distinction between stakeholders and competitors is changing, and the value creation can be made through different channels (Rogers, 2016).

E-COMMERCE AND E-BUSINESS MODELS

E-commerce, in the most general sense, is defined as "doing business electronically". European Union Commission has defined e-commerce as "the goods and services being sold on the Internet", OECD has defined it as "trading of products or services through computer networks" and World Trade Organization definition is "the production, advertisement, sales and distribution of goods and services over the Internet". E-commerce involves the electronic trading of physical goods and intangible products such as information and data. And this includes the steps of online marketing, ordering, payment and post-delivery services. It also facilitates the provision of e-commerce services and electronic transactions such as after-sales support and online assistance (Timmers, 1998). Even though the product or services are ordered electronically, payment and delivery processes do not have to be online. In other words, e-commerce companies perform their operations in the traditional sense, while they can do their job through the Internet (Zott et al., 2011).

New ways of doing business with the Internet are constantly improving. Most of these business practices attract the attention of consumers/customers and customer focus is prioritized. For those who are not directly in relation with the consumers, e-commerce can also be used to carry out business to business (B2B) transactions. New models in e-commerce are run in all types of business forms, sucha as business to business, business to consumer and business to government (Timmers, 1998). In a study which examined the strategies of e-commerce companies conducted by Mohapatra (2013), e-commerce companies are classified as business to consumer (B2C), business to business (B2B), consumer to consumer (C2C), consumer to business (C2B), business to employee (B2E), government to government (G2G), government to business (G2B), business to government (B2G), government to consumer (G2C) and consumer to government (C2G). From this point on, it is important to determine the direction of e-commerce.

E-commerce, which has been growing very rapidly especially in the last 10 years, has reshaped the shopping habits of consumers and therefore the business models of enterprises. Benefits of e-commerce, which continues to grow rapidly for both society and economy, are listed below (TÜSİAD, 2017);

- Restrains the hidden economy, increases productivity and supports the growth of enterprises.
- Contributes to the development of industries such as logistics and information technologies.
- Eliminates the costs of physical transactions and enables SMEs to compete with large enterprises.
- Increases the export potential by ensuring that products and services are promoted globally more easily, faster and at lower costs.

Defining e-commerce as a world-wide trade ground on the network is the main assumption. Although e-commerce is perceived as a trading process only because of its trading concept, it is understood that

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

it has a much broader meaning with the use of e-business term (Özmen, 2013). E-commerce, which is perceived as the use of Internet in business functions such as communication, marketing and sales channels, continues evolve even though it moderately changed the business models. However, besides the evolution of e-commerce, it should be said that it is in fact a revolutionary development (Zimmermann, 2000; Kalakota & Robinson, 2001). This development will radically change the processes and structures within and between industries, and will help the digital economy pave the way for businesses. This situation is clearly predicted to have a major impact on basic business models. Most importantly, digital technologies are increasing the power of business models that enable an enterprise to create value by improving its interaction with other businesses or customers (Rogers, 2016).

E-business term was first used by IBM in 1997. According to IBM's definition, e-business is defined as "transforming the main business processes using technologies". Thus, it is understood that e-business is a term that includes not only trading but also other processes, from accounting to human resources, production to marketing, acceptance of order to automation to delivery and using information technologies. In short, e-business includes new ways of doing business, business model and business methods. E-business is an enterprise that covers the restructuring of all processes from supply chain to customer relations.

A business model is to build the business and its partners in order to create value and create a profitable and sustainable revenue stream. E-business models have the purpose of creating value by providing information to related parties, providing communication, buying and selling of activities, providing an exchange of ideas. It has been suggested that e-business model should consist of the following elements (Dubosson-Torbay et al., 2002):

- Product innovation (value creation, definition of target market, capabilities)
- Customer relations (customer feedback, customer service, brand building)
- Design management (resources/assets, activities/processes, shareholder relations)
- Financial aspects (revenue, cost, profit)

As mentioned above, new business models have started to emerge with the emergence of e-commerce and have become powerful components in e-commerce environment (Kalakota & Robinson, 2001). There should be a significant difference between e-business and e-commerce. Every e-commerce company cannot be defined as an e-business, but every e-business has to make e-commerce.

E-business models have the same objectives as the traditional models. Business models help businesses to identify their vision and strategies, redesign and regulate their business operations, facilitate the sharing of information about their processes and visions, and to ensuring that the decisions made are shared with shareholders (Persson & Stirna, 2001). In e-business models, there are targets such as increasing efficiency, the number of customers and the number of transactions. Traditional enterprises involved in the digital transformation, experience significant challenges in terms of ensuring integration of their business processes using information technologies. In order to accomplish digitalization of all processes, various databases, different software and hardware must be integrated. A business within the digital transformation process should not only build and manage a website, but should also be able to transform all its processes into e-business (Özmen, 2013).

E-business models create value by combining two or more sides within the framework of the work done instead of creating the value alone. For example, while e-marketplaces such as eBay and AliExpress bring together all kinds of buyers and sellers, Uber serves through a system that brings together people

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

who need a vehicle and drivers who use their own vehicles (Rogers, 2016). In addition to the previously mentioned Timmers' business model definition, Klose and Lechner defines business model as design of products and services that meet customer needs, determination of the many different actors, their roles, relationship between them and benefits of different actors and sources of income. It is important to analyze and understand current developments to answer the questions within this definition and to design effective business models for the future. Analyzing them reveals four key elements that characterize the evolving digital economy. This analysis process, which includes observations, researches and experiences related to the real world, makes it necessary to concentrate on issues including the structure, business processes, products or services and infrastructure of enterprises (Klose & Lechner, 1999; Zimmermann, 2000).

E-Transformation Process and Being E-Business

E-businesses add value to all parties (customers, manufacturers, suppliers, employees, and managers) provide convenience, comfort, benefit and cost savings. It is essential that enterprises adapt to new technologies and new management approaches in order to sustain in the competitive environment. In recent years, it has become more important to start e-transformation process with the correct goals and strategies and to take a quick lead.

The most important success factors for the transformation of business processes into e-business, are the re-definition of enterprises into being a successful e-business, being visionary and making strategic decisions. It is not the old paradigms that are important in the process of transforming traditional businesses and their ways of doing business, but the realities of new economy and the realities of e-commerce. One of the main reasons for the negativity of e-transformation efforts, is the lack of business and management skills (Lee, 2001; Osterwalder et al., 2005).

Process of transforming businesses into e-businesses, managers to e-managers, requires strategic direction. This process starts with the enterprise deciding how to position itself in the market. In other words, it must first decide how it wants to see itself in the future. A business can carry through the stages of e-transformation process by spreading them to a certain time period, or it may initially emerge as an e-business, designing all business processes as e-processes (Hanna, 2009; Özmen, 2013).

Efforts of companies to differentiate themselves from their competitors have gained a different momentum in recent years due to the opportunities offered by Internet technologies. One of them is to set up the website. Companies want to reach more customers by establishing a website and communicate better and continuously with their existing customers. The first thing an e-business has to do is to build a website that users will like and enjoy during their visit. If the website visitors cannot access the information they want in the first few seconds, they may get lost on the site. Or if the pages are visually choking, visitors may prefer another website (Reichheld & Schefter, 2000). Taking care of such issues is the first rule of being an e-business.

Purpose of e-business models is to inform the relevant parties, to create value, to communicate, to buy/sell, to exchange ideas and to share (Zott et al., 2010). Also, a revenue model is extremely important.

In recent years, people have been exchanging ideas with each other, sharing their comments and complaints in social networking sites and blogs. Those shares reach very large audiences on aforementioned channels (Harris & Rae, 2009). For this reason, companies should visit at least certain portals frequently and should examine the negative comments about the products and services.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Basic elements that must be integrated for strategic activities in e-business ecosystem are; customers, markets, products, processes, organizations (structure and relations), shareholders, financing, social values and government policies. E-business ecosystem, that emerged from this point of view, is a network of customers, suppliers, distributors and trading service providers. E-businesses use the Internet for business-related basic communications and operations, including creation of value for new customers, transforming competition rules, moving people and resources to unprecedented performance levels (Pateli, 2003).

Zimmermann (2000) defines four elements that are changing for e-business models, and in the light of these elements given below, points to be taken into consideration while creating new business models are listed as;

- In today's e-commerce models, there is a value chain in which the customers and suppliers interact directly. E-commerce has changed the industry structures and differentiated the value creation process. Businesses can be divided into units or transformed into a modular structure. Technological ventures, especially called "start-ups", are often a single product enterprise that focus on one or more services or products (Sarkar et al., 1995). Rather than focusing on the entire value chain, businesses have started to pay attention on customer relations by focusing on their core competences.
- Process of creating value reversed, focusing on the customers' wishes and needs has come to the fore. In a structure focused on delivering personalized products or services, business processes have made the customer an element of market value that should be deemed as an individual. Industrial mechanisms have constituted the necessity for the processes coordination not only within the business, but also between enterprises.
- Especially in information intensive products, content is usually prepared with multiple contexts and infrastructures. Thanks to the infrastructure of information and communication technologies, each unit of a product is prepared in a flexible and diverse context. For example, latest breaking news are available through a large number of websites. Thus, information needs to be updated continuously. There are also many ads and other content on these websites.
- Many innovations in value creation processes and many technical platform infrastructures are needed to produce new products. These technical platforms are required for the actualization of the business models. Especially from business to business (B2B) perspective, businesses from different industries should meet the needs of different actors.

In addition to the above-mentioned elements, it is necessary to perform some basic functions for the success of the e-businesses. One of these is the planning of business processes. It is determined by whom these processes will be managed and which tasks will be maintained. It is necessary to revise the business functions within the framework of the business model. It should be noted that the purpose it to generate revenue while preparing a business plan. It is important to calculate the costs well and identify the return of the investment for this revenue to turn into profits (Özmen, 2013). It should be kept in mind that it is difficult to create a sustainable business model and provide a competitive advantage in the digital age where product life cycles are very short.

E-businesses often come to the forefront with the value created by the customer and achieve success. These business models often have a lot in common with the value they offer. E-businesses generally make it possible to offer the same product or service at a cheaper price. In addition, many new e-business

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

models offer a system where some service is provided free of charge. The most common value source for e-business models is that the content or services can be accessed remotely from anywhere. Most e-businesses make purchasing easy and simple by eliminating any problem in the sales process. E-businesses give importance to personalization, allowing people to choose and use the service or product that suits their needs (Rogers, 2016).

E-Business Types and Examples

In order to understand how e-businesses earn money or not, various business models have been studied. Common point in the planning of e-business models is to clarify the income model and to develop business processes and strategies to the finest detail. The most critical issue in e-business models is whether it can be used to compare the companies that implement these models and whether they can be examined in categories (Dubosson-Torbay, 2002).

When e-business models are examined in general terms, can be listed as: virtual market places that bring buyers and sellers together and offering auction opportunities, private shopping opportunity sites that offer products or services at discounted prices, search engines, portals, supply chain enterprises that bring together suppliers and manufacturers, social networks that provide social interaction and information sharing, blogs, service providers that provide e-commerce solutions, distribution networks performing electronic and physical distribution (Özmen, 2013). According to the e-business model classifications in the literature, some of them have been classified according to the degree of functionality and innovation (Timmers, 1998), some according to the ability of economic control (Tapscott et al., 1999), some according to the type and degree of relations and some according to the power of buyers and sellers (Pigneur, 1996).

According to Tapscott et al. (2000)'s study, e-business models should be evaluated by the main theme, the value offered to the customer, the customer's role and knowledge and finally by main business processes. Main theme and main business process criteria refer to the mission, purpose and tasks of the enterprise to achieve its goal. Main business processes will be shaped around the main objectives of an enterprise. Value proposition criteria should answer the question of how the business model offers benefits to its users. For example, Amazon offers buyers the opportunity to get the product they want, while seller provide income for Amazon. Thus, it creates value for both sides. Another factor in the evaluation of e-business models is the role of the customer. Customers often play an important role in business processes. Customers who evaluate the product they buy in shopping sites, make comments on the books they buy in book sales sites, evaluate their vacation and the hotel they stayed on tour and travel sites. These factors affect business processes and sales directly. Usability of knowledge acquired by the business while implementing e-business models is related to how the business analyzes the information obtained and how it benefits from the findings of the analysis (TÜSİAD, 2017; Özmen, 2013). For example, in online book sales sites such as Barnes & Noble, all of the products that the user looks at, buys or discontinues to look for are recorded with a profile of his or her personal characteristics, such as his or her age, gender. These are all the information they need to focus on and analyze. When this information is analyzed correctly, customer satisfaction and loyalty can be improved.

Researchers working to examine the business model have developed many different schematic presentations about the applicability of models. In a study conducted by Weill and Vitale in 2001, tools necessary for the design and analysis of the e-business models included in these presentations were examined and analyzed in a simple manner. The "business model schematic" as a result is divided into

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

three. The first is roles and relationships (electronic and primary, its customers, suppliers and collaborators), the second is major flows of product, information and money, and the third is revenue and other benefits each participant receives (Fielt, 2014). In that study, various e-business models were examined in accordance with these components.

Many different researchers have classified e-business models in various ways (Tapscott, 2000; Timmers, 1998; Applegate, 2001; Rappa, 2003). All types of e-business models are described by examining three of the most accepted classifications. First of these classifications was made by Timmers (1998) and the other was by Tapscott et al. (1999), and third, by Zott et al. (2011). E-business models discussed according to these classifications are briefly explained below.

One type of e-business model is so-called *e-shops,* which refers to Internet marketing and promotion of a business or a store. The priority of e-shop is the promotion of the company's products and services through the Internet. It is often used in conjunction with traditional marketing channels. Customers have the opportunity to compare product offerings, evaluate more options, get better information and make transactions such as selection, purchasing and acquisition easier (Timmers, 1998; Zott et al., 2011). An example of this business model is the online ticket sales of airlines, online stores of brands such as Zara, Gap or Walgreens.

Another e-business model is the where e-shops of well-known brands are often found. This business model, *e-mall*, provides a common technological platform for different e-shops. Thus, e-shops, which are members of e-malls, have some benefits such as lowering some of their costs and not having to deal with services like electronic payment and promotion. Besides, for customers, it is possible to examine and compare many brands at once (Timmers, 1998). It brings customers who want to shop over the Internet together with sellers who do not have the opportunity to host or cannot sell through a web site. Zimmermann (1997) acknowledges that an e-mall is a regional marketplace with multi-national products within the same region. An e-mall may also contain products from multiple contiguous regions (Laudon & Traver, 2016). Globally, e-malls are the most important purchase sites and their revenue model involves advertising, subscription, sales, affiliates, and transaction fees (Bahaddad et al., 2012). There are many examples of this business model. An e-mall hosts many online merchants. Examples of this model are Yahoo!Shopping, zShops and so on (Wen et al., 2001).

Another e-business model, *e-procurement*, depends on the products and services by offering them electronically. Large enterprises or government authorities can operate the e-procurement process over the Internet. Products or services offered to the large supplier network offer advantages such as lower cost, better quality products/services, better delivery and lowering of procurement costs (Timmers, 1998; Zott et al., 2011).

Similar to auction or traditional bidding, electronic version is called *e-auction*, which is an auction and bidding environment over the Internet (Zott et al., 2011). Such models are usually implemented with multi-media presentations of products and are carried through the integration of stages such as bidding, making deals, payment and delivery. Revenues of the e-auctioneers' businesses consist of the use of technology environment, payments made through the transaction and advertising revenues. For buyers and suppliers, there are benefits such as being more efficient, time-saving and global trading (Timmers, 1998). This business model is used by many different industries. There are e-auction websites established for different areas ranging from antiques and artworks to housing sales.

Virtual communities are based on the acquisition of the final value from members (customers or suppliers). Members enter the basic knowledge of the virtual community and obtain the necessary environmental elements from them. The virtual community offers the necessary marketing operations

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

to create customer loyalty and receive customer feedback. In such models, revenue is generated from membership fees and advertisements (Zott et al., 2011).

Companies that want to meet their products with more customers and to test their operational processes and competencies use *e-marketplaces.* These businesses, in agreement with the e-marketplace, benefit from their systematic infrastructure, network, knowledge and traffic (Brunn et al., 2002). The e-marketplace concept provides the opportunity for companies to coordinate complex and multifunctional activities of supply chain processes through web-based applications (Eng, 2004). Ebay is one of the most important enterprises of the group of e-marketplaces in the world. Ebay, Amazon and Alibaba, the pioneers of e-marketplaces in different formats, have been very successful and have achieved a significant market share in the retail sector with thousands of suppliers and millions of customers.

Another e-business model is the third-party marketplace where an enterprise leaves the web marketing of the business to a third party (usually in addition to other channels). Generally, it serves as an interface where product catalogs are provided to suppliers, it ensures the secure execution of the processes such as branding, payment, logistics and ordering (Timmers, 1998; Zott et al., 2011). For example; "Google My Business" application operates as a digital media that manages business information that the business does not have.

Enterprises that specialize in one step of the value chain such as electronic payment or logistics, called *value chain service providers* (Timmers, 1998; Van de Vorst et al., 2002). Freight operators such as FedEx or UPS, payment businesses such as PayPal are examples of this model. Especially, e-businesses that specialize in terms of delivery, have created many different models.

Another business model focuses on many steps of the value chain, which creates value through the flow of information between these steps. Revenues of *value chain integrators* are usually obtained from consulting and processing fees (Timmers, 1998; Cagliano et al., 2003). Business called "Global Value Web" can be used as an example. The business defines itself as a company that serves to connect global businesses and creates a global value chain (https://global-value-web.com/index.html). It is a company that integrates the value chain steps among many companies in various industries, provides quality solutions and engineering services.

Business model of the enterprises that provide the necessary tools and information environment to ensure cooperation between enterprises also called *collaboration platforms.* Businesses in this model are focused on specific functions such as design and engineering, or do project-based work through virtual teams (Timmers, 1998). There are many companies that have a business model in the form of a collaboration platform. Looking at the examples of this model, it is seen that there are many different companies that provide environment and human resource for project based works.

Yet another e-business model is a large number of new information provisioning services, which are created by large amounts of data on open networks. These type of enterprises are called *information brokers.* In brief, they have emerged to provide services such as information search, customer profiling, investment advice and commercial business information services (Timmers, 1998; Hayes & Finnegan, 2005). Acxiom, for example, collects customer information to provide some businesses with information for marketing activities.

Another e-business model is *trust or other third party services*. They usually provide trust services, that are provided by certification authorities and electronic notaries. These services may charge subscription fees or service fees, combined with software sales and consultancy revenues (Timmers, 1998; Rappa, 2003).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Types of e-business models discussed in this part, have been obtained by considering many different sources. Such a viewpoint, which makes it easy to classify e-business types, of course, can be transformed and changed by the development of digital technologies. Increase in digitalization leads to different factors in the transformation from e-business models to digital business models. For this reason, new business models will lead to different classifications or different types of e-business models.

Internet entrepreneurs who set up an e-business model, or businesses planning to survive in the digital economy, were generally inspired by business models that first emerged in the United States. For example, entrepreneurs inspired by eBay's business model have implemented similar business models in many countries and have been successful.

Amazon, founded in 1994, has become a stand-alone brand thanks to its e-business model. As an enterprise that started to work primarily by selling books, it has achieved great success by selling twenty thousand books in the first two weeks of its establishment. Today, Amazon is an e-business with more than 350 centers across the globe (Eczacıbaşı, 2018), selling almost all of the products. Along with this, cloud technology systems called Amazon Cloud, have become an important opportunity for technology entrepreneurs today. Amazon's business model is based on an innovation that provides interface connectivity to more than two million stores that it doesn't own or manage (Keen & Wiliams, 2013).

Another important example of e-business model was the establishment of Uber company, which led to the birth of a new sector as a result of dream of an entrepreneur named Garrett Camp. E-business models similar to Uber company redefine the concept of transportation, through sharing economy, as competing with taxis all over the world. In US, Lyft, BlaBlaCar in France and Addison Lee in London are companies using the similar e-business models (Rogers, 2016).

Another example is the business model of Airbnb, which was founded in 2008. Airbnb is growing rapidly and has more rooms than the most important hotel chains in the world (such as Hilton, Inter Continental). According to 2015 statistics, Airbnb provided accommodation for over 25 million tourists in more than 190 countries. Airbnb's business model is a platform that brings together the homeowners who want to rent part or all of their houses and customers looking for accommodation. The most important feature of Airbnb in terms of business model is that the value offered to customers is different from other enterprises (Kavadias et al., 2016).

It would not have been possible for Amazon to change the concept of shopping 20 years ago. Also, the idea that the world's largest hospitality company would not have a single hotel could not be understood five years ago. A similar example is that Apple has become the world's largest digital music company in almost 10 years, thanks to its business model, not products such as iPod and iPhone. Apple has created 92% of the market by supporting the iTunes app with smartphones. What is important here is that the new and different business model is transformed into one of the world's largest shops, selling not only music but all kinds of products and services (Eczacıbaşı, 2013).

Another e-business model application, known as TaskRabbit, was established in 2008 as an individual outsourcing site. Operation of the business model starts by logging into the system by describing what kind of service is needed and by continuing to communicate with them by selecting the most appropriate person to perform the requested service. Person who receives the service is responsible for payment via the application or website when the job is completed (Ay et al., 2018).

E-business models, sometimes creating a new sector from scratch, sometimes appearing as a different formation of the existing sector, can disable other players in the sector. For example, business model of Craigslist, a classified ads service, has had a very negative effect on the newspapers that obtained most of its revenue from classified ads. The most profitable section of the newspapers with high production

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

costs, is the classified ads sections that readers want to sell or rent for their various needs. However, a new e-business model created by Craig Newmark, a software programmer in the USA, with the idea that everyone is free to submit their ads online. With this idea, in a short period of time, it has become a global company which has been broadcasting in 70 countries and 13 languages and its contents have been read 50 billion times as day (https://www.feedough.com/how-does-craigslist-make-money/ accessed at 06.11.2018; Rogers, D. (2016). The Digital Transformation Playbook. Columbia University Press.)

Companies in several countries, such as GrubHub in US, Seamless in UK and Delivery Hero in Germany are another example of an e-business model. People can order online by ordering the most suitable meal by scanning the restaurants around their house or workplace. Value created by this model is that, it offers a more convenient experience than examining different restaurants websites, brochures and trying to order by phone (https://mediacat.com/caginin-otesinde/ accessed at 6.11.2018).

Examples given above are those that have created a unique business model and even give insight to those who come after. Different e-business model types and examples examined in this section. These e-business models continue to be added every day with the development and utilization of technology.

DISCUSSION AND CONCLUSION

Since the mid-1990s, commercial websites have become widespread. Success of e-commerce businesses, established since the 2000s, have attracted attention and the business models they implement are different from traditional business models. First enterprises operating in the early stages of e-commerce, are businesses that appear directly on the Internet. Many of them failed because of the proliferation of these enterprises and their activity only on the Internet. Later on, enterprises that are successful in traditional commerce and also integrate the Internet into their business model have been successful.

Effects of technology and Internet on our lives have increased with the beginning of the transformation of enterprises digitally. However, it is clear that digitalization is much more than just Internet usage. Business practices, workplace structures, relationships between employees, information sharing, customer relations and even competition are affected by digital transformation. In an e-business model, it is necessary to integrate the value network with technology, and most importantly, to use technology in every process of the business.

As it can be seen from detailed examples in the chapter, it is very common for businesses with traditional business models to convert their business model into e-business models. Companies invest in digital channels in order to create different experience from their competitors, and businesses in the service industry are trying to bring their business processes to a digital environment.

One of the most important effects of digital transformation is, its impact on business structures and therefore on business models. Nowadays, it is an inevitable necessity for businesses that sell to end customers to transform themselves in digital transformation. For this reason, it is thought that the differentiation of the business processes of all enterprises which are born in digital environment and trying to exist in digital environment, will bring a transformation to the business model literature and there are many opportunities to make research in this direction.

Chapter 2
The Affective Domain of E-Commerce

Vildan Ateş
Ankara Yıldırım Beyazıt University, Turkey

ABSTRACT

The purpose of this chapter is to examine customer perceptions in the affective domain that directly or indirectly influence the shopping process and purchasing decision between the online customer and online shopping sites. This chapter investigates the effects of nine different perceptions as perceived benefit, perceived control, perceived customer services, perceived customization, perceived risk, perceived security, perceived self-efficiency, perceived privacy, and perceived value on the trust, satisfaction, and loyalty of online customers. Revealing the effects of these relationships on online customer trust, satisfaction and loyalty is important for online shopping sites to maintain their existence in the long-run, be able to compete with others, and increase their profitability.

INTRODUCTION

Trade is an initiative that has existed among people since the ancient times. With the prevalent usage and centralization of the internet in our lives at the end of the twentieth century, it emerged as a new format that is known as "Electronic Commerce". In the digitalizing world, electronic commerce can also be defined as the digitalized state of commerce. Costs of accessing customers have decreased because the internet provides opportunities for the consumer to be able to access information about products or services. The price difference that was caused by reduced costs has led customers towards online shopping and increased the trade volume (Bourlakis, Papagiannidis, & Fox, 2008). Electronic commerce (e-commerce) was accepted by a wide proportion of the public and started to spread (Erbaşlar & Dokur, 2008; Xiong, Hou, Dong, & Nyberg, 2012). Sales made to consumers from e-commerce businesses worldwide have reached 3.3 trillions of dollars (Orendorff, 2017). This situation has brought along changes in shopping behaviors and habits for both vendors and customers in in a digitalized world.. This development revealed a different structure to those in markets where producers and consumers are found together, and e-commerce establishments started to interact with online customers all over the world.

The prevalence of e-commerce turned all people in the world into potential customers for vendors (Butler & Peppard, 1998; Civan & Bal, 2002). Now, consumers have become e-customers and been turned towards online shopping sites to meet most of their needs for goods and products. In this new form of shopping and trade, it was observed that the purchasing behaviors, shopping habits and general behaviors of consumers are influenced by various factors. This is why a need arose for reevaluation of the effects of some affective factors such as perception, motivation, learning, attitude and beliefs on this process. Additionally, the relationships between e-commerce businesses and online customers resulted in changes in and redefining of selling and purchasing behaviors. Customer satisfaction, trust and loyalty, which are among the main elements between the seller and buyer in trade, have become affected more by some affective characteristics of customers. The purchasing decisions of customers during the process of shopping from online shopping sites are affected more by affective factors (Akbar & James, 2014), and this influences customer satisfaction, trust and loyalty.

Considering the perspective of online shopping sites, having an organization in terms of e-commerce and increasing the satisfaction, trust and attachment of customers who prefer online shopping have become a key factor in terms of the purchasing behaviors of customers, profit margin and long-term growth goals. This is why it has become important to investigate the relationships between customer perceptions and customer satisfaction, trust and loyalty, as well as their effects on the purchasing decisions of customers (Srinivasan, Anderson, & Ponnavolu, 2002; Park & Kim, 2003; Flavia´n, Guinaliu, & Gurrea, 2006; Cyr, Hassanein; Head, & Ivanov, 2007; Kim, Ferrin, & Raghav, 2008).

In the following parts of this chapter, firstly the findings of studies which investigated customer perceptions, satisfaction, trust and loyalty and the relevant literature are presented. Secondly, online customer trust, satisfaction and loyalty are discussed in terms of e-commerce. The third part presents the customer perceptions that affect the trust, satisfaction and loyalty levels of online customers the most, and the relationships of the determined perceptions with customer satisfaction, trust and loyalty are separately presented.

BACKGROUND

The relationships between online customer perceptions and customer satisfaction, trust and loyalty and the effects of these on customers' purchasing decisions have been prevalently researched in recent years (Bilgihan, 2016; Ozkara, Ozmen, & Kim, 2017; Kim, & Peterson, 2017; Pee, Jiang, & Klein, 2018 . This section discusses the results of previous studies on relationships among online customer perceptions, customer satisfaction, trust and loyalty and the effects of these on the purchasing decisions of consumers. While presenting the aforementioned literature, firstly studies that demonstrated the relationships among customer loyalty, customer satisfaction and customer trust are included. Then, the section presents the findings of studies that investigated the effects of customer perceptions separately on customer satisfaction, customer loyalty and customer trust. Finally, findings on the comprehensive relationships between online customer perceptions and customer loyalty, satisfaction and trust are provided.

Considering the findings of studies which investigated the relationships among online customer loyalty, satisfaction and trust, it is seen that customer satisfaction and trust affect loyalty directly or through mediating variables. Akbar and James (2014) asserted that customers' online purchasing behaviors, what they understand from the concept of a product and what they have learned through their lives are associated with their attitudes and beliefs. They concluded that perceptions, satisfaction and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

trust directly affect purchasing. Other studies also emphasized that customers' decisions on shopping or not shopping online are affected by perceptions, motivations, learning, attitudes and beliefs (Corbitt, Thanasankita, & Yi 2003; Kim, Ferrin, & Raghay, 2008). Customer satisfaction, trust and loyalty may be increased by accurately determining and suitably managing their expectations and perceptions (Chiu, Hsu, & Chan, 2012). As stated by Reichheld and Schefter (2000), for the management of online shopping sites, it is critically important to know which factors affect the customers and which factors make them loyal customers. Gaining loyal customers for online shopping sites is dependent on several factors, and studies have reported that customer satisfaction, trust and perceptions have a determining role in this issue (Srinivasan et al., 2002; Park & Kim, 2003; Cyr et al., 2007; Kim et al., 2008).

A study which investigated the factors that affect online customer satisfaction reported that electronic service quality, perceived values, customer trust and customer satisfaction are the most significant and effective factors on customer loyalty (Suhartanto, Triyuni, & Leo, 2018). Another study investigated the effects of perceived website usefulness (PU) and customer satisfaction on customer loyalty. While PU affected customer loyalty more after the first purchase, as the number of purchases the customer made increased, there were more effective and determining factors on customer loyalty (Pee et al., 2018). Jaiswal, Niraj and Venugopal (2010) emphasized that at least one purchase should take place for online customer loyalty to be measured. They stated that, if one customer purchases again from the same vendor, they will be a potential loyal customer, and this situation may be directly associated with customer satisfaction and loyalty.

Kim and Peterson (2017) conducted a meta-analysis study and found that online trust was affected by perceived privacy and perceived service quality, while trust affected loyalty and repeated purchase intentions. Song and Lai (2017) determined that customer satisfaction in online shopping had a positive relationship with perceived value that changes based on the online shopping experience. On another study, the researchers studied the factors that affect the trust of customers who shop online for clothes. Accordingly, the showed that customer satisfaction was indirectly effective in shaping online loyalty through the mediating variables of trust and perceived value (Molinillo, Gomez-Ortiz, Pe'rez Aranda & Navarra-Garcia, 2017). Another study that investigated customer loyalty found that customer loyalty was affected by customer satisfaction and trust. It was also reported that customer satisfaction and trust were affected by service quality, which consisted of the sub-components of web design, responsiveness, customization and assurance.

The findings of studies which examined the relationships between customer loyalty and online customer perceptions revealed significant relationships between these and provided important information for organizations who are involved in online commerce. Oypan (2017) emphasized that customers want to feel special while shopping online, and they prefer firms that offer such services more. They also stated that individuals may use their time more efficiently and complete their operations faster with personalized websites. Sherbill (2014) also reported that the sales of online shopping sites that made customizations increased. Öztürk, Coşkun and Dirsehan (2012) emphasized that customization was one of the most important factors in distinguishing those with low e-loyalty and those with high e-loyalty.

Bilgihan (2016) investigated the relationship between the online loyalty of generation Y in online shopping and factors of user experience and brand loyalty. As a result of the study, they found that all three variables affected online loyalty, but the most effective one was trust. Another study which examined online shopping site customer loyalty compared online shoppers in Taiwan and Thailand (Chen, Yen, Pornpriphet, & Widjaja, 2015). They reported that information, system and service quality, including customization, affected customer satisfaction, trust and loyalty. In addition to this, they stated

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

that customer trust and satisfaction also affected customer loyalty. There were significant differences in the perspectives of online customers from two difference cultures on information and system quality. Srinivasan et al. (2002) also emphasized that customization is one of the important perceptions that affect customer loyalty.

Pan, Sheng and Xie (2012) investigated the precursors of online customer satisfaction. As a result, they revealed a conceptual framework that showed that online customer satisfaction was affected by variables in two main group as customer-related and product-related factors. Customer-related factors consisted of customer satisfaction, trust, psychological commitment, loyalty program membership, while product-related factors were perceived value, product quality, perceived fairness, switching cost and brand reputation. They reported that these two groups of factors shaped customer loyalty.

The findings of studies which investigated the relationships between customer satisfaction and online customer perceptions revealed a direct connection. Rowley (2006) argued that online shopping sites should adopt strategies that increase online shopping self-efficacy levels in management of customer satisfaction for their sites. Shih (2004) reported that customers with high self-efficacy levels displayed a more positive attitude towards online shopping, while Sanchez-Franco and Roldan (2005) also stated that e-service quality and self-efficacy would affect satisfaction and trust positively. Thongpapanl and As (2011) reported that information and customization options offered to the customer on online shopping sites positively increased customer satisfaction and shopping intentions. Additionally, it was stated that information provided to the customer is important, but it is not sufficient by itself to motivate the customer for shopping and satisfy them. Consequently, they asserted that customer satisfaction and shopping intentions that develop in a positive way will increase the sales performance of the business.

The findings of studies which investigated the relationships between customer trust and online customer perceptions revealed a direct connection between these except for risk perception. Kim et al. (2008) proposed a decision-making model based on customer trust. As a result of their study, they determined that customer trust was affected by information quality, perceived security and perceived privacy. Moreover, they revealed that risk perception, customer trust and perception of benefit affected the customer's intention for shopping. While risk perception affected customer trust and intention for shopping negatively, the other factors affected these positively. Teo and Liu (2007) examined the factors that affected the trust of online customers in the United States, Singapore and China. They reported that the results for the three countries were not different, and customer trust affected the customer's perceived risk and attitudes. According to their findings, the intention for purchasing decreased by risk perception and increased by positive attitudes.

The findings of studies on the relationships between online customer perceptions and customer loyalty, satisfaction and trust that were conducted in a comprehensive way revealed direct and indirect relationships between these variables. Kurt (2013) investigated the effects of the ethical value perceptions of online vendors on customer loyalty based on the intermediary variables of customer trust and satisfaction. Accordingly, they revealed that perceptions of ethical values consisted of sub-components including security, privacy, honesty and reliability. While ethical value perceptions directly affected customer trust, it affected customer loyalty and satisfaction indirectly. In conclusion, they stated that customer trust affected satisfaction, and satisfaction affected loyalty, while these effects were direct. Kaya and Özen (2012) stated that perceived value has a significant effect on purchasing. Mathwick, Malhotra and Rigdon (2001) also argued that obtaining value is a main goal of purchasing and the basis in all successful transactions. The study conducted by Eid in Saudi Arabia in 2011 found that user interface quality, information quality, perceived security and perceived privacy were variables that affected online

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

customer trust and satisfaction. The researcher reported that online customer satisfaction and trust also affected online customer loyalty. Özgüven (2011) argued in their study that the website that is designed should feel secure for the customer, and for this, all security measures must be taken. While it was seen that customer satisfaction is an important predictor of loyalty, it was emphasized that the security factor for online shopping sites also plays an important role on loyalty.

To sum up the findings of the studies cited above which investigated the relationships between online customer perceptions and customer satisfaction, trust and loyalty, the interactions of customer perceptions with customer trust, satisfaction and loyalty were explained by two models. In the earlier periods, these relationships were explained over a model that states perceptions affect trust, trust affects satisfaction, and satisfaction affects loyalty. In recent years, these relationships were explained by a model that argues that perceptions affect both trust and satisfaction, and trust and satisfaction together affect customer loyalty. Some current studies focused on a model that aimed to explain the relationship of the trust and satisfaction defined in the second model with loyalty through an intermediate variable defined as perceived value. However, there are not enough studies for explaining these relationships over this model.

Online Customer Trust

Customers only shop from individuals, brands, organizations and shops that they trust. This is why managing the sale is important. After this, the exchange continues based on a connection of trust, and the continuity of shopping is achieved. Customer trust on online shopping sites is the belief of the customer that the site and the brand will fulfil their responsibilities during or after shopping and their desire to trust the site in case of a security problem (Erçetin, 2015). In other words, online customer trust consists of the beliefs of customers that the online shopping site will support them when they are defenseless (Hou, 2005; Rewatkar, 2012). While online customer trust is important, the lack of trust of customers in the online shopping website is the main reason why they do not shop online.

As the decisions to be made by the customer during the online shopping process carry risks, online customer trust also has an effect that speeds up decision-making. Studies have reported that the website to be designed should make the customer feel safe, and for this, all security precautions must be taken (Ozguven, 2011). Customer satisfaction is an important determinant of loyalty, while customer trust in online shopping sites plays an important role on loyalty. Studies have defined customer trust as an important factor for customer loyalty (Garbarino & Johnson, 1999; Chaudhuri & Holbrook, 2001). Furthermore, if the customer trusts a site, they are more likely to develop a positive attitude towards the product, pay a good price, stay loyal and mention positive things through word of mouth (Chaudhuri & Holbrook, 2001; Wu, 2013).

Online Customer Satisfaction

Satisfaction has always been a critical issue since the earliest times of trade, and it is becoming increasingly more important. Today, customer satisfaction has a highly significant place in the achievement of competitive advantage by businesses (Bitner & Hubbert, 1994; Su, 2004). Satisfaction is generally defined as the level of the customer's pleasure with and expectations that are met from the good or service they have purchased (Bennington & Cummane, 1998). Online customer satisfaction is the level of satisfaction or dissatisfaction the customer takes from the good or service they have purchased online (Barutcu, 2007). Customer satisfaction is one of the important priorities of online customers that make them ready

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

to shop online (Kuo & Wu, 2012; Wu, 2013). Customer satisfaction plays a key role in repeated purchasing, achieving customer attachment and higher profits by businesses (Reichheld & Schefter, 2000). Online shopping sites must provide customer satisfaction as their customers can distribute information to other customers very easily and fast with the help of the internet. While achievement of customer satisfaction means new customers for a business, dissatisfaction corresponds to loss of customers. This the necessity to satisfy the customer has a vital significance for businesses today. Online shopping sites, just as in conventional commerce, aim to keep their customers.

Customer satisfaction on online shopping sites is accepted as one of the key variables that affect the future purchasing intentions and decisions of customers that shop online. On the other hand, in the case of dissatisfaction of the customer of the online shopping site, the customer stops shopping from online shopping sites and turns towards conventional distribution channel (Barutcu, 2007). While an appeased customer may express their satisfaction to potential customers, a dissatisfied customer poses a risk of expressing their complaints and dissatisfaction to those around them (Dubrovski, 2001). Hence, it is crucially important for online shopping sites to have satisfied customers.

In order to achieve customer satisfaction, online shopping sites need to monitor the process until the product is delivered to the customer and provide support afterwards. As a result of this, the satisfaction level of the online customer will increase, and the customer who is pleased by the good or service they purchased will make their next choice in favor of the same vendor (Leclerc, 2013). As a result of solutions that would not negatively affect the satisfaction and loyalty of customers, online vendors will experience the feeling of permanence as the trust in the website will increase.

Online Customer Loyalty

Loyalty may be explained as a customer's positive attitudes, tendency, likelihood to come back and make purchases from a business due to their belief that the value perceived from a business service is higher than those of alternatives. As drawing new customers towards online shopping sites is costlier in comparison to conventional businesses, loyalty is vitally important in e-commerce in the economic sense. Loyal customers are customers who have formed an emotional connection with the business, and they help presence and recognition of the site's name by making positive recommendations to people around them (Avcikurt & Koroglu, 2006). Therefore, loyalty is seen as an important factor for achieving the success and sustainability of an online shopping site (Dekimpe, Steenkamp, Mellens, & Abeele, 1997; Casaló, Flavián, & Guinalíu, 2008). Online customer loyalty is also seen as a significant competitive advantage in terms of customers' attachment to a business and preference of that business despite the presence of others. This is why it is important for businesses to establish customer loyalty (Çati & Koçoğlu, 2008). Studies have shown that loyal customers stay attached to the brand and the site even if they encounter better options. These customers visit online shopping sites more by 32% and spend 46% more money (Corless; 2019). Establishing customer loyalty is a very difficult process for online shopping sites. The preliminary conditions for this are achieving customer satisfaction and trust and developing long-term customer relations (Eid, 2011).

Customer Perceptions of Online Customers

This section introduces customer perceptions that affect the satisfaction, trust and loyalty of online customers and presents the relationships of these perceptions with customer satisfaction, trust and loyalty.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perception is defined as complex, objective consciousness content that emerges with the contributions of memory and through an affective impression, namely, becoming aware of something through the senses by directing attention towards it. Perception is formed by signals on the nervous system that are created by stimulation of the sensory organs of individuals. Considering it regarding customers who purchase from online shopping sites, it is defined as interpretations that are felt and made before, during and after shopping for a good or service. Customers' development of positive perceptions towards online shopping and sites will lead to the development of e-commerce. This is why revealing the perceptions of customers towards online shopping and designing appropriate e-commerce strategies will allow online shopping sites to conduct their operations efficiently. Furthermore, the perceptions of online customers form a structure that is directly effective on the success of e-commerce. The comprehensive review of the literature showed that, as a result of the interactions of customers with online shopping sites, they developed perceptions of benefit, customer services, control, customization, privacy, risk, security, self-efficacy and value.

Perceived Benefit

Perceived benefit is defined as the perceptions on the benefits customers gain from their shopping process on the online shopping site and as a result of this process (Pavlou, 2003). These benefits may be listed as practicality, easy purchase, opportunity of searching fast and increased options. Online shopping sites should be designed in a practical way for searching for and purchasing products, and this process should be made easier for online customers. Moreover, the options of online customers should be increased by allowing them to look for and buy products faster.

Online shopping sites' provision of detailed information and product diversity to the customer for shopping will increased the perceived benefit they gain as a result of this exchange. After the formation of the perception that the online shopping site's purchasing process for goods or services is beneficial, shopping processes on these websites will increase customer satisfaction and trust (Bhattacherjee, 2001; Devaraj, Fan, & Kohli, 2002; Pavlou, 2003). Customers with feelings of satisfaction and trust will become loyal customers.

Perceived Control

Perceived control refers to the feelings of customers regarding their degree of ability to have control over the content access, searching and processing processes while using the online shopping site with the help of their skills of using information and communication technologies (Rose, Hair, & Clark, 2011).

In the shopping process, there are activities that will develop perceived control in the positive direction. First of these is the feeling of customers to be technically equipped and adequate regarding what they would do when they visit the online shopping site for the first time. Knowing what they would do throughout the shopping process and feeling that they have control in making the purchasing decision are others. Thinking that they can check the information that is provided and feeling that all the process is under control while setting their order are also activities that shape perceived control. One of the advantages of the internet environment is the depth of information provided to customers, and it is important that, through the shopping process, customers feel that they are adequately equipped and have the control. Having a positive perception of control regarding online shopping sites and the shopping process will increase the number of purchases that are made on online shopping sites.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The results of some studies showed that individuals behave more positively when they think they have control over their environment (Ozkara et al., 2017). Therefore, if users have perceived control over the process, it is natural to expect that their trust and satisfaction levels will increase. Perceiving that they can control whatever piece of information they want and will make the best purchasing decision will affect the approaches of customers towards online shopping and their experiences positively. Customers who perceived that control is in their hands will be pleased by the shopping process. Customers with increased satisfaction levels will also have increased trust levels in online shopping.

Perceived Customer Services

Difficulties that are encountered as a result of the impossibility of customers to closely examine and immediately obtain products as in physical stores may only be compensated by advanced levels of customer services. Customer services is an issue that should be prioritized by online shopping sites of all sizes, and it is in the center of the business strategies of e-commerce establishments. While the price and brand of the product create the different in today's commerce, it is expected that this difference will be created by customer services in 2020s. The Customer Report by Microsoft Customer Services stated that almost all of their customers emphasized the importance of customer services. Perceived customer services consist of the feelings of customers that online shopping sites will provide them with the necessary services before and after purchasing not only while conducting their real-time transactions but also for achieving long-term customer services. When today's customers have a question, they want to be answered fast. In the case that they cannot get a response fast, they also quickly move their shopping on the internet towards a different site. Customer services of online shopping sites provide information regarding the usability of the selected products and the status of the orders. They spend efforts to minimize the problems in the provision of the demanded services.

The success of online shopping is determined by the services that are provided during and after the shopping process. The greatest problem is when customers are not sufficiently satisfied by customer services (Bal, 2014). Online shopping sites need to spend an effort to not lose the customer they accessed once. Minimizing the problems experienced in customer services will lead to higher levels of perceived customer services (Eid, 2011). When customer services are provided successfully, customers will be satisfied and develop trust. In turn, this will help keeping the existing customers and drawing new customers. Studies have reported that one of the most effective methods of accessing loyal customers is provision of a high-quality customer service (Eid, 2011).

Accordingly, online shopping sites should also aim to increase this perception by developing a sensitive feedback mechanism based on understanding customer needs and improving services. The customer services of the online shopping site should be accessible for improving this perception, product delivery information should be easily accessible, and detailed product information and answers to frequently asked questions should be certainly provided to the customer.

Perceived Customization

Perceived customization refers to an online shopping site's provision of operational opportunities and platforms for the customer to customize the products or services based on their taste (Srinivasan et al., 2002). Online customers state that the like it very much when online shopping sites present them platforms that feel like directly talking to themselves which allow customization of the colors and visuals on

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the windows that open after logging in as a registered user. When customers log in to online shopping sites as registered users, they have the feeling of being accepted as a customer. It is seen that online customers attach great importance to their feeling of the shopping site as a space that is theirs. This is why online shopping sites need to provide a customized shopping experience to their users to increase sales and achieve customer loyalty (Schrage, 1999). Customization also allows the online customer to focus on the product they want and make a choice fast (Shostak, 1987). Online shopping sites that carry out customization work report that their sales increase (Sherbill, 2014). Customers report that they want to feel special while shopping online, and they prefer firms that provide this opportunity more (Lee & Lin, 2005; Oypan, 2017). Studies have reported that 59% of customers found more interesting products on customized online shopping sites, and 56% visited the sites that recommended products again for purchasing (Saleh, 2018). Customers use their time more efficiently and complete their operations fast in customized sites. Providing customers with a more personalized experience and products that appeal to their interest will lead them to see the website as a special place. With the provision of these advantages, online customers will visit the online shopping site again, and their purchasing probability will increase. As a result of achieving the satisfaction of customers, it will naturally be possible to turn them into loyal customers. Studies reported that one of the most important variables in distinguishing those with low loyalty and those with high loyalty levels is customization (Ozturk et al.,2012).

Perceived Privacy

Privacy is one of the three elements that form the basis of information security. Privacy aims to prevent information from being obtained by unauthorized individuals. Personal and private information is requested for the activities customers perform on online shopping sites. Such information may include name, last name, e-mail addresses, home and work addresses and credit card numbers. Perceived privacy is a customer perception that is based on the extent to which an online shopping site pays importance to prevent the private information of customers from being accessed by unauthorized users or released. Revelation of private information is one of the main sources of anxiety for customers. It is very important for customers that this information they use while shopping is protected (Kim et al., 2008). Studies have revealed that, although online firms promise security, 90% of customers state that they do not trust these firms for the protection of their personal information and feel anxious about this issue (Light, 2001). Online shopping sites should inform their customers regarding how and in what way the personal data they collect for different purposes will be used. It was reported that the vast majority of customers trusted businesses more when they are informed on how their personal information is being used and how their privacy is ensured (Saleh, 2018). Provision of appropriate and sufficient privacy by online shopping sites increases the customer's perceived privacy (Odom, Kumar & Saunders, 2002; Ramanathan, 2011). Customers with high perceived privacy will continue their shopping as satisfied, and then probably, loyal customers.

Perceived Risk

Perceived risk is defined as the uncertainty encountered by customers when they cannot foresee the outcomes of their purchasing decision (Schiffman & Kanuk, 2000). It plays role in shaping customer behavior and is highly important for customers of online shopping sites (Doolin, Dillon, Thompson, & Corner, 2005).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The risk that is perceived by customers is seen to be one of the most significant obstacles in online shopping. Online shopping sites should take the steps necessary to eliminate risk anxiety in their customers by security technologies, awareness campaigns and security policies and reduce perceived risk (Liao & Cheung, 2002; Chih-Chung & Chang, 2005; Lopez-Nicolas & Molina-Castillo, 2008). A study that was conducted in the United States, China and Singapore found that, in all three countries, as the perceived risk of the customers regarding online shopping sites increased, online consumer trust decreased, while perceived risk directly affected the customer's decision to shop or not shop again from the same site (Teo & Liu, 2007). Another study determined that perceived risk that decreased as a result of positive experiences was replaced by perceived advantage (Saydan, 2008). The degree of perceived risk affects customer satisfaction and trust negatively. In order to minimize the perceived risk in customers, online shopping sites should adopt appropriate strategies that will eliminate their anxiousness about the quality, delivery and return of products or services.

Perceived Security

Security refers to mechanisms that prevent unauthorized access to data and systems that include such mechanisms. Perceived security is defined as the perception of a customer that is formed as a result of work that is carried out by online shopping sites to meet security requirements. As online customers cannot interact with the vendor face to face as in the case of conventional shopping, they experience more trust issues (Ha & Stoel, 2009). Trust is at the center of people's interpersonal relationships, and achieving trust in sites that are involved in e-commerce is directly related to technical infrastructure. Sites that have a complicated structure where security features (security policy, security agreement, guarantee of secure shopping) and protection mechanisms (encryption, protection, authentication, secure socket layer technology) are not used lead customers to have trust issues (McKnight & Chervany, 2001). It is known that lack of perceived security is the main reason why several potential customers do not make purchases on online shopping sites. This is why e-commerce sites should create a security plan where security systems work in harmony and provide the infrastructure that is needed for it (Chiu et al., 2012). Shopping sites need to take a set of security precautions for a positive and high perceived security. Some of such precautions include digital certificates to prove the online shopping site is real, secure socket layer (SSL) technology that allows transfer of customer information through a secure platform, 3D security passwords for credit card purchases and usage of firewalls. In addition to these, online shopping sites must have Privacy and Security Policies, and these policies should be presented to customers. If customers feel that the online shopping site aims to meet the security needs of its customers and their goal is to provide a secure shopping platform, their perceived security will increase. As a result of high and positively developed perceived security, customer satisfaction and the sales of the site will increase (Chellappa & Pavlou, 2002; Eid, 2011; Chen, 2012).

Perceived Self-Efficacy

Online shopping self-efficacy is the perception of a customer regarding their skills of online information and price researching and purchasing. In other words, online shopping self-efficacy is the output of the socializing of the consumer, and it is defined as the acquisition of certain consumer skills that contribute to the adequacy of the individual. This variable is an indicator of the extent to which online customers are comfortable in collecting information and shopping on online shopping sites (Chuang,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Lin, & Chin-Chung, 2015). Rowley (2006) emphasized that, in customer satisfaction management, online shopping sites should adopt strategies towards increasing online shopping self-efficacy levels. A study emphasized that customers with high self-efficacy levels display more positive approaches towards online shopping (Shih, 2004). Another study noted that high perceived self-efficacy levels will positively affect the quality of the e-service, satisfaction and trust (Sanchez-Franco & Roldan, 2005). The perceived self-efficacy of customers during online shopping leads them to have a positive shopping experience. This, in turn, affects trust, satisfaction and loyalty positively (Corbitt et al., 2003; Udo, Bagchi, & Kirs 2010; Rose et al., 2011).

Perceived Value

Perceived value is formed as a result of the combination of the cost of the product or service purchased by the consumer and the benefits it provides, and it affects the shopping intention and behavior of the customer (Lai, Griffin, & Babin, 2009). When the value they get compensates or exceeds their expectations, customers decide that the product or service they have purchased is worth purchasing (Srinivasan et al., 2002). Obtaining value is the goal of a basic purchasing process, and perceived value has a substantial effect on purchasing behavior. Customers choose the product that will provide them the best value by comparing the value they obtain to alternatives. This situation is applicable to all commercial operations (Mathwick et al., 2001). In the case that online customers' perceived value regarding a product on an online shopping site is low, they will turn towards the products of competing brands and be more likely to purchase the product from the other site (Parasuraman & Grewal, 2000; Sirdeshmukh, Singh, & Sabol, 2002; Srinivasan et al., 2002). E-commerce sites that work with customers who have low perceived value have to spend more effort to be able to compete with those that work with customers who have high perceived value (Ates, 2018).

Perceived value is one of the perceptions that trigger repeated purchasing behaviors (Parasuraman & Grewal, 2000). Studies have shown that the perceived value of customers who shop online is the most significant variable that predicts customer trust and loyalty. If perceived value is high, online customer trust and loyalty are also high, and this situation affects both the vendor and the customer positively (Flint, Woodruff, & Gardial, 2002; Srinivasan et al., 2002; Chen, 2012). Perceived value is one of the driving forces in the formation of customer trust and loyalty. The feelings of having made a profitable and rational purchase and their efforts were worth it after online shopping will lead to attraction of a loyal customer by creating a positive perception of value. Achieving customer loyalty is a very difficult process, and previous research reported that online shopping sites lose 25% of their users by average each year. Turning customers loyal may prevent a loss of as much as 25% in the profits of the firm. In contrast, when the perception of value that will be formed in the customer is low at the end of the shopping process, the online shopping site will have to spend more effort to stay in the competition (Chen, 2012). Online shopping sites follow up on the constantly changing customer values by acting in this direction and analyze what they and their suppliers could do regarding this matter.

SOLUTIONS AND RECOMMENDATIONS

In order to increase their profit margin, businesses that have online shopping sites need to increase the number of customers who will purchase the services or products they offer. As it is very easy to lose

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

customers on the internet, it is greatly important for online shopping sites to increase the number of customers that are loyal to them. The first thing to do in achieving customer loyalty is achieving customer satisfaction. Customer trust should be earned for customers to become satisfied customers. Trust and satisfaction which affect customer loyalty are also influenced by customer perceptions. Online shopping sites should increase their awareness on how customer perceptions affect this process, work towards managing customer perceptions and adopt relevant strategies.

The great increase in the numbers of security and privacy violations in online shopping shows that the two most important threats for e-commerce today are security and privacy. As it is not possible for vendors and customers to interact directly and in person, security and privacy policies act as a bridge between the two sides. With the help of these policies, customers are able to understand the approach of the online shopping site to these two high-priority issues. Online shopping sites should share information online about the precautions they have taken against threats related to this issue by security and privacy policies.

In order to gain the trust of their customers, online shopping sites should provide the necessary information that customer data are stored in a very secure way and at a very secure place. Online shopping sites may increase their revenues to a significant extent by taking steps that will reduce the fears and perceived risks of their customers regarding online shopping. They may reduce perceived risk and facilitate customer trust by additional precautions using technology such as protection of sensitive customer data, website authentication and risk management. Gaining the trust of online customers will play a great role in increasing sales and reaching the firm's strategic goals.

Online customers have different perceptions in comparison to traditional customers. While shopping, online customers prefer sites that make them feel more special and provide such services more. Online shopping sites may strengthen the bilateral relationships with their customers by collecting information about the activities of the customers on their site and providing customized products and price opportunities based on this information. Online shopping sites may allow customizations based on redirection, prediction and third-party data. The method of customization that is based on behavioral characteristics of customers like the products that check out on the online shopping site, the tabs they browsed, and their purchase history is redirection-based customization. This way, the probability of the customer to purchase may be increased by directing the customer to areas they are interested in. In prediction-based customization, based on orders placed by others, product/service recommendations may be shown to customers with similar profiles. The e-commerce giant Amazon, which achieved 30% increase with the help of recommendation, is one of the firms that benefitted the most from the "frequently bought together" approach, which is one of the best examples of customization. Customization that is based on third party data is a highly practical approach for transmitting the most accurate message to the most accurate audience at the most appropriate time. With the help of these services that are provided, the satisfaction and loyalty levels of customers with high perceptions of customization will increase.

Online shopping sites should make it easier and faster for customers to search for and purchase products in order to increase their perceived benefit. The storefronts that are used in traditional businesses are replaced by the main pages of websites in online shopping. In online shopping, websites with high usability should be designed. This way, the product search and purchase processes of customers will be easier and faster. Additionally, with the help of usable websites, the perceived control of customers that they have the information, resources and capabilities required in the process of using the internet will also increase. In order to increase perceived control and benefit, it is needed to avoid complicated structures that bore their customers, are difficult to use and lead the customer to leave the site in a short

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

time. The customer should be helped in easily accessing products and information related to products with graphics and category titles. As customers cannot see or touch the product itself, the site should include high-resolution and fast-loading images of the product. In-site search and reliably comments and reviews should be provided for products. Hence, in order to increase the perceived benefit of customers, an online shopping site should certainly utilize usability, speed, comprehensive product/service information, visuals and true opinions and reviews.

The perceived value for online customers is influenced by their perceptions of quality, price and sacrifice. In online shopping, if the customers find products more reliable, durable and higher-quality, they will think their online shopping experience is more valuable, and their perceived value will increase. Online shopping sites should provide low prices, develop strategies to motivate customers for shopping and increase product variety.

One of the main reasons for customers' lack of trusty in online shopping sites is related the problems related to customer services that they experience while shopping. Customers are able to solve the problems they encounter in conventional trade with sales representatives. So, they have concerns that they might not find a person that will help them solve the problems they encounter during online shopping for a real-time conversation. Such problems in online shopping are usually solved through phone calls after the fact and e-mails. Instead of this, providing online customer services will be more useful. Knowing that there is a customer services platform from which they can receive support any time they need will contribute to their trust by eliminating their concerns.

At the point customers have purchased online, the responsibility falls on the online shopping site. Fulfilling the promises that are made for increasing customer satisfaction is a golden rule for the continuity of trade in the virtual world. An active and up-to-date 'frequently asked questions' part that covers the topics that might confuse customers should be available on the online shopping site. When customers are able to find the answers to the questions they might have here, they will feel safer. Providing guarantee of original product, quality and return, making payment easier, explaining the return policy and providing technical support will create satisfaction and trust in the customer. Payment processes constitute another factor that shapes customer trust. Secure Socket Layer (SSL) certificates, 3D secure systems, address verification and tokenization are services that may be used for payment. Offering different payment options will increase customer satisfaction. Diversification of payment options such as installments, bank transfer, payment on delivery, PayPal, Payu and Ipara will increase the probability of purchases.

FUTURE RESEARCH DIRECTIONS

This chapter presented the effects of customer perceptions on customer trust, satisfaction and loyalty in a comprehensive manner. The number of studies on online customer perceptions that were newly defined by recent studies such as perceived fairness may be increased, and the interactions of these perceptions may be examined in the model. Moreover, studies may also be carried out by considering the types of each perception within itself. In future studies, moderating effects of additional variables, for example, demographic and psychographic variables on customer trust, satisfaction and loyalty may be studies. Additionally, the effects of customer perceptions in online and offline shopping on customer trust, satisfaction and loyalty may be examined. Researchers may investigate whether or not these effects on customer satisfaction, trust and loyalty differ in two different formats of shopping.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

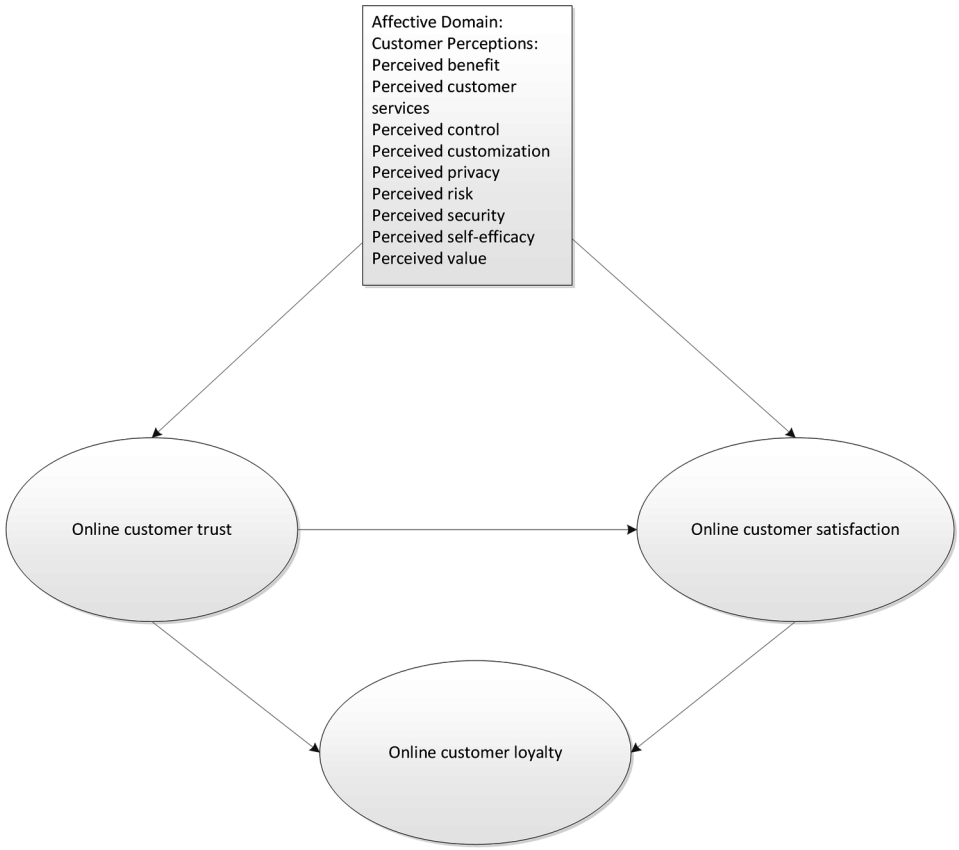
Another topic that may be worth studying is investigating online shopping sites in different sectors and determine whether or not the effects of customer perceptions on customer trust, satisfaction and loyalty differ based on sectors. Researchers could also study the effects of perceptions in real-time online shopping processes on customer trust, satisfaction and loyalty. Mobile devices are frequently preferred by online customers, and mobile commerce (m-commerce) is developing rapidly. Accordingly, online customer perceptions may be studied in terms of e-commerce, m-commerce and omnichannel commerce and comparison may be made.

CONCLUSION

Customer trust, satisfaction and loyalty are important in commerce. However, in difference to conventional commerce, it is seen that customer trust, satisfaction and loyalty in online commerce are affected some customer characteristics whose effects were not well-known before. This study investigated some perceptions in the affective domain that are thought to affect purchasing decisions directly and indirectly in the commercial process between online customers and online shopping sites.

As a result of the study, it was observed that customer trust affects customer satisfaction. Customer trust and customer satisfaction both affect customer loyalty separately and directly, while trust also

Figure 1. Conceptual model



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

affects loyalty indirectly through satisfaction. Customer trust and satisfaction are shaped by customer perceptions as shown in Figure 1. This study investigated the effects on nine perceptions in the affective domain as perceived benefit, perceived control, perceived customer services, perceived customization, perceived risk, perceived security, perceived self-efficiency, perceived privacy and perceived value in the purchasing process.

The important issue for online shopping sites is not how many new customers they gain but how long this relationship will last. Today, responsible customers now know what they want, how much they are willing to pay as a price or how they will receive services. The future of online shopping will be in the hands of businesses that manage the perceptions of customers well and are able to keep up with customer needs.

In conclusion, customers should be approached not as transactions but as relationships, and they should be viewed not in terms of one-time shopping but in terms of increasing the number of loyal customers. Online shopping site that consider customer trust, satisfaction and loyalty, understand the perceptions that affect these completely and develop strategies towards these and are able to manage the affective aspects of customers will be able to preserve their competitive power and sustain their existence and profitability.

ACKNOWLEDGMENT

This research received no specific grant from any funding agency in the public, commercial, or not-for-profit sectors.

KEY TERMS AND DEFINITIONS

Customer Perception: The process where a customer selects, organizes and interprets information to create a meaningful picture of the brand or the product.

Customer Satisfaction: A term that measures how products and services offered by a company meet customer expectations.

Online Customer: An individual who purchases products or services via the internet.

Online Customer Loyalty: The customer's constant preference of the same online shopping site.

Online Customer Trust: The customer's feeling of believing and connecting to the online shopping site they are using without hesitation or doubt.

Online Shopping: Conducting all processes in commercial activities through an online platform.

Online Shopping Site: A website where customers may take part in the presentation of products or services, information, and purchase of such products and surfaces online via the internet.

Chapter 3
Mobile Social Commerce

Christine Balague
Institut Mines Telecom, France

Zhenzhen Zhao
ISC Paris Business School, France

ABSTRACT

S-commerce and M-commerce become buzz word recent years. The social and mobile elements have brought new ways of thinking as well as challenging opportunities in e-commerce. In this chapter, we firstly introduce the concepts of online social commerce, its classifications and social shopping behaviors. Secondly, we analyze the evolution from online social commerce to mobile social commerce. Different case studies are given to demonstrate the concept of mobile social commerce, to precisely define how mobile and social feathers add value to traditional e-commerce.

INTRODUCTION

According to Criteo State of Mobile Commerce report on Q4 2015, percentage of transactions occurring on a mobile device in US, increased from 35% to 44% between Q4 2014 and Q4 2015. Japan, UK and South Korea make up the top three countries ranked by mobile share of transactions, globally. In parallel to this phenomenon, GlobalWebIndex research shows that "digital consumers are comfortable using social networks to find new brands and research products they are interested in buying. Messaging apps like Line and WeChat have pushed beyond simple chat apps to integrate a broad range of commerce options and opportunities for monetization, forming the clear inspiration for Facebook's recent development of Messenger Platform. All these developments mean that social commerce has a bright future". Mobile accounts for 40% of time spent on social media. This context underlines the growing behavior of mobile social shopping and the new topic of interest that represent mobile social commerce applications for companies. Social commerce has begun to be studied in research literature and by companies' experiments; however, few literature exists on the analysis of this new concept of mobile social commerce.

The objective of this chapter is to present an overview of e-commerce with the changing trend of social media and mobility. Towards this new trend, several questions are raised.

- What is social commerce? What is the classification of social commerce?
- How social shopping behaviors affect on e-commerce?
- What is the evolution from traditional e-commerce to online social commerce?
- How mobile features affect on social commerce?

We will focus first on the recent evolution from e-commerce to one line social commerce. Then we will present mobile specificities for social commerce before analyzing different existing social mobile commerce applications. We conclude this chapter with some prospective on mobile social commerce.

BACKGROUND

In the digital era, customer's empowerment increased through four main phases (Labrecque et al., 2013): demand-based at the beginning of 90's, information-based during the contribution economy period, network-based at the end of 2000's with the launch of Facebook, Twitter and You Tube, and finally crowd- based through recent sharing economy. According to these authors, social networks provide a network-based power to customers through network actions and distribution, remixing and enhancement of digital content. This value derives from activities such as content dissemination (e.g., sharing and organizing content through networks), content completion (e.g., comments on a blog post that contribute to previous content, tagging), or content modifications (e.g., repurposing content, such as a video or image meme) in social networks. Social commerce emerged in this context, and social networks platforms tried to monetize their enormous audience by implementing social commerce functionalities (F-stores or Gifts for Facebook, buy button for Twitter). Stephen & Toubia (2010) show the value derived by social commerce networks.

Social Commerce on the Internet is characterized by the convergence between e-commerce and social networks. This phenomenon emerged in the 2000's, with the creation of forums, virtual communities, comments and recommendation tools, and price comparators on the web. Used initially in 2005 by David Beach, Yahoo! Shopping manager, the term "social commerce" is a set of collaborative tools dedicated to e-commerce (products lists, clients' comments, notations, and recommendation systems). A new form of social e-commerce appears in 2008 with Groupon, a successful website during the years following his creation, where individuals can buy at lower prices products and services by grouping their purchases. However, nowadays, Groupon's model has become a source of controversies due to its highly decreasing audience during the last year. In parallel to these new models, social networks and their highly increasing audience provide new opportunities for e-commerce. According to Addshopers, Facebook and Pinterest combine for over 56% of social generated e-commerce at the moment. In this context, social commerce focuses on developing on line sales by using social networks or virtual communities' platforms. From a consumer point of view, social commerce gathers a set of social and participative technologies and capitalize on collaborative web 2.0 usages such as information sharing between web users. Therefore, individuals' purchase is not any more private but becomes a social activity with his/her own community of friends or web users' networks.

Historically, shopping activity is the focus of numerous published papers in marketing literature. From a long time, shopping in real world has been considered as a social experience relying on communications with other persons presenting same centers of interests (Tauber, 1972). In current e-commerce, web consumers are both utilitarian and hedonist, searching for experience (Holbrook & Hirschman, 1982;

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Wolfinbarger & Gilly, 2001). Utilitarian web users aim to quickly find a product on a web site and purchase it easily. Hedonist consumers search for pleasure during web surfing and purchase process. Contrary to traditional shopping, online shopping in often considered as a mediated environment characterized by a low social dimension, based on anonymity and automatism (Hassanein & head, 2007). Answering these issues, social commerce is therefore an increasing phenomenon, and mobile applications allow to largely develop these usages everywhere and every time.

In the next section we will further investigate the concepts from e-commerce to online social commerce, and from online social commerce to mobile social commerce, respectively. Case studies are given to demonstrate the concepts.

MAIN FOCUS OF THE CHAPTER

Issues, Controversies, Problems

As mentioned in the previous section, s-commerce is at the convergence of social networks and e-commerce, topics largely studied in numerous researches. However, social commerce is considered as emerging by practitioners, and research is still needed on this new phenomenon. This section presents two marketing evolutions: (1) from e-commerce to on line social commerce, and (2) from one line social commerce to mobile social commerce. Applications of social mobile commerce are presented afterwards to illustrate this new trend through real cases.

Marketing Evolution

From E-Commerce to Online Social Commerce

Social Commerce Different Models

In this section we present a classification of different social commerce models. According to Marsden (2010), two main interaction modes exist in social commerce: social networks integrated to e-commerce web sites (web users connect with others on the platforms where they buy) or e-commerce integrated in social networks (web users can buy on the platforms they connect with others). However, nowadays, social commerce models classification has become more complex. Therefore we identify four categories.

The first model is social commerce models with collective buying on specific communities of information and recommendation sharing on products and services. One well known example in this category is Groupon, based on a simple process: each day, Groupon web site sends promotional offers to his members (with 50% to 90% of price decrease) on restaurants, shops, spas or other services. This offer is only available when a minimum number of individuals buy it. The social characteristic of this web site is first due to this collective buying process, and second linked to viral marketing tools inviting web users to recommend the offer to their friends' community. Bazando and Tribway constitute also typical examples of this first model. These websites are communities of web users sharing information and recommendations on products which can be bought with cash back (money retribution to the clients of this website). Therefore, more numerous people buy on this web site, more they benefit of cashback. Web users increase their utility by developing the community of buyers on this type of e-commerce site.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The second model of social commerce is characterized by an individual purchase on a traditional e-commerce website, with information and recommendation sharing on specific communities. In this case, web users select products during surfing on the web and create a personalised area on the social commerce community, in which they comment and recommend (or not) the products. On this type of collective platforms, people discover new products by different members, inform themselves on the basis of peer to peer communication and evaluation of product. One example of this social commerce model is Kaboodle, a community of 5 million monthly users around fashion and beauty products. On Kaboodle, users can generate content by using specific tools (drag-and-drop functionality to create styleboards). However, products are bought directly on the traditional e-commerce web site. ProductWiki is another example. Content is completely user generated on this community of consumers commenting and giving reviews on products and services, with links to the e-commerce web sites to buy them.

The third model of social commerce relies on individual online purchase with information and recommendation sharing on social networks. It includes, first, social plugins ("like", "share", "comment") used on e-commerce sites connecting web users to their friends on Facebook, Twitter, Google+, or Foursquare. These social plugins are largely used nowadays in earned media. In this social commerce model, web users share comments or recommendations of products with their friends on social networks, either before or after the purchasing act. Another mechanism is "Facebook connect" to subscribe on a web site services, which is more intrusive (even in opt-in case) on account of the Facebook personal data collected by the e-commerce site. This socla commerce mechanism is frequently used by e-commerce sites as Amazon for instance. A final case is Twitter Dell page @DellOutlet, social network page used as a distribution channel and providing to Dell an amount of sales of more than 7 millions of dollars (in 2010).

The fourth and last category of social commerce model is both collective buying and information and recommendation sharing on social networks. We find in this category F-commerce, including Tab store, Page store and Wallstore on Facebook, or specific area on e-commerce site such as "My social shopping" created in 2012 on C-Discount website, with specific plugins ("I want" and not only "I like") and numerous information sharing and recommendations with friends on social networks.

Social Shopping Behaviour

On a theoretical point of view, several key concepts contribute to a better understanding of social shopping behaviour. First one is buying motivations, largely studied in marketing literature. Tauber (1972) distinguishes personal motivation (such as individual role or entertainment regardless to daily life) and social motivations (such as social experience outside home, communication with persons having same center of interest, pleasure of negotiating). Christodoulides and Michaelidou (2011) have shown that social interaction positively impacts e-satisfaction and e-loyalty and is a key variable of e-commerce. Other trend of research has shown that social commerce is an answer to the lack of social dimension in human-machine interaction on traditional e-commerce web sites. To compensate this fact, web buyers connect with others on virtual communities or social networks to share information ad recommendation on products and services. The sense of community explains this infatuation for community behavior. This psychological construct represents one of the key contributions of sociology research (Tartaglia, 2006). McMillan and Chavis (1986) distinguish the following dimensions: (1) *Membership feeling*: users have a feeling of membership and identification to the community, a personal commitment maintained over time in relation to the community. Users also share a symbolic and common system with other members of the community, translated into behaviors aiming at "singing the praises" and defining the community

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

limits; (2) *The influence feeling:* the individual feels that his place is recognized inside the community, and his presence makes a difference; (3) *The integration and meeting needs feeling*: members consider that the available resources inside the community correspond to their expectations and needs; (4) *the feeling of a shared emotional link*: users feel this emotional link by frequent and high quality interactions, by organizing common events with the community. It also has been showed by Olbrich and Holsing (2011) that social functionalities positively impacts shopping behaviour. Social presence is also a key concept of online social commerce. Another concept is social presence relying on how individuals interacting through a technology, feel they are together (Shen and Khalifa, 2008). Shin and Shin (2011) show that social presence is a key element of buying on online web sites, reinforcing security and confidence. Different vectors of social presence exist, either anthropomorphic (virtual agent, voices, photos or videos) or non-anthropomorphic (text, emailing, consumers' reviews and recommendation search). Information research and peer to peer influence impact on consumers' behavior have been shown by different authors (Chevalier et Mayzlin, 2006 ; Aral et Walker, 2011). Gender impact has also been underlined: for women, shopping is a social activity with implication (Bakewell and Mitchell, 2004), and young women consider socialization and entertainment as important factor of their buying behaviour (Haytko et Baker, 2004). Finally, social psychology theories, and more particularly Cialdini's dimensions (1984) provide a theoretical framework to better understanding social shopping. This author emphasize on six particular dimensions explaining online social shopping. The first one is reciprocity: humans generally aim to return favors or pay back debts and treat others as they treat them. An application in social commerce is a recommendation I will provide on a product because I have previously receive a valuable one from one individual. The second dimension is commitment: we have a deep desire to be consistent. For this reason, once we have committed to something, we are then more inclined to go through with it. In terms of social commerce, we will be more confident toward brands or companies sharing the same values. The third dimension is social proof: we are even more likely to be influenced by people similar to us. Application in social commerce is friends' recommendation. The fourth dimension is "liking": we tend to be more influence by people we like. In social commerce, recommendation or comments from friends (or web users with closed affinity) will influence me. The fifth dimension is authority: we feel a sense of duty or obligation to people in positions of authority, such as experts for instance on social commerce communities. The last Cialdini's dimension is scarcity: things are more attractive when their availability is limited. In terms of social commerce, companies for instance often offer limited edition products on Facebook.

From Online Social Commerce to Mobile Social Commerce

Mobile social commerce (M-commerce) is a type of social commerce conducted over mobile or wireless networks. Mobile commerce services are accessible with fundamentally different presentation, processing, and interaction modalities compared to a desktop computer, such services enable a whole new set of unprecedented service capabilities, including location awareness, context sensing, and push delivery (Kourouthanassis and Giaglis, 2012). It's important to understand how mobile features add values to social commerce and e-commerce in general.

Kourouthanassis and Giaglis (2012) distinguish three main periods of M-commerce. The first one concerns M-portals, between 1997 and 2000, dominated by mobile network operators and m-commerce services bundled into mobile portals. The second period, between 2000 and 2006, focuses on m-internet with e-commerce providers and users enjoying direct internet access through their mobile devices. The

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

third period, from 2000 until now, is characterized by m-applications creating a new m-commerce system. More recently, a new trend emerges in this historical evolution of m-commerce: SoLoMo. Today, location awareness and mobility have added context to even the most ordinary actions. SoLoMo, which stands for Social-Local-Mobile, is a new buzzword being thrown around by marketing teams these years. Social Local Mobile applications open new developments of location-based and context aware services, allowing companies to increase on the market their added value for consumers. For instance, SMS push localized promotions on mobile on customers closed to a shop allow retailers to improve sales. Social features allowing links on social networks or communities allow customer to be in 2.0 social shopping usage.

One challenge for companies is to capture users' attention: a difference between mobile and web services is the usage context (Oinas-Kukkonen and Kurkela, 2003), people often using mobile in a noisy and distracting environments. However, real time contextual information including peer o peer information and recommendation is source of new consumer behaviors on markets. Marketing techniques and teams need to be adapted to this new world. Hui et al. (2013) have shown that mobile promotions aimed at increasing in-store path length can increase unplanned spending.

Another interesting characteristic of social m-commerce relies on QR-code. Abbreviated from Quick Response Code, QR Code is the trademark for a type of matrix barcode (or two-dimensional barcode). A barcode is an optically machine-readable label that is attached to an item and that records information related to that item. Most recently, Starbucks turned to QR codes to create a unique opportunity for engagement with their customers. The company added QR codes to marketing materials for some of their recent products to allow customers to learn more about them. As part of the recent campaign, baristas passed out handy bookmarks with the scannable codes to customers who came in for a cup of coffee. When scanned, the codes directed users to a mobile website with a video and information about Starbucks products. Several Iphone applications include smart shopping lists with integrated access to manufacturers' coupons and support for QR code scanning. In social m-commerce era, these applications add social link and connection with friends of close persons, either on existing social networks (By Facebook connect and Facebook plugins) or on specific users' communities of information and recommendation of products and services. @Walmart Labs develop social mobile applications dedicated to m-commerce and to improve retailer's sales.

Mobile scan possibilities also provide a new way to sell products. For instance, price-comparison applications let users scan the barcode or snap a photo of a physical product (or type or speak a search for one) and then look up the price on the spot and purchase it from the online retailer or directly on mobile, or see its availability and prices at nearby stores with geo-localization maps. One can store the credit card info and pay with the Application. Some applications also include social features such as friends' reviews to help users to make decisions. Aside from price comparisons, some applications can even watch price changes: one can set up an alert for when an item reaches the price you're willing to pay for it.

Social m-commerce relies on mobile payment to pay in real time. For instance, Starbucks uses mobile to improve the customer experience by making it easier for guests to pay for their morning coffee. The company developed Square Wallet, a mobile payment app that was launched in November 2012. The convenience factor of Square Wallet is undeniable. To date, mobile payments have been implemented in over 7,000 Starbucks stores nationwide.

APPLICATION CASE STUDIES OF MOBILE SOCIAL COMMERCE

In this last section we present and comment different user cases and mobile social commerce applications.

Asos: Buy on Facebook Page

ASOS.com is a global online fashion and beauty retailer and offers over 50,000 branded and own label product lines, which is one of the UK's largest online-only fashion and beauty stores. In January 2011, Asos became the world's first fully integrated Facebook Store in Europe, extend the same e-commerce experience to their Facebook Page. The Facebook page offers approximately 1,300 new product lines each week. On their site you can view items, "like" them, share items and comments on certain items on your Facebook profile, see which items your friends have also liked within the store and complete a purchase without ever leaving the ASOS Facebook page.

Said by ASOS community manager: "Millions of our users already interact with ASOS through Facebook, commenting on, sharing and discovering new items. Many of those go on to buy something on one of our sites. Our Facebook Store will allow them to do this directly through Facebook."

While a little slower than shopping on their site, it's a move that will definitely broaden its user base and position it as a brand that is both social media savvy and technologically hip.

LISTIA: ONLINE SOCIAL MARKETPLACE TO EXCHANGE THINGS

Listia is a fun & free online marketplace where users can get rid of things they don't need anymore and get stuff they want in return for free. On Listia, you use credits to bid on auctions instead of cash. You receive credits when you sign up and anytime you give something away, and you use those credits to get free stuff you really want from other users. The more stuff you give away, the more free things you can get.

The guideline is simple:

1. A user lists something they don't want anymore (like an old cell phone).

Figure 2. Screenshots of Listia application

2. Other users bid on the cell phone using credits they received for signing up and listing their own stuff.
3. When the auction ends, the user who bid the highest amount of credits wins!
4. The winner gets the cell phone, and the lister gets credits to use for something else on Listia.

Concerning the mobile elements in Listia, you can take a photo with your device, enter a few brief details and post it to Listia instantly. You can also use the phone to see what people are giving away nearby through the geo location feature, bid on other items and receive instant notifications any time you are outbid or an item you are watching is ending soon. Figure 2 shows the screenshots of usage of Listia.

LivingSocial: Share Shopping Experience

LivingSocial is a deal-of-the-day website that features discounted gift certificates usable at local or national companies. Like Groupon, deals are pushed to mobile device every day, one can click to view the deal and buy directly on your phone.

Concerning other mobile feathers, deals map is designed to check a deal nearby. You'll also be able to browse tons of on-demand, real-time offers on dining experiences, spa treatments, fitness classes, and other nearby deals—ready for immediate use. After one purchase, a QR code is generated to be shown to the merchant. No printing any more.

Concerning the social feathers, each deal can be shared to friends by email, message, Twitter AND Facebook by one click. As a reward, if three of your friends buy the deal, you'll get yours for free.

Figure 3 shows the screenshots of usage of LivingSocial application.

You Loot: User Generated Business

With the slogan "Sell the world around you", You Loot is the world's first ever social commerce marketing app for both consumers and business owners alike. You Loot makes it easy for users to take pictures of the things they want then add their own artistic touch to it before adding the price, the link, and sharing it with friends via email, facebook, twitter, or instagram.

Trace: From Online to Offline – Discover the Cool Things People Buy

With Trace application, one can share the cool things you buy. Make a purchase and after it you can share it with your friends and followers. Just connect your credit or debit card to trace for easy sharing. Users can discover the cool things your friends are buying and the most popular trending purchases. When you see something you want to try, add it to your wish list and Trace will keep you noticed when you are near it. Share all of the cool things you buy with your friends on your favorite social networks including facebook, twitter, and foursquare.

SOLUTIONS AND RECOMMENDATIONS

Social Mobile Social commerce presents several theoretical and managerial implications. Theories on consumer behavior in e-commerce or social networks are mobilized to explain this new emerging trend. On a managerial point of view, the examples show the importance and the specificities of mobile features such as location, QR code, notifications, camera, allowing new interactions between companies and customers. Mobile functionalities constitute interaction tools for direct marketing which has to integrate human-computer interfaces design and user experience design for social mobile commerce.

FUTURE RESEARCH DIRECTIONS

Social M-commerce applications constitute an emerging trend source of numerous future researches direction. The first one concerns ergonomics and user experience in order to develop easy to use and usefulness Human-machine interfaces. Linked to this topic, future research is needed to better understand and measure fluent navigation and flow concept, that Oinas-Kukkonen and Kurkela (2003) has shown as a key variable impacting in mobile applications a positive mobile user experience. Social M-commerce is also a rich area of future research in marketing: how to measure ROI ? Is it more efficient than other

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

distribution channels? How better understanding Social m-shopping behavior? What is the new marketing paradigm of social m-commerce? What about social m-commerce communities and their impact on markets and innovation? Future researches in the sociology field will also lighten on the societal implications of these new technologies, behaviors and form of commerce.

CONCLUSION

Social m-commerce constitutes a new area of opportunities for companies. Based on emerging trend of social networks and peer influence, and existing on line shopping behavior, social m-commerce provides new technological features increasing consumer value on markets and allowing innovation on new services or products. It also opens a new area for future research in different fields such as computer science, technology, sociology and marketing. In 2013, this phenomenon is just at his beginning. However, his potential development in the future years and his consequences in terms of consumer behavior changes and marketing paradigm may be a particular source of attention for both worldwide and very local companies.

ABSTRACT

E-commerce is selling and buying products in online shopping through the internet. When purchasing the products using internet, many security issues arise. These issues are to be addressed effectively and to be resolved. The security issue is an essential part of any transaction that takes place over the internet. Security becomes paramount not only for retailers but for any business that operates via the internet as the popularity of online shopping grows. This chapter focuses security protocols and their achievements in providing effective communication between end-users and business people.

1. INTRODUCTION

The term E-Commerce refers to the use of an electronic medium to carry out commercial transactions via internet. Now a day's E-Commerce is playing a very vital role in online retail marketing and the number of people using this technology is increasing in leaps and bounds all over the world. The security becomes a paramount as the popularity of online shopping grows exponentially in the present days, not only for retailers but for any business that operates via internet. This leads to numerous security risks for consumers. In present scenario, consumer needs to be very cautious while making any kind of online transactions or even surfing the internet. Common mistakes that leave people vulnerable include shopping on websites that aren't secure, giving out too much personal information, and leaving computers open to viruses. This chapter mainly focuses the e-commerce security issues, security threats and guidelines for safe and secure online shopping through shopping web sites. A consumer can very well secure his online shopping to some extend by religiously following the guidelines mentioned in (Niranjanamurthy & Chahar, 2013). Privacy is a state in which one is not observed or disturbed by other people whereas

Security is the action of keeping something secret or the state of being kept secret. So e-commerce security is an essential part of the Information Security Framework which specifically applies to the components that affect e-commerce. These components are generally known as computer security, data security and other realms of the information security framework. The section defines e-commerce and its importance.

1.1 What Is Importance of E-Commerce?

E-commerce has shown enormous growth in the last few years. Sources say that the retail e-commerce sales around world will reach 12.8% in the year 2019 from 7.4% in 2015 (Kalakota & Whinston, 1996). E-commerce is rapidly increasing in the businesses all over the world. E-Commerce usage is moving towards uptrend direction and has received much attention from governments, businesses and regional bodies due to enormous increase of internet users.

The E-Commerce Applications are more popular due to the following reasons

- **Time Consuming Process:** It is very convenient for everyone to shop anytime, anywhere and in any device instead of visiting the shops in person. E-commerce proved its importance based on the fact where time is essence. In the commercial markets, time plays an important role to both the business and consumers. From the business perspective, with less time spent during each transaction, more transaction can be achieved on the same day. As for the consumer, they will save up more time during their transaction. Because of this, Ecommerce steps in and replaced the traditional commerce method where a single transaction can cost both parties a lot of valuable time. With just a few clicks in minutes, a transaction or an order can be placed and completed via the internet with ease. For instance, a banking transaction can be completed through the Internet within a few minutes compared to the traditional banking method which may take up to hours. This fact obviously proves that Ecommerce is beneficial to both business and consumer wise as payment and documentations can be completed with greater efficiency.
- **Product Comparisons:** View different products online is much simpler and more efficient than visiting different stores at different places. So researching the products is much easier by accessing different products online i.e. proper product comparison.
- **Reduction in Capital Investment:** Running an e-commerce business requires far less capital investments compared to owning physical shops. No need to invest on recruiting sales staff, rentals for high end retail stores and unwanted overheads. The only responsibility on you have in an online shop is to promote your website and deliver quality products on-time to the customers.
- **Tremendous Increase of Internet Users:** Electronic commerce, or Ecommerce, which literally means business trading through the Internet, has been around the globe since mid 90s. However, until the recent few years, Ecommerce is getting more and more attention from entrepreneur and consumers, both local and international. One of the main reasons is due to the highly successful operations of some well known names on the Internet, such as eBay, Yahoo and Dell. The sales revenue these companies shown in their annual reports are without doubt, one of the biggest factors why Ecommerce is important in the commercial market nowadays.
- **Business View:** Ecommerce is much more cost effective compared to traditional commerce method. This is due to the fact where through Ecommerce, the cost for the middleperson to sell their products can be saved and diverted to another aspect of their business. One example is the giant computer enterprise, Dell, which practice such a method by running most of their business

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

through internet without involving any third parties. Aside from that, marketing for Ecommerce can achieve a better customer to cost ratio as putting an advertisement on the internet is comparably much cheaper than putting up a roadside banner or filming a television commercial. For Ecommerce, the total overheads needed to run the business is significantly much less compared to the traditional commerce method. The reason due to that is where most of the cost can be reduced in Ecommerce. For example, in running an Ecommerce business, only a head office is needed rather than a head office with a few branches to run the business. In addition to that, most of the cost for staff, maintenance, communications and office rental can be substitute by a single cost, web hosting for the Ecommerce business.

To both the consumers and business, connectivity plays an important part as it is the key factor determining the whole business. From the business point of view, Ecommerce provides better connectivity for its potential customer as their respective website can be accessed virtually from anywhere through Internet. This way, more potential customers can get in touch with the company's business and thus, eliminating the limits of geographical location. From the customer standpoint, Ecommerce is much more convenient as they can browse through a whole directories of catalogues without any hassle, compare prices between products, buying from another country and on top of that, they can do it while at home or at work, without any necessity to move a single inch from their chair. Besides that, for both consumers and business, Ecommerce proves to be more convenient as online trading has less red tape compared to traditional commerce method.

In global market sense, the appearance of Ecommerce as a pioneer has opened up various windows of opportunities for a variety of other companies and investors. For instance, due to the booming of Ecommerce, more and more resources are being directed into electronic securities, internet facilities, business plans and new technologies. In result of this phenomenon, a variety of new markets have emerged from Ecommerce itself giving a boost to the global market. In short, if without any major obstacles, Ecommerce will certainly continue to mature in the global market and eventually, it will become an essential business plan for a company in order to survive and stay competitive in the ever changing market. The next section presents e-commerce applications and its usage.

1.2 E-Commerce Applications and Its Usages

Electronic commerce is the process of conducting commercial transactions electronically over the Internet (Kalakota & Whinston, 1996). This process is carried out primarily in five levels, and the main aspect of e-commerce is a merchant selling products or service to the consumers. There are five major segments under the broader category of e-business. However, the following are some popular e-commerce models used by companies engaged in e-commerce:

- Business to business e-commerce (B2B).
- Business to consumers e-commerce (B2C).
- Consumers to consumers e-commerce (C2C).
- Business to employees e-commerce (B2E).
- Consumer to business e-commerce (C2B).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

1.2.1 Business to Business E-Commerce (B2B)

E-business is the process of conducting business on the Internet. Its scope includes not only buying and selling but also services, fulfilling the needs of customers and collaborating with business partners. Business to business e-commerce is smart business. The opportunity for business to business e-commerce is even greater. A wholesaler may sell products to the retailer. There is advanced e-commerce software which support multi-tier pricing. This helps to set up online stores to offer preferred pricing to some vendors and shared price to others. This includes internet-enabled initiatives of an enterprise to form commercial linkages with another enterprise, dealer, warehouse or manufacturer. In this form of e-commerce, e paperwork and time-to-market get vastly reduced. Throughout the world, this e-commerce mode is the biggest.

In a B2B transaction, the interaction is between businesses. For example, a website that is catching for the steel industry might have facility for buyers and sellers to list their requirements and post their products. It helps them in quickly closing the transactions and the buyer can get quality, material and can choose from different suppliers.

B2B commerce is a growing business in the e-commerce arena- with the increasing use of the internet, more and more business are realizing the commercial advantage of giving business clients a streamlined and easy manner to order products or service online. It facilitates access to the ordering process to only those with whom a concern has a commercial relationship.

Business to Business e-commerce provides small and medium enterprises (SMES) with an excellent opportunity to access new markets, improve customer service and reduce costs. And while hurdles exist, they should be viewed more as speed breakers rather than road barriers. As a medium of information storage and dissemination, the internet has and is emerging a clear winner. Its rate of penetration has far outpaced the growth of other popular media such as newspaper, radio and television. B2B transactions are however relatively high value in nature and organizations are slow to change their traditional systems for the supply chain management. The reasons for the growth in B2B e-commerce are many. In an increasing competitive scenario, e-commerce offers highly attractive cost saving options. The shift to this process is often driven by the needs of buyers. Innovative methods of enhancing B2B and B2C levels of e-commerce include:

- CD-ROM catalogues that are linked to the user's online catalogue, enabling him to browse offline and order online.
- Kiosks placed at physical store locations or in shopping malls to introduce users to the easy online ordering options.
- Extranets to link businesses together that conduct regular business to .business transactions and
- Affiliate programmes to drive business to your commerce site from other content related sites.

B2B e-commerce is expected to be the largest mode of transacting e-business and is a global phenomenon. It involves taking internet enabled initiatives to form commercial links with other enterprises, dealers or manufacturers. In this form of e-commerce, a business firm places orders for supplies with another business firms directly over the Internet. Paperwork and time required for processing the order and delivery of the goods are thus reduced to a great extent.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

1.2.2 Business to Consumers E-Commerce (B2C)

It is for the customers to buy stores from the web. The problem to be recognized in this is to secure payment, using encryption, transaction integrity, quick response, time and reliability.B2C e-commerce involves selling of goods and services to consumers or end users. It allows them to browse the product catalogue, select products or services and complete the order online. In a B2C transaction, the interaction is between a consumer and the preferred business. For example, the most popular site is amazon.com, which is the first online bookseller who has proved a potential competitor to the traditional bricks and mortar booksellers such as Barrens and Noble. In this category of e-commerce, businesses use the internet to offer to consumers sales and services around the world 24 hours a day, seven days a week and 365 days a year, The sites Amazon, Rediff and Uphar are among those belonging to this category. These websites are meant for selling goods directly to consumers through the internet. The two-way accessibility of the internet enables operating companies to directly ascertain customer preference and buying trends. Businesses are using these consumer insights to formulate marketing strategies and offer to the customers what they want and when they want. E-business in this mode significantly reduces the costs associated with intermediaries, service centres and mass marketing campaigns. Since e-commerce makes just in time delivery possible, the supplier does not have to store the goods. He can procure them from the suppliers as and when he gets the order from the buyer through the internet.

B2C is the most popular form of e-commerce, wherein the individuals are directly involved in B2C e-commerce, and businesses use the internet for offering their products or services 24 hours a day through global access. The sites Amazon.com and Rediff are among these. These websites spell goods directly to consumers over the Internet. The two way accessibility feature of the internet enables operating companies to ascertain consumer preferences and buying trends directly.

1.2.3 Consumer to Consumer E-Commerce (C2C)

Here interaction is between consumers to consumer. For example, in sites like e-Buy Bid or Buy.com, Baazi.com which are auction sites, one can virtually sell and buy any goods (either used or new ones). This form of e-commerce is nothing but the cyber version of the good old auction houses. If anyone wants to sell anything, all one has to do is post a message on the site, giving details of the product and the expected price and wait for an interested customer to turn up and buy it. The buyer gets in touch with the seller through the Internet and the deal is crossed once the amount is finalized. Online message boards and barters are also examples of C2C e-commerce.

1.2.4 Consumer-to-Business E-Commerce (C2B)

E-commerce, by empowering the customer, has been strategically redefining business. An example of C2B model of e-commerce is the site Price line.Com, which allows prospective airline travelers, tourists in need of hotel reservations etc. to visit its websites and indicate their preferred price for travel between any two cities. If an airline is willing to issue a ticket on the customers offered price, the consumer can then travel to the mentioned destination at his terms.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

1.2.5 Business to Employees E-Commerce (B2E)

This is concerned more with marketing a corporation's internal processes more efficiently. Customer care and support activities also hold ground. The requirement is that are all self-service with applications on the web that the employees can use themselves.

2. WHY SECURITY PLAY MAJOR ROLE IN E-COMMERCE APPLICATIONS

Security is an essential part of any transaction that takes place over the internet. Customer will lose his/her faith in e-business if its security is compromised. Following are the essential requirements for safe e-payments/transactions –

- **Confidential:** Information should not be accessible to unauthorized person. It should not be intercepted during transmission.
- **Integrity:** Information should not be altered during its transmission over the network.
- **Availability:** Information should be available wherever and whenever requirement within time limit specified.
- **Authenticity:** There should be a mechanism to authenticate user before giving him/her access to required information.
- **Non-Reputability:** It is protection against denial of order or denial of payment. Once a sender sends a message, the sender should not able to deny sending the message. Similarly the recipient of message should not be able to deny receipt.
- **Encryption:** Information should be encrypted and decrypted only by authorized user.
- **Auditability:** Data should be recorded in such a way that it can be audited for integrity requirements.
- Major security measures are following:
- **Encryption:** It is a very effective and practical way to safeguard the data being transmitted over the network. Sender of the information encrypt the data using a secret code and specified receiver only can decrypt the data using the same or different secret code.
- **Digital Signature:** Digital signature ensures the authenticity of the information. A digital signature is an e-signature authentic authenticated through encryption and password.
- **Security Certificates:** Security certificate is unique digital id used to verify identity of an individual website or user.

3. E-COMMERCE THREATS

Threats: Anyone with the capability, technology, opportunity, and intent to do harm.Potential threats can be foreign or domestic, internal or external, state-sponsored or a single rogue element. Terrorists, insiders, disgruntled employees, and hackers are included in this profile (President's Commission on Critical Infrastructure Protection).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1.

Concern	2001	2000
Loss of Privacy/confidentiality, data misuse/abuse	28%	25%
Cracking, eavesdropping, spoofing, root kits	25%	20%
Viruses, Trojans, worms, hostile ActiveX and Java	21%	26%
System unavailability, denial of service, natural disasters, power interruptions	18%	20%

1. Intellectual property threats -- use existing materials found on the Internet without the owner's permission, e.g., music downloading, domain name (cyber squatting), software pirating
2. Client computer threats
    a. Trojan horse
    b. Active contents
    c. Viruses
3. Communication channel threats
    a. Sniffer program
    b. Backdoor
    c. Spoofing
    d. Denial-of-service
4. Server threats
    a. Privilege setting
    b. Server Side Include (SSI), Common Gateway Interface (CGI)
    c. File transfer
    d. Spamming

Countermeasure

A procedure that recognizes, reduces, or eliminates a threat:

1. Intellectual property protection
    a. Legislature
    b. Authentication
2. Client computer protection
    a. Privacy -- Cookie blockers; Anonymizer
    b. Digital certificate
    c. Browser protection
    d. Antivirus software
    e. Computer forensics expert
3. Communication channel protection
    a. Encryption
    b. Public-key encryption (asymmetric) vs Private-key encryption (symmetric).
    c. Encryption standard: Data Encryption Standard (DES), Advanced Encryption Standard (AES).
    d. Protocol

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. Secure Sockets Layer (SSL)
5. Secure Hyper Text Transfer Protocol (S-HTTP)
    a. Digital signature.
    b. Bind the message originator with the exact contents of the message.
    c. A hash function is used to transform messages into a 128-bit digest (message digest).
    d. The sender's private key is used to encrypt the message digest (digital signature).
    e. The message + signature are sent to the receiver.
    f. The recipient uses the hash function to recalculate the message digest.
    g. The sender's public key is used to decrypt the message digest.
    h. Check to see if the recalculated message digest = decrypted message digest.
6. Server protection
    a. Access control and authentication
    b. Digital signature from user
    c. Username and password
    d. Access control list
    e. Firewalls
    f. International Computer Security Association's classification:
7. Packet filter firewall: checks IP address of incoming packet and rejects anything that does not match the list of trusted addresses (prone to IP spoofing).
8. Application level proxy server: examines the application used for each individual IP packet (e.g., HTTP, FTP) to verify its authenticity.
9. Stateful packet inspection: examines all parts of the IP packet to determine whether or not to accept or reject the requested communication.

4. SECURITY ISSUES IN E-COMMERCE APPLICATION

4.1 E-Commerce Security Threats

The direct threats to e-commerce servers can be classified as malicious code threats and transmission threats. (Gautam, 2014). Malicious or rogue programming code is introduced into the server in order to gain access to the system resources. Very often, the intent of malicious code attacks is to cause large scale damage to the e-commerce server. With transmission threats, the threats and risks can be classified as either as active or passive. With passive threats, the main goal is to listen (or eavesdrop) to transmissions to the server. With active threats, the intent is to alter the flow of data transmission or to create a rogue transmission aimed directly at the e-commerce server.

1. **Malicious Code Attacks: Viruses and Worms:** A virus attaches itself to executable code and is executed when the software program begins to run or an infected file is opened. However, a worm does not need a host to replicate. Rather, the worm replicates itself through the internet, and can literally infect millions of computers on a global basis in just a matter of hours. Worms by themselves do not cause damage to a system like a virus does. However, worms can shut down parts of the internet or ecommerce servers, because they can use up valuable resources of the internet, as well as the memory and processing power of servers and other computers.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2. **Trojan Horses:** A Trojan horse is a piece of programming code that is layered behind another program, and can perform covert, malicious functions. For example, your e-commerce server can display a "cool-looking" screen saver, but behind that could be a piece of hidden code, causing damage to your system. One way to get a Trojan horse attack is by downloading software from the internet. Make sure that whatever software is downloaded comes from an authentic and verified source, and that all defense mechanisms are activated on your server.
3. **Logic Bombs:** A logic bomb is a version of a Trojan horse, however, it is event or time specific. For example, a logic bomb will release malicious or rogue code in an e-commerce server after some specific time has elapsed or a particular event in application or processing has occurred.
4. **Transmission Threats - Denial of Service Attacks:** With a denial of service attack, the main intention is to deny your customers the services provided on your e-commerce server. This happens when a massive amount of invalid data is sent to the server. Because the server can handle and process so much information at any given time, it is unable to keep with the information and data overflow. As a result, the server becomes "confused", and subsequently shuts down. Ping of death: With a ping of death attack, a massive data packet is sent to the server. As a result, the memory buffers of the e-commerce server are totally overloaded, thus causing it to crash. SYN flooding: A SYN flood is a form of denial-of-service attack in which an attacker sends a succession of SYN requests to a target's system in an attempt to consume enough server resources to make the system unresponsive to legitimate traffic Ip spoofing: The intent here is to change the source address of a data packet to give it the appearance that it originated from another computer. With ip spoofing, it is difficult to identify the real attacker, since all e-commerce server logs will show connections from a legitimate source.
5. **E-Commerce Security Tools Firewalls (For Software and Hardware):** A firewall is a system designed to prevent unauthorized access to or from a private network. Firewalls can be implemented in both hardware and software, or a combination of both. Firewalls are frequently used to prevent unauthorized internet users from accessing private networks connected to the internet, especially intranets. All messages entering or leaving the intranet pass through the firewall, which examines each message and blocks those that do not meet the specified security criteria. Public key infrastructure: A pki (public key infrastructure) enables users of a basically unsecure public network such as the internet to securely and privately exchange data and money through the use of a public and a private cryptographic key pair that is obtained and shared through a trusted authority. Encryption software: Encryption software is software whose main task is encryption and decryption of data, usually in the form of files on (or sectors of) hard drives and removable media, email messages, or in the form of packets sent over computer networks. It is a very effective and practical way to safeguard the data being transmitted over the network. Sender of the information encrypts the data using a secret code and specified receiver only can decrypt the data using the same or different secret code. Digital signature: Digital signature ensures the authenticity of the information. A digital signature is a e-signature authentic authenticated through encryption and password. Security certificates: Security certificate is unique digital id used to verify identity of an individual website or user.
6. **Guidelines to Shop Online Safely Shop at Secure Web Sites:** A secure web site uses encryption and authentication standards to protect the confidentiality of information sent during web transactions. A secure web page can be identified using following guidelines:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

a. The url of a secure webpage begins with the letters https.
b. Ensure that the address bar has some element of green in it. Different browsers use different elements. Microsoft's internet explorer - background is shaded green. Apple's Safari and Google's Chrome - https is shaded green.
c. Look for a closed padlock. If that lock is open, you should assume it is not a secure site. Most web browsers display the 'lock' icon somewhere in the window of the browser. Microsoft's internet explorer displays a lock in the lower-right of the browser window. Mozilla's Firefox displays the lock icon in the lower-left corner of the window. The lock is not just a picture. You can click or double click on it to see details of the site's security. This is important because some fraudulent sites are built with a bar at the bottom of the page to imitate the lock icon of your browser.

7. **Investigate About the Web Site Before You Order:** Avoid doing business with unknown web sites. If you are going to deal with a web site for the first time, do your homework before buying their products. Start business with an unknown website by ordering something inexpensive. This will help you judge the authenticity of the web site. Reliable web sites should advertise their physical business address and contact number, either customer service or an order line. Call the phone number and ask questions to determine if the business is legitimate.
8. **Read the Web Site's Privacy and Security Policies:** Every reputable online web site offers information about how it processes your order. It is usually listed in the section entitled ——privacy policy (Shopping Online, 2014). Reputable companies will be open about how they collect data from you and what they do with it. Many now also belong to web-seal approval or trust mark programs that set out guidelines on the treatment of your information.
9. **Use Safe Payment Options:** Credit cards are generally the safest option because they allow buyers to seek a credit from the issuer if the product isn't delivered or isn't what was ordered (StaySafeOnline, n.d.) Also, unlike debit cards, credit cards may have a limit on the monetary amount you will be responsible for paying if your information is stolen and used by someone else. Never send cash through the mail or use a money-wiring service because you'll have no recourse if something goes wrong. Don't forget to review return policies. You want a no-hassle ability to return items.
10. **Use Virtual Credit Cards as Needed:** Virtual credit cards are temporary payment cards, and come in the form of a physical plastic card, or as a generated credit card number, and they're separate from your bank information (ITProPortal, n.d.). This type of disposable credit card payment method contains a pre-set spending amount, has a shorter-than-usual expiration date, and is equivalent to a regular credit card for most payments purposes. Virtual credit card payments are usually charged to your credit or debit card, rather than directly to your bank account, essentially offering an additional layer of protection. When you pay with a virtual credit card, your banking information remains separate from your individual purchase, thus ensuring if the card number is stolen, hackers cannot access your accounts or re-use the card fraudulently.
11. **Disclose Only the Bare Facts When You Order:** When making a purchase online, there is certain information that you must provide to the web merchant such as your name and address. Often, a merchant will try to obtain more information about you. They may ask questions about your leisure lifestyle or annual income. Be alert to the kinds of information being collected to complete the transaction. Make sure you think it is necessary for the vendor to request that information. Remember, you only need to fill out required fields on a vendors checkout form. Before providing personal or financial information, make sure you understand how your information will be stored

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and used. The information you provide is used to target you for marketing purposes. It can lead to "spam" or even direct mail and telephone solicitations. Don't answer any question you feel is not require to process your order. Often, the web site will mark which questions need to be answered with an asterisk (*).

12. **Keep Your Password Private:** You will usually be asked for a password before you make an online payment. This is to help keep your personal details private. (BBC, 2013). Make sure you use a strong password - one that is a combination of letters (upper and lower case), numbers and symbols. Never reveal your password to anyone. When selecting a password, do not use commonly known information, such as your birthdate, mother's maiden name, or numbers from your driver's license or social security number. Do not reuse the same password for other sites, particularly sites associated with sensitive information.
13. **Don't Fall for "Phishing" Messages:** Phishing is the process whereby someone attempts to obtain your confidential information, such as your passwords, your credit card number, your bank account details or other information protected by the data protection act. A phishing attack can be in the form of an official looking email or instant message, maybe directing you to an official looking website, or it could be an official sounding phone call. Recognizing a phishing attack There are number of clues that may indicate an email or website is not genuine such as:
    a. Suspicious email links. Try hovering your mouse over a link without clicking on it. If the address that pops up does not match the link address as it is written in the email, it's a clear indication of a phishing email.
    b. A link to a genuine website which takes you somewhere else.
    c. Spelling or grammatical mistakes, inappropriate use of capitals or exclamation marks, formatting errors.
    d. A generic email greeting.
    e. Claims that you need to act immediately to prevent something bad from happening (for example, your account will be deleted or your email will be lost).
    f. Requests for personal information, such as your password or bank account number However, you should always be wary as some phishing attacks may be sophisticated and difficult to spot. You should refuse to disclose confidential information until you have checked to your own satisfaction that the request is justified and legitimate and has been made by a genuine person or organization. There are various phishing filters, like smart screen filter in internet explorer, which will help protect you from phishing sites by warning you when it detects a distrustful website.
14. **Always Print or Save Copies of Your Orders:** Print and save records of your online transactions, including the product description, price, online receipt, terms of the sale, and copies of any email exchange with the seller. (StaySafeOnline, n.d.). If you cannot print one off, take a screenshot as a form of proof of purchase. We recommend you print out or save a copy of the web page(s) describing the item you ordered as well as the page showing company name, postal address, phone number, and legal terms, including return policy. Read your credit card statements as soon as you get them to make sure there aren't any unauthorized charges. If there is a discrepancy, call your bank and report it immediately
15. **Turn Your Computer Off When You're Finished Shopping:** Many people leave their computers running and connected to the internet all day and night. This gives scammers 24/7 access to your

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

computer to install malware and commit cybercrimes. To be safe, turn off your computer when it's not in use.

16. **Find Out About Billing, Guarantees, Cancellation Policies, Shipping and Delivery Charges Before You Buy:** You can look for following information:
    a. Packaging costs, delivery costs etc.
    b. Whether you will be billed before or after delivery of the products.
    c. Whether you can track the item from the moment of purchase to arrival at your door - this will help alert you of any hiccups in the delivery.
    d. Whether the product comes with a guarantee or warranty for defects etc.
    e. How you can return the product if it doesn't work or meet your expectations - look for information on the site about cancellations, returns and refunds. Print off a copy for future reference.
    f. Who will bear the cost of returning the item (postage, fees etc.)
17. **Know How Online Auctions Operate:** Online auctions connect buyers and sellers, allowing them to communicate in a bidding process over items for sale (Privacy Rights Clearinghouse, 2000). For the most part, online auction sites are a safe way to exchange goods. But it makes sense to be cautious and aware. Online auctions can be a lot of fun and can also help you find good deals. They also attract scammers. Scammers will often try to get you to deal outside of online auction sites. They may claim the winner of an auction that you were bidding on has pulled out and offer the item to you. Once you have paid, you will never hear from them again and the auction site will not be able to help you. Following are the guidelines for participating safely in online auctions:
    a. Always conduct transactions within the auction website and avoid private contact with buyers or sellers-scammers will often use this ploy to 'offer a better deal'.
    b. Keep printed and/or electronic records of all bids, item descriptions, emails to and from the seller, and transaction records or receipts.
    c. If the website uses a feedback rating system, check all comments left by previous buyers and sellers.
    d. Use a secure payment method.
    e. Avoid money transfers and direct debit, because they can be open to abuse.
    f. Consider using the insurance offered by the auction facility.
    g. Check the information on auction websites to help potential buyers and sellers.
    h. Take the time to read the information about ways to reduce the risk on the auction site and the terms and conditions of contracts entered into by bidders and sellers.
    i. Learn a site's return policy, as it may be difficult to return merchandise bought at auction. It's critical to check the policy, because you may be required to follow the seller's refund policy, rather than that of the auction site.
18. **Be Aware of Dynamic Pricing:** Dynamic pricing is a blanket term for any shopping experience where the price of an item fluctuates frequently based on complicated algorithms (CSMonitor, n.d.). Some online retailers use dynamic pricing to engage in price discrimination by charging different prices to different consumers for identical goods or services. While online shopping enables consumers to easily compare prices, it also allows businesses to collect detailed information about a customer's purchasing history and preferences. Online stores can use that information to customize the prices they charge you. Online merchants can easily implement dynamic pricing by placing cookies on a customer's computer which will track the user's past interactions with the site. By using this information, sites can customize their interactions based on your past activities. Online

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

stores can read the cookies on your browser to determine what products or services you searched for and bought and how much you paid for them. This information helps them to predict how much you might they visit the issuer‘s site. As a rule of thumb, assume all shared wi-fi networks are unsafe for your sensitive data. Everything from an online bank statement to a gmail account can be compromised when surfing the web on a shared wi-fi network. It’s nearly impossible to accurately gauge how secure a wi-fi network is, and thus it’s best to err on the side of caution. (Kamanec, 2013).

19. **Protect Your Online Identity on the Social Front:** Online purchasing is getting more and more social, with 50 per cent of web sales projected to occur via social media by 2015 (Kamanec, 2013). Each time you join a new site through the “login with face book” option, you’re extending your online identity further. In fact, an abundance of sites will first prompt you to become a member not by email, but by connecting a social media account. Is it a direct connection? Technically, no. Will it be used to shape your online identity? Absolutely. Your social media presence defines your digital footprint to the point where companies are looking to use your social media identity to combat online payment fraud and your social signals to tackle identity fraud in the near future. Once you realize that the majority of your online activity is interconnected, you can better defend yourself from making thoughtless choices that may endanger your data. Just like you shouldn’t post something you don’t want your employer to see on face book, you also shouldn’t post anything you don’t want a hacker to see, like a picture of your driver’s license or passport, anything with a home address and any snapshots that include a visible credit card or credit card number.

5. SECURITY PROTOCOLS IN INTERNET

Following are the popular protocols used over the internet which ensures security of transactions made over the internet.

5.1 Secure Socket Layer (SSL)

It is the most commonly used protocol and is widely used across the industry. It meets following security requirements –

- Authentication
- Encryption
- Integrity
- Non-reputability

“https://” is to be used for HTTP urls with SSL, where as “http:/” is to be used for HTTP urls without SSL.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

5.2 Secure Hypertext Transfer Protocol (SHTTP)

SHTTP extends the HTTP internet protocol with public key encryption, authentication and digital signature over the internet. Secure HTTP supports multiple security mechanism providing security to end users. SHTTP works by negotiating encryption scheme types used between client and server.

5.3 Secure Electronic Transaction

It is a secure protocol developed by MasterCard and Visa in collaboration. Thereoritically, it is the best security protocol. It has following components:

- **Card Holder's Digital Wallet Software:** Digital Wallet allows card holder to make secure purchases online via point and click interface.
- **Merchant Software:** This software helps merchants to communicate with potential customers and financial institutions in secure manner.
- **Payment Gateway Server Software:** Payment gateway provides automatic and standard payment process. It supports the process for merchant's certificate request.
- **Certificate Authority Software:** This software is used by financial institutions to issue digital certificates to card holders and merchants and to enable them to register their account agreements for secure electronic commerce.

5.4 How to Minimize Security Threats

1. Perform a risk assessment ⋄ a list of information assets and their value to the firm
2. Develop a security policy ⋄ a written statement on:
3. what assets to protect from whom?
4. why these assets are being protected?
5. who is responsible for what protection?
6. which behaviors are acceptable and unacceptable?
7. Develop an implementation plan ⋄ a set of action steps to achieve security goals
8. Create a security organization ⋄ a unit to administer the security policy
9. Perform a security audit ⋄ a routine review of access logs and evaluation of security procedures

5.5 Security Measures

1. **Secure Electronic Transaction (SET) Protocol:** Developed jointly by MasterCard and Visa with the goal of providing a secure payment environment for the transmission of credit card data.
   SET payment transaction:
   - A shopper makes a purchase and transmits encrypted billing information with his/her digital certificate to the merchant.
   - The merchant transfers the SET-coded transaction to a payment card-processing center.
   - The processing center decrypts the transaction.
   - A certification authority certifies the digital certificate as belonging to the shopper.
   - The processing center routes the transaction to the shopper's bank for approval.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2.

Features	*SSL*	*SET*
Encryption of data during transmission	Yes	Yes
Confirmation of message integrity	Yes	Yes
Authentication of merchant	Yes	Yes
Authentication of consumer	No	Yes
Transmission of specific data only on a "need know" basis	No	Yes
Inclusion of bank or trusted third party in transaction	No	Yes
No need for merchant to secure credit card data internally	No	Yes

- The merchant receives notification from the shopper's bank that the transaction is approved.
- The shopper's payment card account is charged for the transaction amount.
- The merchant ships the merchandize and transmits the transaction amount to the merchant's bank for deposit.

2. **Disposable Credit Numbers:** One-time-use credit card numbers (private payment number) are transmitted to the merchant
   a. Register with American Express or Discover
   b. Download software (a Private Payment icon tray will be displayed on the screen)
   c. Shop online
   d. Click on the Private Payment icon
   e. Log-in
   f. Select the credit card to be used
   g. View unique, one-time-use credit card number and expiration date
   h. Enter the one-time-used credit card number and expiration date into merchant's standard form

6. ONLINE BANKING APPLICATION (E-COMMERCE AND BANKING INDUSTRY)

Structure:

1. Objectives
2. Introduction to Electronic Commerce and Banking
3. Changing Dynamics in the Banking Industry
4. Home Banking Implementation Approaches
5. Open versus Closed System
6. Management Issues in Online Banking

6.1 Objectives

The motive of this chapter is to present an introduction to Electronic Commerce and Banking Industry and within that framework the key e-banking concepts, changing dynamics, implementation approaches, and management issues in the banking industry are discussed.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

After going through this lesson, you will be able to:

- Describe the concept of electronic banking.
- Explain the changing market structure and customer needs in banking industry.
- Differentiate between online banking and electronic banking.
- Discuss the management issues related to online banking.
- Describe some of the marketing and pricing related issues in online banking.

6.2 Introduction to Electronic Commerce and Banking

The decade of 90s has witnessed a sea change in the way of doing banking. The scenario has been improving at a very fast pace as electronic commerce (e-commerce) is receiving more and more attention in the banking industry. Technology has made a tremendous impact on this industry by reducing operating costs and also by providing adequate customer services. To some extent, the intense interest of bankers in electronic banking (e-banking) reflects a more general interest in the role of the internet as a vehicle for commercial activity. At its core, e-banking involves the collection, storage, transfer and processing of information assets and internet is an incredibly powerful and efficient tool for handling these information processes.

'Anywhere banking' and *'Anytime banking'* have become a reality. There is no specific online banking region to which the transactions are limited. Bookkeeping is simplified and automated and so is tax computation. Bills are paid with a minimum of effort. E-banking offers a wider outreach for banking institutions. E-banking is most useful when it saves the consumer time and money. It is particularly useful for those who have a lot of bills to pay and already use a personal financial program like Intuit's Quicken or Microsoft Money. The need for e-banking is continuously increasing as more and more consumers gain addiction to doing their banking transaction the quick and easy way. Moreover, since e-banking business is secure, many commercial concerns are also turning to doing their banking via the Internet.

E-banking makes use of electronic currency. Check cards or debit cards, smart cards or stored-value cards, digital cash and digital checks are the different types of electronic currency. If anyone uses a check card to make purchases, the funds are transferred immediately from his/her account to the company's account. Smart cards have a specific amount of credit embedded in it. The chip in the card contains both personal and financial information of the user. Digital cash is one way of allowing consumers make purchases over the Internet instead of using a credit card. Digital checks are used with electronic bill paying services. Consumers can use personal finance software packages or they can use software provided by a bank.

Loans are now marketed as products, with a number of value–added services attached to them. Banks are selling mutual funds, providing education loans, car loans, home loans, credit cards and debit cards. There have been associations with petroleum companies, airline companies, hospitality industry, and media houses to promote products and services.

Restructuring in the banking arena is already in progress. If banks are talking anytime, anywhere service for their customers, they are changing their organizations to fit in with the new reality of making them more productive and function driven. Public sector banks are also reorienting themselves to change their profile to be able to raise fresh capital from the market.

The Internet is an extremely efficient device for banks of all sizes to collect and to manage information in order to meet the various financial needs of individuals and businesses, in particular by integrat-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ing services or "bundling" them together. On one hand, the Internet allows financial firms of different sizes to enter markets and reach customers previously out of reach to them. On the other hand, there are substantial economies of scale and scope in data storage and data processing, and larger banks are better positioned to exploit these scales and scope economies than smaller banks.

6.3 What Is E-Commerce and E-Banking?

E-commerce may broadly be defined as all the transactional commerce conducted electronically between businesses and other businesses (B2B), between businesses and their end-customers (B2C) and within an enterprise, over the internet, extranets and intranets (Kalakota & Whinston, 1996). E-commerce or online commercial transactions has emerged as a major economic force. It is not just the purchase of goods online, but also the electronic exchange of services, including information and knowledge, such as legal advice, archival data, design and financial services. Information, its provision and access, is as critical an issue in e-commerce as it always has been in any sort of commerce. Online access is already a requirement for full social, economic and educational participation in the light of stated government and private sector goals of electronic service delivery.

Electronic banking is using electronic means to transfer funds directly from one account to another. Electronic banking is a system that enables bank customers to access accounts and general information on bank products and services through a personal computer or other intelligent device.

Some electronic banking services are ATMs, direct deposit and withdrawal services, pay by phone systems, point-of-sale transfer terminals, Web banking or PC banking services, even banking from mobile phone. Electronic banking offers consumers the convenience of accessing and transferring funds between their accounts, paying their bills and other purchases, twenty-four hours a day, seven days a week.

A fully-integrated bank e-commerce system combines a powerful and flexible enterprise server with software and services that can take full advantage of already accumulated information such as consumer demographics, credit records, risk profiles and account histories to help exploit customer preferences, accelerate speed to market and improve the bottom line. Forward-looking banks are focusing on the need for e-banking, personalized data and customer service, and the highest possible network security. E-banking has had a noticeable impact on bank performance.

6.4 E-Commerce Banking: Technological Benefits and Barriers

New technologies offer unprecedented levels of communication and expanding possibilities for equal information access and independent living. Digital technologies can reduce the expense and difficulty of providing information.

The barriers to e-banking may be security and privacy concerns, particularly with credit cards, shipping and delivery costs, time consuming, difficulty of finding websites/products, complexity of ordering process. Trust and accountability are the main requirements. E-banking cannot be expected to suit all users, and may present serious access barriers to some people with disabilities, but for other people it represents independence and equality.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

6.5 Changing Dynamics in the Banking Industry

Globalization and liberalization of financial markets may have paved the way to increased access to cross-border banking, but the significant advances in electronic technology are what have accelerated access to anonymous and instantaneous cross-border banking. Even without the liberalization of financial markets, the new technologies have permitted this to occur.

With the development of technologies in the banking industry, there has been a major change in the banking system and in the way banks strive for increased profitability.

In the past, the banking industry was mainly concerned with asset quality and capitalization, but today performing well on asset quality and capitalization is not sufficient. A thorough understanding of competitive environment and the new ways to increase revenue are the basic desires of modern banks. and new competitors. E-banking can meet the customers' changing needs and a broad range of banking requirements by having:

- Available 24 hours a day, 7 days a week.
- Ability to access financial information.
- Query capability for finding particular payments or deposits.
- Customized account reporting options.
- Details of accrued interest and charges on individual accounts.
- Option to make payments directly from one's bank account to any other's account.
- Batch processing of credit card transactions.
- Transaction details in a file that can be interfaced with a variety of accounting packages.
- Capacity to group and process one-to many payments such as creditor payments, salaries etc.
- Ability to process direct debit transactions.
- Option to post-date payments for a future date.
- Features to create payments in external software packages, such as payroll and accounting packages, for processing by the bank.
- Provision of weekly market commentary and daily exchange rate information.

In addition, for international trading, e-banking may offer a full suite of international transactions including:

- Foreign Currency Account Transfers
- Telegraphic Transfers
- International Cheques (Bank Drafts)
- Letter of Credit Application and Amendment
- Guarantee and Shipping Company Guarantee
- Collections

6.6 E-Commerce and New Technology Based Banking Services

Imagine the convenience of everyday banking without having to leave the office. Imagine not having to write cheques, and post payments every month. With just a personal computer, a modem and bank of electronic banking, one can effectively

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Following are the distinct factors contributing to the new competitive environment:

- E-commerce and changing consumer needs – Absolute essentials for competitive banking
- E-commerce and new technology-based banking services
- Optimization of branch networks in order to reduce cost
- Banking and bank regulation - Potential challenges for regulatory policy
- E-commerce and trends in banking industry

6.7 E-Commerce and Changing Consumer Needs: Absolute Essentials for Competitive Banking

In this changing environment, consumers' requirements are changing substantially. Now Customers want to access account related information, download account data for use with personal finance software products, transfer funds between accounts, and pay bills electronically. The bank must be able to safeguard customer information and personal privacy. Consolidation of the banking industry and the expanding scope of products offered by financial service firms means that the industry will be responsible for maintaining and safeguarding huge databases containing extensive information on individuals.

In such an intensely competitive networked banking marketplace, the demands of e-commerce go far beyond simple interconnection. Competitive demands have made clear the need for banks to stay at the cutting edge of e-commerce technology so that they can provide high levels of service all the time, anywhere, over any communications channel. Banks need e-commerce systems that are integrated with the entire chain of back office and business decision processes for optimum flexibility, responsiveness to changing market requirements, and profitability. Now is the time for advanced e-commerce as no one want to be left behind by its traditional manage all monthly bills including payments to creditors, rates, power and all other invoices. The ability to transfer money between accounts, obtain transaction details and instant access to all financial records is more simple and easier. In fact, nearly all regular banking such as transfers, reconciliations and payments, paying wages and salaries from own office is quite possible through electronic banking. PC connects directly to the bank's computer for simple and convenient access whenever needed.

6.8 Optimization of Branch Networks in Order to Reduce Cost

The main aim of e-banking through the optimization of the branch networks is to tighten internal financial controls, reduce compliance costs, improve operational efficiency and organizational effectiveness, better capital management for significant savings of cash reserves, reduce capital costs from better risk management, improve strategic decision making, enhance perception and reputation among investor and client communities, and provide more flexibility.

With the widespread growth of the internet, customers want to use technology anywhere in the world to access a bank's network. The Internet, as an enabling technology, has made banking products and services available to more customers and eliminated geographic and proprietary systems barriers. With an expanded market, banks also have opportunities to expand or change their product and service offerings. Harnessing enabling technology to provide convenience and quality service through multiple channels at value for money price points is the bank's mission from inception in this electronic age. To this end the banks invested in a scalable architecture that allowed them to ramp up easily and handle the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

rapidly growing volume of customers, apart from reducing costs. To achieve and maintain an edge on its competition, a bank needs an open e-commerce platform that can:

- Integrate new e-commerce applications with existing applications to optimize IT investments and save on reprogramming and management costs
- Provide the power and scalability to handle multiple workloads, shift resources to match changing workloads, handle unpredictable peaks, and grow with the business
- Provide rock-solid security and advanced services availability for transactions all the time, around the world
- Exploit the value of customer and market data by deploying business intelligence (BI) and customer relationship management (CRM) software to help better anticipate, understand and respond to customer wants and needs
- Unify enterprise management chain with an open server platform that integrates purchase and sales processes with information on customers and product offerings for more timely, targeted and personalized customer service
- Integrate future technologies and new ways of doing business with customers

6.8 Banking and Bank Regulations: Potential Challenges for Regulatory Policy

For redistributing capital from areas of excess to areas of scarcity, the most strategic option are the banks and this is the interest of governments of all the countries to watch closely and regulate the financial services in order to control redistribution of capital. Many regulatory reforms have come in to action in the recent years for removing the competitive protections that banks enjoyed for a long time. To survive in the increasing competition from mutual funds, brokerage firms, and insurance companies, banks have to provide complete financial services. Regulatory reforms are expected to allow investment banks to broaden their financial product lines. E-banking has also to accelerate the ongoing process of "financial deepening" i.e. the widening applicability of more formalized financial markets in the economy.

Globalization and increased competition are trends that have shaped the banking industry for decades. The expansion of e-banking contribute to these trends in the same way that previous advancements in telecommunications and data processing did; i.e., by reducing barriers associated with geography and national boundaries. Not only will competition be enhanced by the reduction of geographical barriers, but also by the increased ability of bank customers to search for and locate new suppliers electronically.

There are several ways in which the development of e-banking generates potential challenges for regulatory policy.

1. E-banking and developing technology, more generally are changing the structure and function of financial institutions. The existing regulatory structure has been developed based on traditional lines of demarcation among different types of financial institutions, but these lines of demarcation are becoming less relevant over time.
2. E-banking may raise either new concerns or, more likely, accentuate or lessen concern about existing public policy issues. The most prominent example of a public policy concern accentuated by e-banking has been the issue of privacy.
3. E-banking challenges traditional methods of safety and soundness supervision by changing the nature and scope of existing risks, and possibly by creating new risks.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. Finally, the nature and scope of technological change may require authorities to rebalance their emphases on regulatory rules and industry discretion.

6.9 E-Commerce and the Trends in Banking Industry

With the entry of private banks, the competitive landscape changed significantly over the last few years. There has been one pervasive goal among the banks to increase market share. Banks are employing multiple ways such as increasing the number of branches, installing ATMs, and providing telephone and internet banking. Banks are also adopting new technology and offering new products and services which sometimes take banks beyond their traditional role as pure financial service providers. Banks have established e-shopping malls and portals for making business-to-commerce (B2C) transaction. Banks also are now providing advice on investments and mutual funds.

Financial matters are the most sensitive issue for the consumers all over the world and paid extremely careful attention about personal finances. The reduced level of job security and the need to plan for the future are major concerns over personal debt, saving, retirement planning, and tax planning for the consumers. These concerns can be seen in the trend of customer purchase of investment services like mutual funds, annuities, and trust services.

All over the world, bank's traditional business of taking deposits and lending out the proceeds is on a decline. With the spread of information technology, companies find it cheaper to raise money from capital market than from borrowing from banks and investors have other and often more attractive ways to invest their money than just putting into plain savings accounts offered by banks. These twin pressures compounded by the decline in interest rates have squeezed the net interest margins of the banking industry.

Along with the focus on new products and business opportunities, foreign banks are also developing the global processing centers by taking advantage of the infotech savvy staff and less expensive skilled labor.

7. HOME BANKING IMPLEMENTATION APPROACHES

Home banking services enable to perform banking tasks, pay bills and communicate with the creditors quickly and easily from any computer available which is equipped with internet access. Home Banking allows one to bank on his/her own time.

In the year of 1970s home banking was started via a telephone, which enabled customers to check their account balances, pay bills, transfer funds and general information etc. At that time, with telephone banking, customers use numeric password on telephone to access banking services and to check their account balances etc.

In the year of 1980s home banking was considered via two-way cable TV, which enabled customers to check their account balances, pay bills, transfer funds and general information etc.

In the last decades of the 20th century, computer technology transformed the banking industry. The wide distribution of automated teller machines (ATMs) by the mid-1980s gave customers 24-hour access to cash and account information. On-line banking through the internet and banking through automated phone systems now allow for electronic payment of bills, money transfers, and loan applications without entering a bank branch.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Home banking in historical order, can be broadly classified into four main categories:

- Proprietary bank dial-up services
- Off-the shelf home finance software
- Online services-based banking
- World Wide Web-based banking

7.1 Proprietary Bank Dial-Up Services

The home banking service along with a personal computer and modem enables the customers to transfer funds or pay bills directly from their accounts to the creditors' account and the bank acts as an electronic gateway. Individual customers can subscribe for the dial-up service to maintain electronic checkbook registers and personal budgets, see account balances, transfer funds among accounts, and make electronic payments to other merchants. This type of home banking was very easy to use.

7.2 Off-the Shelf Home Finance Software

This type of service is provided through the software which contributes in cementing relationship between current customers and helping banks to gain new customers. Intuit's Quicken, Microsoft Money, and Bank of America's MECA are some of the popular software which provide home banking services and small business financial services for PC users and allow to organize, understand, and manage personal finances. The information entered once can be seen and analyzed using a set of reports and graphs. This software also helps users to reconcile their bank accounts, and track credit card purchases, investments, cash, and other assets and liabilities.

Online banking services can also be availed through these software as these allow users to download and automatically categorize savings and loan account activity, brokerage activity, and charge account activity, thereby reducing data entry and providing an easily accessible view of their financial assortment.

7.3 Online Services-Based Banking

In this type of home banking service, banks set up their retail branches and subscribe their online services such as Prodigy, Compuserve, and America Online. Although Off-the shelf home finance software allow customers to manage their money, information regarding their financial transactions gets managed two times, once by the customer and once by the banks and the financial banking software cannot reduce this duplication of efforts. Now some home banking financial services systems are emerging that make the bank an electronic gateway and reduce the monthly paper chase of bills and checks.

7.4 World Wide Web-Based Banking

As internet use is growing explosively, World Wide Web-based banking is also gaining popularity with the same pace. This form of banking provides a convenient and superior customer service in a secure electronic environment. Banks are setting up their websites to float their financial products on the internet.

Online banking and internet banking are the two terms which have different meanings in terms of their operational processes. In case of internet banking, no additional software is to be purchased for

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

storing data on customers' computers or no backup of any information is required, or no wait for new versions of software as all transactions occur on a secure server over the internet and banking can be done anywhere and anytime if the customer has a computer and a modem whereas for online banking, it requires a software such as Quicken, Microsoft Money, or AOL which has to be installed onto the computer which limits the customer to banking only from that computer. The first internet bank to provide banking services electronically to internet users was Security First Network Bank (SFNB) and is available on the internet with the website http://www.sfnb.com. This bank offers highest interest rate in America for money market accounts. SFNB is offering joint accounts for multiple parties to access account information from various locations, full personal financial reports, and check imaging for internet banking customers to actually view scanned images of their checks online the day after they clear the bank.

8. OPEN VS. CLOSED SYSTEM

Open systems traditionally refer to a technology scheme that provides customers, external developers, or end-users to access the internal functions of a complex system via "public interfaces." In an open system, contents can be changed easily because of the use of standard technology and components. In simple words, a banking interface developed around the web is an open system that is easy to customize to a bank's changing needs. On the other hand, closed system cannot be changed since everything is proprietary. For example, Quicken cannot be modified unless a new version of this software is distributed by the vendor.

9. MANAGEMENT ISSUES IN ONLINE BANKING

Technology has thrown new challenges in the banking sector and new issues have started cropping up which are going to pose certain problems in the near future. The new entrants in the banking are with computer background. However, over a period of time they would acquire banking experience. Whereas the middle and senior level people have rich banking experience but their computer literacy is at a low level. Therefore, they feel handicapped in this regard since technology has become an indispensable tool in banking. Foreign banks and the new private sector banks have embraced technology right from the inception of their operations and therefore, they have adapted themselves to the changes in the technology easily.

The proliferation of technology-based systems offers tremendous opportunities for banks to communicate with and serve their customers. At the same time, the major challenge facing the banking industry is the optimum use of technology to provide customers with new financial products for satisfying their continually changing financial needs. Banks must deliver high quality products at the customers' convenience with high-tech, high-touch personal and affordable service taking into consideration the five key values: *simplicity, customized service, convenience, quality,* and *price*. In this competitive online banking environment, banks have to be willing to take risk and make strategic decisions about the products and services offered online, and about exploiting the service attributes that build customer retention for profitable customers.

The performance that customers believe is an excellent service, banks can and should deliver, is the true standard for assessing service quality. Therefore, gaining a good understanding of customers' service

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

expectations, as well as variations in those expectations across different customer segments, are essential issues for the management of banks for improving service quality. Consistently delivering superior service quality is much more a matter of meeting and exceeding customers' expectations rather than simply conforming to banks defined specifications. One of the biggest shortcomings of service banks is a failure to understand accurately what is important to customers. Hence for the realization of the full potential of banking financial services following key points have to be considered:

- Attractive financial products and services have to be developed.
- Terminals at an affordable price are required for customers.
- Untapped needs of customers and new market segments have to be explored.
- Service quality on the part of banks has to be established for the customers.

9.1 Differentiation Between Financial Products and Services Strategies

The changing market structure requires the banks and software companies to take the strategic decisions to differentiate their products in the competitive online banking industry and exploit the service attributes that build customer retention for profitable customers.

The proliferation of internet web sites means there may be a substantial advantage for banks able to distinguish their products from those of other banks i.e. to engage in "branding". Doing so requires significant resources for advertising and marketing, a fact that is likely to work to the advantage of large firms. The internet provides a very effective searching device for consumers to choose the "best of breed" producers of specialized services. Intermediaries may play a role in helping users locate the "best" product given their individual preferences for quality, convenience, and price. These factors boost both the pace and scope of consolidation in the banking industry.

There are several significant strategic considerations that should be weighed in determining plans for developing an e-banking service and the type of services that should be offered.

1. Bank management must evaluate the degree to which current and future market demand for e-banking services warrant a change in their e-banking plans. The breakthrough in consumer usage of online banking may depend on developing new and better services rather than reducing the price of standard banking products. It also suggests that low demand for e-banking may be responsible for the "wait and see" posture of some banks toward offering e-banking.
2. Another consideration for banks in determining when, and how deep, to plunge into e-banking is the likely future competitive pressure generated by the development of the Internet. Banks face competition not only from their traditional rivals within the banking industry, but may increasingly find their market share threatened by banks from new, distant locations. In addition, non-bank firms (financial and non-financial) will increasingly contest banks for their most valuable customers.
3. A third strategic consideration in developing internet plans is the question of whether there are "early adopter" advantages. Some analysts point to the high market concentration of e-banking customers in a few large banks as evidence that there will be a few big winners and those laggards will have difficulty catching up. The early-adopter-advantage-view also argue that e-banking will increase the extent to which economies of scale and scope can be realized, and that early adopters will better position themselves to exploit them.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Further, because of the rapid pace and broad scope of technological change in banking and payments, today's early adopter advantage in capturing customers using the current set of e-banking options may suddenly be undermined by the introduction of a new technology.

9.2 Pricing Issues in Online Banking

One of the most crucial areas of decision making for banking is financial product pricing. E-banking is a significant non-interest expense at banks today. There are cases of many banks whose annual costs for e-banking are higher than those for their core systems. Many banks signed their original e-banking and bill-pay contracts several years ago when usage volumes were quite low and many vendors were still incurring high development costs. These contracts included some kind of per-account charge, activity-based pricing e.g. per bill paid, or a combination of the two.

Now, as products have matured and volumes have increased significantly, those same pricing schedules no longer make sense. In fact, many banks have been so successful that the earlier pricing structure is now punitive. Limited use of a cash management product for higher-end business customers can be included, with some limit on the number of customers.

As customer is not interested in paying per month subscription for a service that is already consumed by him at no price, it is much expensive to implement and operate online banking services. However, once a user confronts high connect charges, high subscription fees or both, shows interest in online banking services though customers are very price sensitive. Pricing affects online banking at three levels:

1. **Initial Software Pricing:** Banks have to design strategies through which they can occupy a bigger market share and gain masses of customers. One way of achieving can be through bundling of personal finance products and services in the form of software services with new PCs for the potential customers.
2. **Financial Product Pricing:** The development costs (associated with the design, implementation, and commercialization of a financial product), marketing costs (including costs of launching and maintaining financial products throughout its initial stage), and support costs (including the costs of providing and delivering the product, and maintaining it via back office systems) are the three major costs which have to be balanced.
3. **Usage Pricing:** The volume of transactions in the bank decides this form of pricing. Banks have to offer incentives to attract customers to the service. If the target customers find new products costly, they will resist adopting them.

Pricing is a complex issue that has both long-term implications in terms of cost recovery and profitability, and short-term implications in terms of market penetration. While designing the pricing strategies for the financial products and services, banks must have to consider the above-mentioned issues and make a balance between the costs incurred in providing, delivering, maintaining and promoting their financial products and services.

9.3 Marketing Issues: Attracting Customers and Keeping Customers

While winning customers may be hard, keeping them is even harder. Customers really want quick response, instant information, and solutions to their problems. They want exceptional customer service. No

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

organization can afford to lose customers because of poor service, but many do. Customers remember how they have been treated and spread the news. In today's high tech and demanding consumer market, customer service is mission critical. When customers are pleased, they are likely to spend more on product or service and will call again.

Customer expectations are higher than ever, particularly when it comes to online banking services. Bank operations need to become highly customer-centric in the area of Internet banking to ensure that the services they are delivering are the ones their users will actually use. Customers want access to their accounts anytime, from anywhere, using their preferred device or channel. They expect data that is accurate, up-to-date, and consistent across all channels. They take for granted that they will receive informed and timely support whenever they need it. In short, they want online banking to make managing their accounts and satisfying their financial needs simple and easy. The applications that serve them must be visually appealing, easy to use and learn, and support user personalization that meets individual customer requirements. If an application is difficult to navigate or understand, customers simply would not use it, and may take their business elsewhere.

Additionally, as enterprise customer relationship management evolves, e-banking solutions need to complement and integrate with a banks' customer relationship management strategy. It is no longer acceptable for channels to be independent of one another. A system or solutions must integrate with back-end systems, scale to meet the needs of a growing user population, and contribute to a customer relationship management strategy that will increase customer retention, revenue per customer, and subsequently overall bank revenues.

While meeting demanding customer expectations, banks also need to nurture their own bottom line by building on the profitable relationships they have. They must be able to identify and serve their most profitable customers well, and take advantage of opportunities to offer additional products and services to targeted customers at the most appropriate time. To compete with aggressive competitors, banks and other financial institutions need to be able to:

- Provide services tailored to meet the needs of specific, high-profit market segments, such as businesses. Business customers are often a bank's most profitable customers. The need to attract and retain these customers is critical to a financial institution's healthy bottom line.
- Use the data that they have to identify customer segments and present targeted cross-sell messages when appropriate.
- Consolidate information about a customer so that a customer receives informed, timely, and relevant service regardless of the channel that they use.
- Quickly bring new services to market without disruption to existing services.
- Keep up with emerging technologies while maximizing return on investment.
- Minimize total cost of ownership.

9.4 Managing Financial Supply Chains in Online Banking

The financial supply chain parallels the physical supply chain and represents all transaction activities related to the flow of cash, from the buyer's initial order through reconciliation and payment to the seller. Until recently, the financial supply chain went virtually unnoticed. The amount of time required to process transactions was unthinkably long because the manufacturing supply chain itself was fraught with inefficiencies.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The supply chain financial flow is at a critical threshold of evolution. Current trends in supply chain and financial flow management clearly favor the use of automated payment solutions. Continued expansion in this area offers high potential for reducing significantly purchasing processing costs, accelerating payment and invoice reconciliation, reducing collections costs significantly, creating greater processing efficiencies in the procurement of goods, and enhancing visibility, which means less uncertainty in accounts receivable (A/R) and accounts payable (A/P) and a reduction in working capital needs. As the adoption of new automation solutions for financial flows becomes more widespread, the superior efficiencies gained from electronic payment technologies are becoming more measurable and substantial.

Today the typical financial supply chain remains somewhat fragmented, complex and not integrated with the physical supply chain. Goods move faster than money, and disparate parties are involved. Moreover, even in today's world, the financial supply chain is partially composed of paper-based processes. To stay competitive, "just-in-time" working capital management should be the goal. Financial supply chain solutions enable CFOs and treasury managers to accurately manage their receivables or payables, forecast their company's financial future, and reduce their working capital needs. By optimizing financial supply chains, banks can:

- Reduce their working capital needs by using better inventory control and cash flow management, potentially representing significant annual savings.
- Lower financing rates on required working capital through more effective management of their current asset position.
- Reduce the costs of risk management through greater cash flow predictability.
- Gain early warning into problems with any document in a commercial trade transaction that will likely cause payment to be delayed, then take corrective action to reconcile exceptions.
- Improve customers relations in this money-spinning market, to gain advantage, banks have to follow three strategies:
    - Powerful technology infrastructure, strong information architecture and lucrative online financial products and services have to be developed.
    - Form partnership to link customers, intermediaries, banks, and third-party service providers in the online financial supply chain.
    - Banks have to shift from mass production orientation to mass customization of financial products and services so as to capture the loyalty of the customers by providing simple, convenient, and customer-centered approach for services to the customers.

ABSTRACT

Technological advances and correspondingly the spreading usage of the Internet have significantly changed commerce, and also the concept of money has become more abstract. Customers with the help of the technological advances don't have the necessity of cash money, and consumers/firms tend towards alternative payment methods. At this point, electronic commerce (e-commerce) web sites have started to use block chaining payment methods. In this digital world, new payment technologies have started to spread far and wide thanks to fast improvements in payment technologies, and they offer different options in payment methods. Each electronic payment (e-payment) system has some advantages; however, each of them has some disadvantages as well. The aim of this study is to investigate the e-payment systems which are different from traditional payment methods.

INTRODUCTION

Almost 40 years ago, e-commerce started to come into our lives. As Miva (2011) suggests, e-commerce has allowed many new businesses to enter the online sector and it has still been growing with the advancements in science, new technologies and innovations. There are apparently two time periods for this sector: the first period from the 1960s to 1990s was based on Electronic Data Interchange (EDI)

DOI: 10.4018/978-1-7998-8957-1.ch005

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and the second the period was after 1990s when e-commerce was fostered by the emergence of World-Wide-Web (Yang, 2017).

E-commerce is sure to be one of the most leading services which showed up as a result of the spread of the common Internet users all across the world. With the advancements in technology, the attempts to design mobile devices with a high internet speed as well as mobile technology have made it possible for users to utilize those devices and services like reading e-mails and Web browsing wherever they are and whenever they wish for performing e-commerce transactions.

Throughout centuries, payment systems have undergone a change in a radical way, which include coins, papers and data. The reason why payment systems have continually evolved is that the new technologies included in these systems provide convenience and efficiency at a high speed. The advancements in global electronic payments have changed the humans' point of view. In today's world, many different e-payment systems are being used internationally in a common way and provide security and economic transparency as well as easiness for processes. The users throughout the world provide great benefits vie this payment network. Payments are the basic factors of the economies. With the common adoption of e-payment systems, sale of goods and services has continually been increasing. E-payment has also ruled out the obstacles of immediate liquidity and credit. Today, there are many different e-payment opportunities provided by financial institutions for the customers. As an example, ATM machines, credit cards, debit cards, online banking and mobile banking are among these e-payment systems. E-payment systems are relatively cost-saving over traditional paper-based payments.

In addition to those (Read, 1989) arguing that the use of cash will be removed in the near future, and a non-cash economy is not very far away, there are also approaches suggesting the exact opposite of this argument (Harrop, 1989). Furthermore, many studies in the relevant literature reach a consensus that as economies grow and globalize, physical money will be replaced in shopping by e-payment methods in various forms due to the developments experienced on the internet and e-commerce and the importance of physical money will decline. Accordingly, the more common use of e-payment methods instead of physical money in today's and future's commercial forms is inevitable.

Today, more companies have started performing their company operations through e-commerce. In this way, the purchase of the goods and services produced in any part of the world by consumers depends on the healthy and secure functioning of millions of e-payment processes performed on the internet every day. In this context, the subject of e-payment and e-payment systems, which are among the basic elements of uninterrupted and healthy functioning of the process in the e-commerce-related process, is an area of research coming into the forefront recently with its various aspects.

Each electronic e-payment system has some advantages; however, each of them has some disadvantages as well. The aim of this study is to investigate the e-payment systems which are different from traditional payment methods. In this sense, this paper presents a comprehensive explanation that aims to provide raising awareness regarding the development of e-payment systems. For this purpose, firstly, the concept of e-commerce and secondly, e-payment methods will be addressed. Lastly, the facts regarding e-payments in e-commerce practices will be explained.

E-Commerce in the World

E-commerce has reached to significant levels in all countries, particularly in developed countries. Dues to the increase in internet use and thus, e-commerce, changes that could only be imagined in the past have become a part of daily lives and e-commerce has become a new competition space for businesses.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The main difference between e-commerce and other commercial activities is that customers have increased their purchasing power regardless of their location. E-commerce eliminates limitations for businesses and customers who need to wander markets and make purchases with certain limitations on locations. With online stores operating in the field of e-commerce, customers around the world can do shopping from their homes or businesses, compare prices of products or services they need, and access sellers' information without any limitations on location or time (Ersoy, 2002).

These characteristics made it inevitable for e-commerce to spread around the world. Additionally, commerce, production, marketing and advertisement applications reached a new dimension with e-commerce that makes collaborations and partnerships between businesses operating in different parts of the world easier. It is possible to suggest that there is a correlation between the increase in device penetration due to tablets and smartphones and the increase in the volume of e-commerce. Moreover, through mobile applications such as user interface designs that include current payment systems of e-commerce businesses, there is an increase on mobile device sales. With the increase on mobile penetration, it is expected that a certain population who has not participated in the process yet to be in the digital purchase process. This forces marketing plans to include all customer masses. These marketing plans should target accessing and influencing all users of devices that are connected to the Internet (Criteo, 2015).

According to data on e-commerce in the world from Turkish Industry and Business Association (TÜSİAD, 2017), it is seen that retail e-commerce has reached a trading volume of 1.6 trillion dollars in 2016 and that it is expected this growth rate will continue. Developing countries constituted 38% of e-commerce in 2012 while it's predicted as 63% for 2018. In 2020, it is expected that 64% of the total volume will consist of developing countries. Goldman Sachs, an investment bank, predicts a global trading volume of around 3 trillion dollars in 2020. Figure 1 present's data on e-commerce trading volumes around the world between 2012 and 2020. According to Figure 1, the volume of e-commerce in the world is 632 billion dollars in 2012 while the growth continued and reached 1.6 trillion dollars in 2016. While developing countries constitute 38% in 2012, this ratio increased to 59% and surpassed developed countries.

E-Commerce in Turkey

The concept of online shopping emerged in the early 1990s with the opening of e-commerce businesses. As a result of this process, the trading volume of purchases through e-commerce reached 1 trillion dollars and the interest in the new shopping sector increased. E-commerce has been growing in Turkey as well. However, this growth has not positioned Turkey as a competitor in the international arena. The reason for not being able to reach the e-commerce potential is prejudice by customers due to lack of knowledge on e-commerce and lack of technological, regulational and financial infrastructure required for e-commerce (TÜSİAD, 2014, 58). Additionally, it is observed that all indicators of e-commerce's growth potential such as number of internet users, penetration, smartphone usage, young population, etc. are at competitive level (TÜSİAD, 2017, 41).

Financial sector was the pioneer of e-commerce in Turkey. With a broader scope, the first application of internet marketing understanding was performed by Turkish Republic Central Bank (TCMB) in 1992 with electronic fund transfer between banks. Access to the Internet by large masses such as commercial organizations and households occurred in 1996. In parallel to the developments in the world since 1997, the concept of internet and commerce became popular in Turkey.

BCG has conducted a study to analyze countries' internet densities in three dimensions – providing opportunities (infrastructure development), - expenses (consumers' expenditure on e-commerce and digital advertisement), and participation (frequency of internet use by businesses, government, and consumers). According to this e-density report published in 2016, Turkey is listed after developed countries in the index order but shows a similar performance with developing countries. In the e-density index, it is seen that Turkey has an important potential with its performance in developing countries (TÜSİAD, 2017, 41).

The internet penetration which was 45% in 2012 has grown rapidly and by 2016 it reached to 58% internet penetration with 46.2 million users in Turkey. The estimation for 2020 in Turkey is 62 million internet users with a 76% Internet penetrations. As a result of an increase in internet use, Turkey is the 17th country that has the most internet users in the world with its population of 80 million and 46.2 million internet users and 58% internet penetration. Although when the ratios of Turkey are compared to the 90% penetration rate in developed countries are low, it is similar to developing countries. While the smartphone penetration of 6% in 2010 was below the world average of 9.6%, it reached 65% penetration with the increase in smart phones in the past six years and went above the world average by five points.

Smartphone penetration and the use of mobile internet have become one of the important channels to accelerate e-commerce. As of 2016 in Turkey, about 19% of e-commerce operations have been carried out by smartphones and tablets while it is estimated to reach 49% by 2021. Given the present level of 44% in the world, Turkey is likely to quickly take the lead in mobile commerce with the effect of its young population and higher smartphone penetration.

Results of a study conducted by Deloitte (2017) show that Turkey's position in e-commerce can be determined by comparing to developed and developing countries in order to evaluate the current situation more accurately. Figure 2 represents a comparison of Turkey's e-commerce structure with the e-commerce structure of developed and developing countries. According to Figure 2, the size of market share in retail is obtained by dividing total retail size by online retail size which gave a result of 4.1%. This ratio is 9.8% in developed countries and 4.8% in developing countries. When the ratios of purchases in the last month are evaluated, Turkey has the least purchase ratio in developed and developing countries listed in Table 1.

Source. Deloitte, etid, TÜBİSAD (2017).

When purchases made through mobile devices are examined, it is seen that Turkey has a higher ratio compared to countries such as France, Germany, Poland, Russia, and Brazil. Considering all the data, the fact that market share has not developed yet can be considered as a positive element towards ventures directed at e-commerce. Additionally, the level of purchases made through mobile devices being at the same level as developed countries is important in terms of ventures' e-commerce activities. However, fixed broadband and mobile broadband penetration which reflects Turkey's informatics infrastructure is below the ratios of developed and developing countries. This creates a disadvantage in e-commerce in terms of ventures.

Today, e-commerce activities are mostly done as B2C sales in Turkey. Practices around the world show that sales from business to business constitute a significant portion of e-commerce volume. In Turkey, it is seen that many organizations including big corporates moved transactions between their suppliers and distributors to the internet environment. An increase in the speed is expected over time. Due to e-commerce activities and the increase in gained income, many organizations own their own websites to not lose their customers and to access more customers. Many established brands opened their online stores and internet service providers rent online stores in virtual shopping platforms they

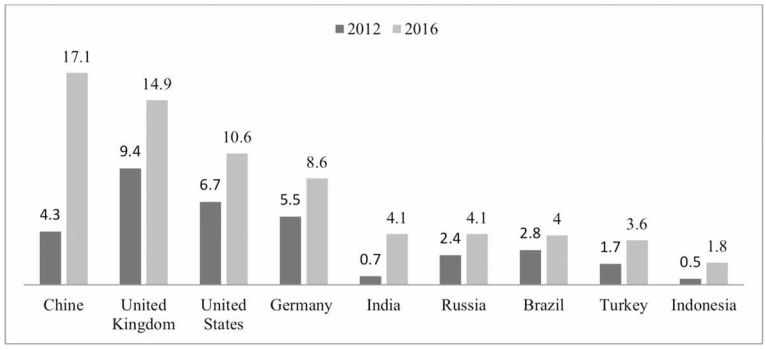
Figure 2. E-Commerce Volume in Turkey (Billions Dollars)
Source. TÜBİSAD (2017)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

created. These developments will result in an increase in the number of companies providing consultant services on e-commerce. Retail portion of the market has grown with an average of 33% annually since 2013 and increased from 7.3 billion TL to 22.9 billion TL in 2017. Only online retail commerce was 14.7 billion TL (Figure 2).

Although there has been a significant growth lately in Turkey, this growth was not sufficient to increase the retail share. In terms of infrastructural processes, Turkey is not different from other developing countries, and it precedes countries such as South Africa, India and China in terms of smartphone use and internet penetration. However, its total share in e-commerce retail is relatively smaller. In the retail e-commerce sector in which China reached the level of 17.1%, England 14.9% and USA 10.5%, Turkey

Figure 3. The Share of EC in Total Trade (2012-2016,%)
Source. TÜSİAD (2017)



has still room for improvement (Figure 3).

As in ‘’the E-Commerce in Turkey’’ prepared by Twentify (2018), Turkey’s expectation for five years between 2018 and 2022 is that this figure will be more than 9.6%, which is the estimated global growth. The expectation for Turkey’s growth rate is 12%, which is more than the global growth rate. According to the survey in question, India is at the top of the list with 19.9% growth expectation.

Although Turkey is not different from other developing countries in terms of infrastructure, and that it precedes countries such as China, India, and South Africa in internet penetration and smartphone use, its share from total retail in e-commerce is relatively low. The share of 1.7% in e-commerce total retail in 2012 increased to 3.5% in 2016. As seen in Figure 3, in the retail e-commerce sector in which China has 17.1%, England 14.9% and USA 10.5%, Turkey has still room for improvement.

Despite its higher growth rate when compared to most of the other countries, it appears that Turkey’s e-commerce total retail and total share of trade volume remain low, which is based on the past and the future expectations for e-commerce in Turkey. The other important issue is that Turkey is a country which aims at the exportation of 500 billion dollars. If this target is achieved by 2023, it means that Turkey’s share of the world exports will be doubled and it will be one of the top 20 exporting countries. However, the current realizations indicate that it will be difficult to achieve this target. But, with the help of the opportunities that e-commerce presents, Turkey can increase its exportation more than before. Reducing the disadvantages caused by distance and even in some cases doing away with them are important advantages of e-commerce (TEPAV, 2014).[1]

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The studies indicate that trade carried out with traditional means between two countries has a negative impact on their trade as the distance between the two countries increases. When the export made by e-commerce is taken into consideration, it is stated that the negative effect of distance on trade volume decreases. For example, the negative effect of the distance on the trade with e-buy is 65% lower than that of traditional exports (Figure 4).

Figure 4. One Percent Increase in Distance Effect on Exports (%)

E-Payment Systems

In modern societies, economic activities are only possible via payments and settlements. Therefore, payment systems could be stated as one of the most crucial and important factors of e-payments (Premchand & Choudhry, 2015). The developments of payment systems and technologies directly affect e-commerce. Globalization and advanced technology implications lead to very significant changes and developments in e-payments as well. In this context, payment methods continue on evolving and varying to meet the changing necessities of users (Qin, 2009).The salient tendencies regarding the e-payments are; faster payments, more mobile payments, new payments, new payment options, improved security implications, Apps and some other integrated payment options (The Future of Payments, 2016).

E-payment is a system that provides tools for payment of services or goods carried on the internet. It provides the ease of transaction processing in e-commerce between consumers and sellers. Using the e-payment systems have many benefits for payers, payees, e-commerce, banks, organizations and governments. These benefits can lead to widespread e-payment systems in the world . An efficient and reliable e-payment system enables faster payouts, better tracking, transparent transactions, reduced time use, cost savings and increased trust between sellers and buyers (Fatonah et.al, 2018). E-commerce is built upon e-payment system and with the increasing volume of e-commerce, e-payment system is becoming more crucial for both businesses and consumers. E-payment systems are used for the completion of e-commerce transactions and can be defined as any payment system facilitating more secure e-commerce transactions between organizations and individuals.

Linck, Pousttchi, and Wiedemann (2006) stated that for businesses that operate electronically, e-payment system**s** are one of the most essential determinants of success. Sales of goods and services have increased significantly with the use of e**-**payment system**s** so that electronic payments have become an increasingly important part of the payment system. E-payment systems have come to replace cash payment systems. However, the emergence of e-commerce has created new financial needs that are not seen within traditional payment systems.

Characteristics of E-Payment Systems There are numbers of concepts characterize the electronic payment systems. These are as follows:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Anonymity

Anonymity means hiding the users' personal identity and the merchant only knows pseudonym of the user. Privacy means protecting the users' information from unauthorized parties (Tsiakis & Sthephanides, 2005). The user's information can be protected by technical activities or by not sharing with third parties. With the characteristics of anonymity and privacy, confidential payment information is not open for any party (Asokan et al., 1997; Neuman & Medvinsky, 1995; Tsiakis & Sthephanides, 2005). The payment system cannot trace the transections if these characteristics are provided. For instance; a customer makes his payment with a credit card; the purchase information is saved to the vendor's and bank's database. This allows other people/parties to find out the amount of the purchase and what the user has bought. Low et al. (1994) proposed a system like this and suggested an anonymous credit card to handle problematic scenarios. Wen (2010) proposed such a protocol to guarantee anonymity with complete security. The users' identity and the purchase information can be anonymized by applying the technical actions mentioned in the related standards. Such as holding the last four digits of the card but not the sensitive data. Securing the users' information can be provided by encrypting the data and registering it to the database that way.

Traceability

Traceability means tracking the flow of money, the sources of the money or the link between the money spent and the customer. (Harris et al., 2011). In e-payment systems, money can be traced using records acquired during payment activities. These records should be kept in a safe and secure system. As we have mentioned before, securing data or information can be ensured by a strong encryption. The information of the credit card used in the payment is kept by the bank or the payment gateway. Traceability is associated with anonymity and privacy of the payment system (Abrazhevich, 2004). Traceability is important for law enforcements for preventing, detecting and prosecuting financial crimes.

Securit

Internet is a wide area network with no centralised control, which means there is no authorization responsible for security. By nature, the infrastructure of the e-commerce and e-payment systems should be secure as a fort, means resistant to attacks over the internet (Neuman & Medvinsky, 1995). Kim et al. (2010) and Hanzaee and Alinejad (2012) shared an opinion that users information can be secured by technical protection, transaction procedure and security. Gupta and Johari (2011) have proposed another approach that using mutual authentication procedure between cardholder and merchant increases the credit card security.

Authorisation Type

Authorization type controls validity of the transaction made (Asokan et al., 1997). Authorization type is a part of security characteristic that can be offline or online. Offline authorization helps users to perform transactions even when the system is not connected to the network, without an authorization server. When we are talking about e-commerce systems, we expect that the payment should be online. But in some occations paper check and payment by conventional cash can also be an option as an example of

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

offline authorization. Within authorisation type there is a model that consists of three parties: customer, merchant and payment authority. Each uses payment order integrity concept. This model includes a merchant agreement to verify payment order (Raghuwanshi et al., 2009).

Trust

Trust, which also can be defined as customer trust, refers to the level of confidence of a customer. This level can vary depending on the security system. The system should guarantee the users' information to be protected, not to be stolen. A high level of trust also ensures that personal information will not be misused, and all parties will act according to the agreement. Reputation and previous experience with the merchant are also another argument of the trust. A good reputation or positive experience will definitely increase trust and vice versa (Egger, 2003). Customer trust can be increased by the two dimensions; trust in the payment system provider and trust in the technology used that the merchant is providing via a web or mobile application.

Reliability

A reliable payment system depends on the infrastructure of e-commerce and the payment system. Uptime of the website is essential for reliability. It is also important for the merchant to provide an easy to use and well secured payment system to the customer. A user would not be happy to have a bad experience such as losing money due to a system crash (Asokan et al., 1997). Also, payment system would be expected to handle some threats, such as attacks from hackers. The payment service should quickly be restored if any failure occurs in the system. That can be done by a high-quality devops and security operations.

Convertibility

Modern banks and payment gateways provide users to make multi-currency payments. This is very important for the e-commerce websites which provide goods and service internationally. Also, customers can choose different payment systems according to their personal needs. It is also possible for each user to use different payment systems at the same time. To Neuman and Medvinsky, (1995), the electronic money in a payment system should be easily converted regarding the needs of the customer or the system that the merchant has. Conversion should be made without any limits. As Abrazhevich (2004) suggests, the multi-currency characteristic is considered as part of the convertibility.

Usability

Modern e-commerce systems provide users to save their payment information for their later purchases. This allows customers to make their payments with a free of effort as Davis (1989) suggested. According to Neuman and Medvinsky (1995), users should not be disturbed to provide payment information in each purchase. Payment process should be carried out automatically. That means the payment system should be user-friendly and easy to use. If not, the customers will probably not prefer to use it once more.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Interoperability

Interoperability relies on inter-development of the payment system. It is also important to work together with an efficient integration between the different solutions. An interoperable system could get a customer base more quickly, which is required for the development in the future with a higher adoption rate. Because the users are already familiar with that kind of payment systems they make payments without any hesitation.

Scalability

For an e-commerce website, the primary aim is to increase their customer number. That means the payment infrastructure must also be able to answer the increasing number of new customers. Researches show that slow payment systems make the customers cancel the purchase and leave the website. Fort hat reason, payment systems should work successfully without having any problems. It is also important to serve with high uptime and a good quality of service, even when there are huge numbers of users (Medvinsky & Neuman, 1993; Neuman & Medvinsky, 1995).

Efficiency

Efficiency is important for SMBs due to the characteristic of their payment model. Generally, SMBs need for micropayments and small payments. According to Hauser et al. (1996), a payment system must be able to process small payments and micropayments without any performance problems and high costs.

Applicability

The payment system should be applicable to the e-commerce system. The e-commerce system can be a free or commercial solution. Regardless of the technology used for the e-commerce solution, the payment system should be integrated easily and work properly. Applicability is also important for the customers. They most probably will prefer making payments via debit and credit cards. That means, the payment system should have a very high level of applicability for that payment systems.

Assessment of E-Payment Systems

There are four aspects to consider in assessing e-payment systems that are; technological, economic, social, and regulatory.[2] In assessing the technological aspect of a payment system, it would be accurate to consider efficiency and security of transactions, the system's expandability, and compatibility with other payment methods as well as user-friendliness. There are requirements to fulfill for companies to ensure security. These requirements include privacy, authenticity, integrity, and non-repudiation. Privacy requirement is related to anonymity protection of customers during transactions and the prevention of unauthorized parties from accessing customer information. Authenticity refers to verification of identities involved in transactions in order to prevent unauthorized access to information. Integrity requirement deals with prevention of data tampering during transactions while non-repudiation requirement is to prevent denial of commitments made during transactions. Thus, it is important to record and verify details of transactions. Economical feasibility is an important factor in terms of designing, building,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

maintaining e-payment systems. Economical feasibility depends on widespread use by customers. The Economic needs of e-payment systems include transaction costs, atomic exchange, accessibility, value mobility, and financial risk. Direct and indirect costs involved in a transaction as well as fixed costs should be considered in e-payment systems. Additionally, whether a system is widely accessible or not is another consideration.

In addition to economical and technical aspects, electronic payment systems should also consider the requirements of social aspects which include anonymity, user-friendliness, mobility, and regulations. An e-payment system should ensure its customers of protection of anonymity which is a critical factor. Also, user friendly and mobile systems would be more likely to be preferred by customers. Customers prefer systems that are easy to use and that can be used from anywhere. Regarding regulations, e-payment systems should ensure to follow government regulations of the country where e-commerce activities take place. These regulations include but are not limited to digital signatures, customs and taxation, international agreements, etc.

Categories of E-Payment System E-payment is and sub-category of an e-commerce transaction which encompasses e-payment for buying and selling goods or services through the Internet. Although there are many other types of e-payment options are available[3], we generally assume that e-payments are online transactions on the Internet (Premchand & Choudry, 2015). Payments methods according to the systems mentioned are given in Table 2.

Table 2. Payment Methods[4]

Online Payment	The payment method is initiated by a user who has an access to the Internet.
Offline payment	The offline payment method is a method which mail/phone order or sales points or any other offline methods are used.
Mobile Payment	The mobile payment method is method which can be done via using the customer's cell phone or any other device's data function.

Source. İGEME (2009)

Some of these systems are discussed in the following section.[5] Although the related literature which is used in e-commerce payment methods is quite similar, there are different classificiations. Please see the other classifications in Premchand and Choudhry (2015), TÜSİAD (2014), Hidayanto et al. (2015), Yang (2017), Turban et al. (2018). The other global e-payment options are Cash-On-Delivery, Electronic Cheque, Credit Cards, Debit Card, Virtual Card, Mobile Payment, Electronic wallets and cryptocurrency.[6] The mentioned payment methods will be explained here:

Cash-On-Delivery

Cash-on-delivery system, which gives clients the opportunity to make payment at the door to the courier company, both supports e-trade and promotes online-sales by adopting conventional payment habits to technology. Cash-on-delivery is a payment system that does not need any integration. Cash-on-delivery can be used in payment by in cash or by credit card. Its advantage is that you do not have to reveal your

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

financial information like debit card, credit card or account information to the seller and payment is occurred upon delivery. Another advantage is that it rules out the dependency on credit or other payment cards.

Cash-on-delivery, which is one of the alternative payment systems that e-trade clients use, comes forward as an application for the undertakings to differentiate themselves from the others in competition. Accordingly, e-trade undertakings create an important opportunity by providing payment options in cash or by credit card for the clients who still continue their old consumption habits.

Electronic Cheque

Electronic cheque (e-cheque) is a payment system for e-commerce websites to accept payments by cheques. E-cheques have been designed for clients who do not want to make payment in cash as a virtual equivalent of cheques used in real life. There is no difference between e-cheques and paper cheques (Oney et al., p. 397). As different from the paper cheques, a digital signature is used on the e-cheques. A Digital signature is an encryption system on a network, which has been created for security purposes in transactions that are not done face to face. In the e-cheque system, payments are made by entering only necessary bank account data to the e-commerce website. In other words, the user makes the payment by making out a cheque to the e-trade web site. Although it is an easy system, its use is not as widespread as the other mechanisms. For its more extensive use, it should be accepted by the financial sector.

In e-cheque system, there is a promise to buy a good with declaring a reason. Since the amount is fixed, there will be no transfer of any extra payment other than the fixed amount and if it is understood that the service will not be provided or badly done there is right to withdraw without making any payment. Therefore, it is a secure way for payment in e-commerce.

Credit Cards

Credit card systems are preferred more often than other e-commerce payment tools because they provide users several financial advantages such as insurance, bonuses, installment and security. While credit cards provide added value to customers, they incentivize businesses to meet the standards and reduce transaction costs through automated accounting.[7]

In addition to having a legal infrastructure that is standardized in the world and high security, credit cards are easy to use (Khan et al., 2017). The customer would only need to enter the credit card number and the expiration data on the website of the merchant. In order to improve security systems, several practices such as using card verification number (CVN) are implemented in online credit card payments. The CVN system helps identify fraud by comparing the CVN number with the information of the cardholder.[8]

When a customer makes a purchase with a credit card, the card issuer bank makes the payment on behalf of the customer which would allow the customer to have a time frame in which he can make the payment for the credit card. The actors involved in a credit card system are as follows:

Card holder – Customer **Merchant** – product seller who accepts credit card payments **Card issuer bank** – card holder's bank **Acquirer bank** – merchant's bank **Card brand** – such as Visa or Mastercard

Some of the companies that export and issue license of use credit card and card systems worldwide include Mastercard, Visa, American Express, Discover and JCB.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Debit Card

Debit card is also known as a bank card (Oney, 2017, p. 397) and it's a payment tool used in e-commerce and several transactions. It is one of the most popular payment methods without using cash (Kim et al., 2010). As this card does not provide a credit option for cardholders, it's not considered as a credit card. Debit card, in this context, is a card without credit card characteristics that allows the owner to withdraw and deposit money to checkings account. Debit card holders can withdraw money from ATMs of the bank they have an account with for 24/7 and make purchases through POS machines. During shopping, the amount of purchase is withdrawn from the cardholder's checking account and transferred to the merchant's bank account. Bank cards can be used as credit cards in payments made online. However, as they are not credit cards, the payment takes place as a money transfer from the user's checking account to the merchant's bank account. In comparison to credit cards, debit card costs incurred are lower which allows them to be used for micropayments. Additionally, the level of security of debit cards is higher than credit cards as the required identification processes demanded by banks are more rigorous (Khan et al., 2017). There are two kinds of debit cards that are; online and offline debit cards.

Virtual Card

Virtual card, as the name suggests, is a virtual product to reduce the risks of online shopping. This card that does not have a physical form but has digital information of the card user's bank account. Virtual card has a different card number and pin number from the physical card (Çakırer, 2013, p. 153).

Virtual card practices are provided by banks in Turkey. Banks issue virtual card or virtual credit cards with multiple functions to provide a safe environment for commercial activities, and to incentivize e-commerce customers. The most important aspect of virtual credit cards is that it is a card type that can onlu be used for online shopping within the limits the card owner determines via internet banking and that it can't be used in pos devices in stores. These cards are not printed as other cards and transactions are made only through the number determined by the bank (Zerenler, 2013, p. 103).

Mobile Payment

Online payments made through cell phones in e-commerce are called mobile payments. This method of payment is easy to use and in this method a payment request is sent to service provider via text instead of credit card use or cash payments. Prior to each online purchase, the mobile user authorizes the payment and the purchase amount is reflected on the user's phone bill. Consumers who have pre-paid phones make their payments through their balance on their phone.

There are several methods for using mobile payment services. While most of these methods use advanced technologies, some methods are considered as processes used through current technologies. The "new field communication" (NFC) method, one of the newer mobile payment methods, is designed with a focus on mobile payment solely. Several other mobile payment methods are performed through mobile networks and use traditional communication models such as SMS.

This method which is being used for the past few years in online purchases provides a possibility for payments to be made from anywhere which is a reason for being considered as advantageous and preferred. Also, mobile payment can not only be used in online shopping but also in stores. Mobile payment systems are safe payment systems as they make payments possible by using customers' cell phone num-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

bers without sharing any card information or making cash payments. The concept of m-money emerged with mobile payment and it aims to replace cash for small transactions and removes disadvantages for cash use such as getting stolen or lost, or storing, etc.

Although there have been developments in current mobile payments during the past few years, payments are supported with SMS or e-mail with the 3D-secure system in terms of security. Along with payment models that center around banks in which mobile network service servers have the responsibility for secure communication, there are payment models that mobile network servers take on a bigger role. With the number increase in smartphone owners, the number of applications related to mobile payment services continue to increase. The number of mobile payment system users continue to increase worldwide. A study conducted by Gartner company showed that the number of mobile payment system users worldwide would be 200 million by 2012. This number increased to 245 million in the year 2013 and is expected to increase to 450 million by 2017 (McDermott, 2015, p. 6-7).

Mobile payments today are mostly used in the continents of Asia and Africa. Mobile applications that started with money transfer and mobile trade are being improved with applications that include invoices and pre-paid bank cards. Cell phones are not only communication devices anymore but also a small computer that's carried all the time. Today, all banking and payment transactions can be performed via cell phones. (Please see the other explanations of mobile payments; Bezhovski (2016); Kim, Mirsobit, and Lee (2010); Cabanillas and Rubio (2017).

Electronic Wallets

Electronic wallets are also referred to as digital wallets and provide the opportunity to store more than one credit cards, bank cards, and bank account numbers in a secure environment. Electronic wallets contain bank card numbers, electronic money, the owner's identity and communication information similar to an actual wallet. This removes the need to enter account information in every payment. Thus, entering card information to digital wallets one time and choosing the option of paying with e-wallet is sufficient rather than entering card information in every online purchase. Once the electronic wallet profile is created and saved, payments are made faster.

Electronic wallets are convenient for those who prefer to pay with a credit card Electronic wallets that make e-commerce faster and more practical are preferred mostly by consumers at the young age group. The number of e-wallet users increase in direct proportion with the number of e-commerce users which indicates that the digital wallet use will become even more frequent in the future. Amazon Pay, Google Pay, Apple Pay, Ali Pay, ByoWallet are among e-wallet providers that are mostly seen in international e-commerce activities.

Cryptocurrency

Cryptocurrency is a type of currency that draws on the cryptography science (Gandal & Halaburda, 2014). Cryptography is used in controling the processes of securing purchasing, selling, and payment activities as well as creating new currencies. Cryptocurrency (digital money) can be used both as an investment tool and as an alternative payment method which creates new opportunities for e-commerce companies. With its decentralized structure, it has characteristics such as being independent, low-cost, and fast transfer which attract more and more attention from users. Therefore, cryptocurrency is becoming a popular currency and a payment method. However, it is frequently mentioned that cryptocurrencies

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

are still in the early adaptation phase which is why waiting for the industry to mature and technology to improve are recommended often. Despite different views, the number of companies accepting cryptocurrency in online payments is increasing every day.[9] Thus, the likelihood of cryptocurrency being a common payment method in e-commerce is very high.

Cryptocurrency was first introduced in 2009 through bitcoin which is positioned on a non-central architecture and it became a popular payment method in commerce with over 2000 types. Cryptocurrency is a kind of virtual money. The database algorythms that underlie the concept of cyrptocurrency and that are very different from traditional methods have been accepted. Banking sector has already started working on transitioning to this data base system. Commerce of a product occurs through transferring money from a digital wallet to another through electronic codes by eliminating mediators such as visa/mastercard and related commissions or costs. Within the frame of all these developments, the very first example of cryptocurrency application in the world is Bitcoin[4] and it's the most known cryptocurrency in the world.

The blockchain technology that provides high security due to cryptography method paved the way for cryptobased payment and money transfer as[10] well. Additionally, as cryptocurrency are not dependent on a central authority or an intermediary, it allows shopping to occur between the seller and the buyer only and thus, a faster payment. Within this context, unlike the slow speed of current payment methods and high costs, crypto payment methods provide a faster and less expensive way[11] for global payment activities. Despite the high potential and advantages it has, there are some negative aspects of cryptocurrency such as high price volatility, requirement of additional installment in order to accept crypto payments, and transactions in cryptocurrency being irreversible. Thus, it is important to be careful when making transactions and not saving personal information. Also, it should be known that legal infrastructure is not completed yet. Bitcoin constitutes 54% of the 220 billion dollar-cryptocurrency market.

In 110 countries out of 251, Bitcoin purchase/sales is free.[12] In the case of Bitcoin, the total currency units that can be in the market are limited to 21 million units (Ron & Shamir, 2013). From this aspect, it can be used in more than hundred countries as a payment method. Also, there are crypto payment gateways that allow the use, collection, and saving of several cryptocurrencies such as CoinPayments, PayCoiner. BitPAy, PumaPay, and Coingate.

Van Alstyne (2014) stated that the technical aspects of Bitcoin include that it can be used by its owner and one-time, the transaction fees are almost zero, that it is accepted as a payment method due to its success in identifying fraud with its open-access activity history. Additionally, the first day it was open by an online shopping portal, 125.000 USD-worth of transactions made. Churilov (2015) discusses the advantages and disadvantages of Bitcoin as a payment method, and its validity and taxation in international legal corporates. According to Churilov, Bitcoin is a currency unit that is immature and has high volatility. Thus, he warned companies using Bitcoin to be careful due to security problems and uncertainty in its legal status. Angel ve McCabe (2015) approached this from an ethical perspective and discussed the imbalance of power between the payer and the receiver. Within this context, they examined if reinforcement of Bitcoin as a payment method would be considered as misuse ethically and concluded that a potential misuse would not stem from the nature of Bitcoin.

Online Payment Gateway Model

Today's e-commerce world is less challenging then before. In the previous times of e-commerce, merchants have had to provide virtual POS services from each local banks of the base country. Now, there

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

is a new and –relatively- better solution: Online Payment Gateways.This model is a service that sends credit card information from a website to credit card payment network to be processed and then sending transaction details and responses back to the website. If credit card payments are accepted online device, businesses need a payment network channel. This can be considered as the safe technology bridging for the customer and the business. In today's world where online shopping is popular, the use of online payments provides several advantages to both merchants and clients (customers). Online transactions are performed through a payment gateway during the process. Practically, payment gateways serve as a link between financial organizations and merchants' website. There are several factors involved in online payment processes during selling or purchasing products. Electronic Payment Gateway is fundamental for online transactions and they ensure reliable and safe exchange. An E-Commerce Payment Gateway is a part of infrastructure guaranteeing exchanges happen without any problems and electronic system security is maintained. A Payment Gateway is a point of access to national banking systems. Every online exchange takes place through a Payment Gateway which routes and confirms payment details securely between related banks and parties. Payment Gateway serves as an "encoded/encrypted" channel that sends transaction details from customers' online devices to banks for the purposes of authentication and countersignature. Once the approval is obtained, the Payment Gateway sends the data back to the merchant, completes the "order", and provides information of the payment process (Khan et al., 2017; Masihuddin et al., 2017). Stripe, Amazon Payments, Braintree, Authorize.Net, WePay, BlueSnap, Skrill, PayU, Dwolla, PaySimple, Paddle, PayPal, Payoneer, Yandex Checkout are among popular International Payment Gateways.[13]

FACTS AND TRENDS

Non-Cash Transaction

While the purchase of goods and services with cash payment is a traditional payment system reaching from past to present, e-payment systems have become a commonly used and preferred method instead of cash payment today. As a result of the evolvement of economies and commerce into a non-cash structure, e-payment systems instead of physical money come to the forefront in the commerce forms of the future. With the use of the internet, the system of payments has varied starting from the end of 1990s and although there was only one option as credit card before 1990, many payment systems are used today, and many payment systems are in the development process.

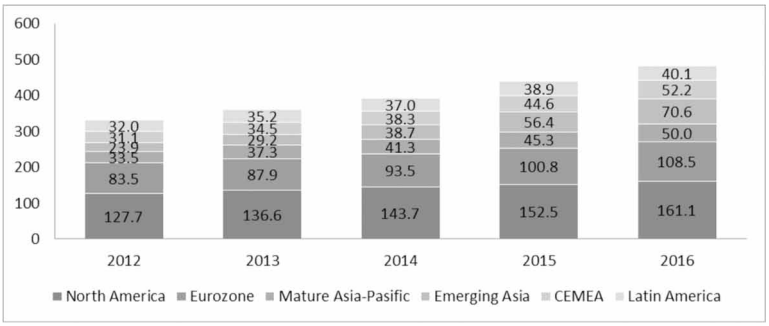
Within the context of our subject, the facts and trends regarding the usage density of domestic and foreign e-payment tools and systems are among the important issues to take into consideration for estimating the use of non-cash e-payment tools that are alternative to both cash and each other, healthy investment in terms of central banks, which are the determinants of monetary policies, as well as consumers and companies constituting the production and consumption side of goods and services in addition to making appropriate preferences.

According to World Payment Report (2018), during 2015-2016 global non-cash transaction volumes grew at 10.1% to reach 482.6 billion. Two regions fueled this growth: Emerging Asia (with 25.2% growth) and CEMEA(17.1%). Overall, the developing markets of Emercing Asia, CEMEA and Latin America recorded accelerated growth rate of 16.5% in 2016, driven by financial inclusion efforts and the adoption of mobile payments. It needs to be noted that overall volume of non-cash transactions grew significantly

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

as shown below. All industry stakeholders will have to adopt e-payments and mobile payments channels as these channels are continuously driving growth of non-cash transactions. Following figure shows the Global number of non-cash transactions between 2012 and 2016 (Figure 5). As per World Payments Report 2018, by 2021, there will be a major shift in payments industry - banks may not be at the centre of payment governance. Non-bank organizations and retailers will be encouraged more to participate in the payment chain. Total number of non-cash transactions are predicted to touch 876 billion by 2021.

Figure 5. Non-Cash Transaction By Region (Billions Dollars)
Source. World Payments Report (2018), CEMEA (Cenral Europe, Middle East, Africa)



In the North America and Europe, payments market is dominating, however, in the following years it is possible for this situation to change since developing markets share can be half of total non-cash transactions by 2021. Key areas where changes are estimated to go on will undergo some fragmentations and consolidations. Consumer protection will be provided with more anti-fraud measures. Some data policies could be applied, and it could affect this process. Such new currencies as reward points, mobile air time and digital currencies (bitcoin) can make a change in the way in which the payments are being made. There can be used some identification methods in other industries to protect the consumers. These methods can affect banks, payment processors and retailers.

The realization of noncash payments in Turkey show parallelism to developments in the world. The most preferred payment method in 2015 and 2017 was credit card with 61% and 68%, respectively. The decrease in cash payments and the increase in using credit card as payment method show parallelism. While the use of cash payment method was 35% in 2015, it decreased to 27% in 2017. Additionally, considering the fact that there are over 20 million consumers without a bank account or credit cards, and that the percentage of individuals considering getting a credit card increased from 11% in 2015 to 37% in 2017, it can be predicted that noncash payments will increase in economic activities and e-commerce. For details on the advantages and disadvantages of transitioning to non-cash economy in Turkey, you can refer to Elgin, Erzan & Kuzubas (2013) and BKM (2017). Within this context, compatibility should be established related to systems with credit card and other methods of payment in Europe and Asia as the first step in transitioning to a noncash society.[14]

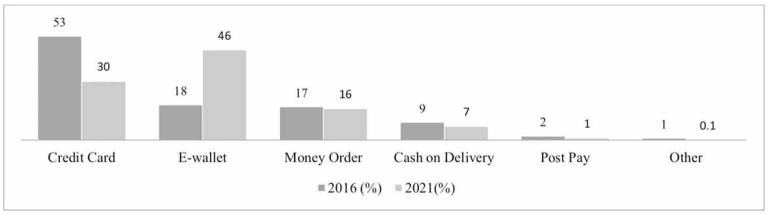
E-Payments

As economies grow and globalize, the need for non-cash payment tools has increased. For example, while paper-based payment tools such as checks were initially used, the difficulties brought by the incredible increase in the number and amount of transactions in the international payments and the opportunities offered by the technology in these areas have expanded the use of e-payment tools. In parallel with the aforementioned developments, national and international payment systems and tools alternative to each other have been developed in many countries and are still being developed. In this context, the use of alternative e-payment methods, which both replace cash and increase its efficiency by relieving the use of e-commerce, has become widespread in almost every country.

In the context of national and international e-commerce practices, how to use the e-payment technologies and systems as well as which payment tools will be used is the key of performing online purchase and payment. E-payment systems are increasingly used throughout the world in parallel with the developments emerging in the fields of commerce and technology.

The expectations with regard to the development in international e-payment methods for e-commerce could be seen in Figure 6. There are two elements coming forward in Figure 6. First, the expectation for the rise of the share of e-wallet usage, which is one of the outstanding elements of digitalism, in the international e-payment methods from 18% to 46% by 2021; secondly, the expectation for the fall of the share of credit card, bonus card and pre-pay cards usage from 53% to 30% in the international e-payment methods. Consequently, although the payment method has been changed, the goods which are being paid have not changed. Accordingly, the share of international e-payment methods by cards and e-wallet is expected to rise from 71% to 76% by 2021. It is because that the infrastructure of these payments is very appropriate for e-commerce. In this sense, the share of payment by cards is expected to be higher in the future.

Figure 6. E-Payment Methods (%)
Source. Global Payments Report (2017).



In Turkey, 85% of payments are made by cards. It is very remarkable, as the share of payments made by card in the world is 71% today. Therefore, the card ownership rate is quite high in Turkey and the rise in the use of e-wallet could be expected as a result of change in composition or other payment tools special to Turkey might come forward. The facts regarding e-payment in Turkey are shown in Figure 7. Since credit card is mainly preferred for purchasing in e-commerce in Turkey, the development of the e-payment systems that will provide secure shopping and easy payment is very important for the growth of the sector.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 7. E-Payment Methods in Turkey (%)
Source. Global Payments Report (2017).

In the near future, the retail sector and thus e-commerce will have to undergo a significant transformation in the countries where alternative e-payment systems cannot be commonly used today but seen as an important opportunity. In this sense, it will be inevitable for socities to direct to alternative e-payment methods rather than the use of cash.

If the companies, which want to carry out e-commerce activities in different places of the world, have infrastructure supporting as many payment methods as possible, they will gain many advantages and in this way, they will optimize their online incomes thanks to the ability of making the transaction process as easy as possible for their customers. Figure 8 given below details the e-payment systems used in e-commerce according to the geographical regions in the world. Although many alternative e-payment methods frequently mentioned in the recent period show a great increase in every period compared to the previous period, their shares in the total composition are extremely low.

Figure 8. Preferred E-Payment Methods for E-Commerce (2018,%)

SOLUTIONS AND RECOMMENDATIONS

It is not possible to state that e-payment systems are the same in all continents or countries. Some of the important reasons for this include the demographic characteristics, the degree of financial literacy, the infrastructure provided by the financial system, the advantages and disadvantages of e-payments, the level of income of consumers and the extensity of e-commerce use. Therefore, it is a very natural situation that the e-payment methods preferred by consumers are different. In this context, having various e-payment options suitable for customers is crucial for companies in terms of not being devoid of important operations. Since the growth in global e-commerce significantly results from cross-border e-commerce, every company in e-commerce should aim at certain alternative payment systems and tools, which are popular in different countries or regions, for alternative e-payments. As e-commerce becomes widespread and develops, even the solutions that are seen as optimal today may not be permanent since e-payments will vary. Not integrating appropriate e-payment systems will cause companies to encounter problems in every field. The way of turning the problem into an advantage is to provide e-payment methods appropriate for customers.

FUTURE RESEARCH DIRECTIONS

With the rise of Industry 4.0, the concepts such as robots, artificial intelligence and artificial neural networks have started to be increasingly used in the production and sales process of goods and services. These developments will inevitably affect all sectors. The e-commerce sector will have the opportunity of using the big data constantly increasing in the digitalized world more effectively by benefitting from the artificial intelligence. Thanks to the artificial intelligence, e-commerce websites will be able to offer products special to the users who do shopping, make a voice call, their payment systems will be simpler and more user-friendly and there will be a more refined functioning logistically. The semantic web technologies of the past will give place to the web applications having artificial intelligence and with the use of developments such as artificial intelligence in e-commerce, significant returns will be achieved in terms of efficiency. This means that in the e-commerce of the future, more intelligent and self-learning shopping systems will be active thanks to machine learning. As a result, the involvement of Industry 4.0 and artificial intelligence, one of the basic elements of it, in e-commerce activities can affect many technological, economic and legal factors, it is important to conduct more studies on the field.

CONCLUSION

With the increasing interest in e-commerce, companies have started to look for alternative e-payment systems for themselves. In addition to this need, the widespread use of smart devices and Internet has diversified e-payment systems and extended them to a wide range and the use of alternative e-payment systems has become widespread in every country. The widespread of e-payment systems has increasingly caused economies to evolve into a non-cash structure. Considering the expectation that global e-commerce volume will reach 4 trillion dollars in 2020, the changes that will occur in e-payment systems, which are the most important elements for the healthy functioning of millions of online payment transactions to be made today and in the future, will affect the development of e-commerce directly. While having national

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and international different payment alternatives enables companies to reach more consumers from different sectors/geographies, it will also increase the chance of being preferred by the potential customers due to payment diversity. In this context, the relation between e-commerce companies and consumers enhances thanks to offering different payment alternatives. Today, many different e-payment methods such as payment with card, e-wallet, mobile payment, cryptocurrency etc. are offered by companies when purchase-sale is performed with e-commerce. Consumers' preference regarding alternative payment systems inland and abroad varies depending on many factors such as income level, demographic characteristics and financial literacy. While credit cards and debit cards are commonly used among the alternative e-payment tools, the use of e-wallet has outdistanced the use of credit card or they compete head to head in many countries. Mobile payments, which have a very high potential, have shown a significant progress, however, it is not possible for mobile devices to offer an experience similar to the one that consumers experience on WEB. The use of cryptocurrencies as a payment method is not possible today compared to mobile payments. Consequently, considering that the developing technology can change many things in the course of time, the determination of payment preferences is very important for the competitiveness of companies.

KEY TERMS AND DEFINITIONS

Electronic Commerce: E-commerce is a concept covering the purchase and sales of any good or service by using information technologies, electronic communication channels and other relevant technologies through cyber space. According to a different definition, e-commerce refers to the traditional

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

trade which is performed on a web environment or mobile. There is also another definition stating that e-commerce includes purchases-sales whose payment transaction is made through the internet. Contrary to the general view, e-commerce is not only performed through the internet, but also other wide networks as specified above with the term "cyber space".

Electronic Payment System: E-payment system is the means of making payment and/or transaction for goods and services on an e-commerce website or electronic environment without any need to use cash or check. E-payment system is also known as online payment system. It has many forms such as credit card, virtual card, mail order, e-wallet, mobile payment, cryptocurrency, etc.

Payment Gateway: Payment gateway is a system that facilitates payments in a strict sense. In a broad sense, it is a service that securely encypts confidential information regarding credit card, debit card and other electronic payment methods of users giving online order on e-commerce systems, conveys them to the e-commerce manager and to the bank or intermediary institutions from the e-commerce manager in compliance with the related standards (PCI DSS) and enables the processing of online transactions real-timely.

Chapter 6
Infrastructural Drivers of Online Shopping: An International Perspective

Syed Akhter
Marquette University, Milwaukee, WI, USA

ABSTRACT

While online shopping expenditures have been increasing in both developed and developing economies, they still account for a small share of total retail sales. Significant differences also exist across countries in the amount of money consumers spend on a per capita basis on online purchases. The authors utilize the conceptual foundations of infrastructural framework to examine the effects of infrastructural drivers on online shopping expenditures in 43 countries. Findings show that per capita telecommunications investments and per capita gross national income are significantly associated with per capita online shopping expenditures. Privacy protection, Internet penetration, and credit card penetration were not significant.

1. INTRODUCTION

The Internet has significantly transformed consumers' shopping experiences by expediting product search, facilitating price comparisons, and reducing transaction costs. Taking advantage of these conveniences, consumers have shifted some of their purchases to the online channel. However, while consumers' preference for the online channel has resulted in increasing online sales, data show that online sales across countries still account for a small share of total retail sales. In the U.S., for example, after more than four decades of the commercial launch of the Internet, e-commerce sales were about 5.8% of total retail sales in 2013, increasing from 5.2% in 2012 (U.S. Census, 2014). And in China, where the compound annual growth rate from 2003 to 2011 was 120%, the highest growth rate in the world, the share of e-commerce sales to total retail sales was only between 5 to 6 percent (McKinsey, 2013).

To explain online shopping activities, existing research has mostly focused on demographic characteristics (Akhter, 2003; Chang and Samuel, 2004) and attitudinal and motivational determinants such as beliefs, risk averseness, norms, intentions, and perceived value (Brashear et al., 2009; George, 2004;

DOI: 10.4018/978-1-7998-8957-1.ch006

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Lim, 2015). In contrast to the large body of research on demographic and psychological determinants, the literature on infrastructural drivers of online shopping is still in the early phase of development (Travica, 2002; Sheth and Sharma, 2005; Alqahtani et al., 2012). A review of the literature also shows a dearth of empirical studies on the effects of infrastructural drivers on online shopping expenditures across countries.

This study attempts to fill the above-mentioned gaps and contribute to the literature in three significant ways. First, it builds on the infrastructural frameworks developed in existing studies to formulate the hypotheses. Second, it tests the effects of three key infrastructural drivers (telecommunications, financial, and regulatory) on online shopping expenditures across countries. Third, it draws theoretical and strategic implications of the findings, adds to the existing knowledge on infrastructural drivers and online shopping, and guides strategic decision making.

To accomplish the research goals, the rest of the paper is organized into the following four sections. In Section 2, we discuss the theoretical frameworks and, in Section 3, we present the hypotheses. In Section 4, we discuss issues related to the sample and variables and present the results, and, in Section 5, we draw theoretical and managerial implications, discuss the limitations of the study, and suggest questions for future research.

2. THEORETICAL FRAMEWORKS

Existing research has delineated the linkages between infrastructural conditions and online transactions. Travica (2002), for example, conducted a field investigation to determine how infrastructural factors affect the diffusion of e-commerce. Interview and observation data showed that economic, telecommunications, and cultural factors favorably affect the potential for e-commerce. Simon (2004) also identified communication infrastructure and legal and societal factors such as privacy protection as critical success factors for facilitating electronic commerce in developing countries. Das et al. (2014) explored the effects of economic, legal/regulatory, and technological factors on music piracy and found that the primary factors that affect online piracy in a country are its economic status and regulatory status.

Sheth and Sharma (2005) classified countries based on their infrastructural development and proposed that the level of development in telecommunications and legislative bodies would affect e-marketing activities as well as consumer behavior. And Lawrence and Tar (2010) noted that underdeveloped states of telecommunications infrastructure, credit systems, and income would act as barriers to e-commerce activities in developing countries. In a recent report, the Euromonitor also emphasized the importance of developing adequate telecommunications and financial infrastructures to promote online shopping (Euromonitor International, 2012).

In addition to the roles of telecommunications and financial infrastructures, existing research provides meaningful insights into the role of privacy in influencing online shopping. A key conclusion from the current body of research is that while consumers appreciate the convenience of online shopping they remain apprehensive about the threat to privacy it poses. Privacy concern among consumers has been shown to be a significant determinant of online shopping and research shows that it negatively affects online purchases (Dubelaar et al., 2003; Zorotheos and Kafeza, 2009). What, however, is important to note about the privacy literature is that much of the scholarly attention has been applied to understanding the antecedents and consequences of privacy concern and not to examining the effects of the regulatory infrastructure that protects privacy.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Wirtz et al. (2007, p. 344) have emphasized the importance of examining the differences in the privacy approaches and practices of businesses and governments to "protect consumer privacy" in the different geographical regions of the world. Erbschloe (2001) also identified cross-country differences in privacy regulations as one of the key trends impacting the use of the Internet. Existing literature reveals that although the influence of infrastructural drivers on online shopping has been proposed, not much has been done to test the conceptual linkages empirically. Sheth and Sharma (2005) and, more recently, Das et al (2014), while hypothesizing the effects of infrastructural drivers on online consumer behaviors, recommended that empirical studies should be conducted to test the proposed relations. Markus and Soh (2002) also suggested the importance of focusing on structural factors to explain differences in e-commerce activities across countries.

This study responds to the need for filling the gaps in the literature by examining the effects of three national level infrastructural drivers (telecommunications, financial, and regulatory) on online shopping expenditures in 43 countries. Findings from this study would contribute to our understanding of the effects of national-level infrastructural drivers on online shopping expenditures across countries. Below we present hypotheses related to the effects of regulatory (H1), telecommunications (H2 and H3), and financial (H4 and H5) drivers on online shopping expenditures.

3. HYPOTHESES

Privacy, as a psychological construct, is deeply embedded in the culture of a country. The desire to maintain privacy manifests itself in different types of behavior. In the online environment, for example, privacy concern has been shown to influence risk reduction behaviors (Phelps et al., 2000; Youn, 2009). Wirtz, et al. (2007) found that heightened privacy concern among consumers resulted in their engaging in different forms of risk reductions strategies such as fabricating personal information, using privacy-enhancing technologies, or even refusing to purchase. Besides influencing risk reduction behaviors, privacy concern also affects online transactional behaviors. When privacy concern increases, both the frequency of online transactions and online spending are negatively affected. Zorotheos and Kafeza (2009) found that when consumers were concerned about privacy, they were less likely to transact on websites that required personal information. Dubelaar et al. (2003, p. 70) summarized the linkages between privacy and shopping behavior by noting that the "perceptions of personal information privacy are directly linked to on-line purchasing behavior."

Privacy concern is salient because of the massive amount of personal data that businesses collect to construct consumer profiles and develop marketing strategies. The concern about privacy is exhibited in what consumers want to reveal about themselves and the control they want to exercise over how personal information is acquired and used (Westin, 1967). In a survey, about 92% of the respondents indicated that they worry about their online privacy, while 74% said that they are more concerned about privacy now than they were a year ago (Bachman, 2013). Surveys and polls also show the concern that consumers have about the loss of privacy. In a multinational poll, about 80% of consumers in the United States, 79% in Germany, and 68% in the United Kingdom agreed that consumers have lost control over how companies collect and use personal information (IBM, 1999). In a recent article in *The Wall Street Journal*, 86% of Internet users reported taking steps to remove or mask their digital footprints and 68% of Internet users felt that privacy laws did not adequately protect them (Dwoskin, 2014).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

In light of the concern that consumers have about privacy, many solutions have been proposed to protect privacy, including self-regulation by businesses, development of corporate business and ethical policies, as well as changes to public policy (Caudill and Murphy, 2000). While different proposals have been made to protect privacy, very little empirical work has been done to test their effectiveness (Caudill and Murphy, 2000). The growing concern about the invasion of privacy is also attributed to the lack of legal frameworks to counteract such invasions (Wijnholds and Little, 2001). When robust and adequate privacy protection regulations are in place, consumers would feel less concerned about interacting with a website (Wirtz et al. 2007). It has also been suggested that regulatory actions to protect privacy would be shaped by consumers' concerns within countries (Singh and Hill, 2003). Bellman et al. (2004) noted that the high level of privacy concern is reflected in the enactment of privacy legislations in several countries. It can thus be expected that in countries where privacy protection is enforced stringently, consumers would feel more comfortable in using the Internet for making online purchases. Therefore, the following is proposed.

H1: Higher privacy protection enforcement is associated with higher levels of online shopping expenditures.

An efficient telecommunications infrastructure is essential for the smooth conduct of online shopping activities. Simon (2004, p. 35) noted that a "country's readiness for e-commerce depends on network infrastructure." The underlying foundation of the Internet is technological and, therefore, online shopping expenditures would be high in countries where significant investments in telecommunications infrastructure have been made. Data also show that differences exist among countries in the level of e-commerce sales due to differences in telecommunications infrastructure (Ho et al., 2011). Countries that have invested in telecommunications infrastructure provide their citizens greater opportunities to move from the traditional bricks and mortar businesses to the online markets (Oxley and Yeung, 2001). In a more sophisticated telecommunications environment, consumers would be able to easily log on to the Internet, search for product information, compare price, read reviews, and purchase the product. Therefore, the following is proposed.

H2: Higher investments in telecommunications infrastructure are associated with higher levels of online shopping expenditures.

Consumers need to be able to access the Internet to conduct online transactions. Although the Internet seems ubiquitous, access to this technology is not universal. Significant digital access divide exists at the international level, as the Internet penetration varies widely across the developed and developing economies. Comparatively, Internet penetration rates are higher in the developed economies. Increased access to the Internet enables people to engage in different types of online activities including online shopping. The level of Internet penetration would thus represent the size of the e-commerce market in a country (Ho et al., 2011). Countries with higher Internet penetration rates will thus show higher levels of online shopping. Therefore, the following is proposed.

H3: Higher Internet penetrations are associated with higher levels of online shopping expenditures.

Income provides consumers the financial means to make a purchase. The level of income also influences the perception of the value of time. As income increases, the perceived monetary value of time also

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

increases. Thus, people with different levels of income would value the time spent on making a purchase differently. As higher income people would place greater monetary value on time, the opportunity costs of the time spent on the different phases of the purchasing process will be higher for them. They will thus be more inclined to making purchases on the Internet to save time.

Although the purchasing power and opportunity cost arguments suggest a positive link between income and online buying, empirical data on the impact of income on online transactions show mixed results. Patwardhan and Yang (2003) found income to be not a significant predictor of online shopping, whereas Goldsmith and Flynn (2005), Hannah and Lybecker (2010), and Lohse et al. (2000) found income to be positively related to online shopping, frequency of online shopping, and spending. Taking into consideration the argument that the value of time increases with rising income and that the variety of purchases that consumers make also increases with rising income, we argue that as per capita income increases online shopping will also increase. Therefore, the following is proposed.

H4: Higher per capita gross national income is associated with higher online shopping expenditures.

The online shopping environment is especially suitable for the use of credit cards (Bulut and Koprulu, 2010). In the online environment, credit cards serve as a convenient mechanism for making a purchase (Oxley and Yeung, 2001). After the purchase decision has been made, consumers can provide credit card information to the firm and complete the transaction. The advantage of using credit cards is that payments for purchases are deferred to the next billing cycle when it can be paid in full or in reduced monthly installments. Research also shows that consumers enjoy the convenience of using credit cards and thus tend to overspend (Gan et al., 2008). While the availability of credit cards makes it convenient to conduct online transactions, data show that consumers do not enjoy the same level of access to this financial instrument across countries. Credit card penetration varies across countries and in countries where penetration is high it can be hypothesized that online shopping would also be high. Markus and Soh (2002) noted that availability of credit cards in the financial infrastructure can explain differences in e-commerce activities across countries. Kenny (2003) had also noted that lack of credit cards can restrict the use of the Web for transactional activities. Therefore, the following is proposed.

H5: Higher credit card penetration is associated with higher online shopping expenditures.

4. METHOD

The multiple regression technique was used to test the proposed hypotheses. The statistical procedure measures the degree to which each of the independent variables contributes to the prediction of the dependent variable. The dependent variable was per capita online shopping expenditures. The five independent variables were privacy protection enforcement, per capita telecommunications investments, Internet penetration, per capita income, and credit cards penetration. Privacy protection enforcement reflects the regulatory infrastructure driver. Per capita telecommunications investments and Internet penetration reflect the telecommunications infrastructure drivers. Per capita income and credit cards penetration reflect the financial infrastructure drivers.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.1. Sample

In conducting international research involving secondary data, researchers generally end up working with the sample of countries on which data are available. They, thus, confront two key questions, one dealing with sample size and the other dealing with the appropriateness of the data for testing the hypotheses. For this study, the size of the sample was determined by the availability of data on all six variables. Data on all six variables were available for 43 countries, which constituted this study's sample size (see Appendix A for the list of countries). The sample size of 43 is considered appropriate for conducting regression analysis.

4.2. Variables

Privacy enforcement rankings for the sampled countries came from Privacy International, an organization created jointly by US-based Electronic Privacy Information Center and the UK-based Privacy International (Privacy International, 2007). The data that Privacy International provides is based on a comprehensive survey of global privacy enforcement and has been used in existing research (Bellman et al., 2004). The international ranking of privacy enforcement in each country is based on the following criteria:

- Is there a regulatory body with sufficient powers to investigate privacy infractions?
- Can the regulator act proactively?
- Does the regulatory body act in an effective way?
- Have cases been taken through the administrative and legal systems?

Each of the above-mentioned criteria relates directly to the ability and willingness of governments and policy makers to enforce privacy within their countries. Privacy International measures the level of enforcement in each country on a scale of 1 through 5, with 1 representing lax privacy enforcement and 5 representing stringent privacy enforcement. The data provided by Privacy International was used in this study.

For telecommunications infrastructure drivers, the two variables were telecommunications investments and Internet penetration. Telecommunications investment was measured as the expenditures associated with acquiring the ownership of telecommunication equipment infrastructure, which include land, buildings, and computer software. The expenditure included both new installations and additions to existing installations. Total investment was divided by population to obtain per capita investment in telecommunications infrastructure. Internet penetration was measured as the percentage of population with access to the Internet.

For financial infrastructure drivers, the two variables were per capita national income and credit card penetration. Per capita income data was obtained by dividing the gross national income of the country by its population. Credit card penetration was calculated as the number of credit cards per thousand people in each country.

The dependent variable was per capita online shopping expenditures which included sales generated through pure e-commerce websites and through sites operated by store-based retailers. Sales data is attributed to the country where the consumer is based, rather than where the retailer is based. It thus represents online shopping within each country. Data on the dependent variable and telecommunications and financial drivers were obtained from Euromonitor International (2014).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Regression Model Coefficients

Variables	B	Std. Error	β	t-value	Sig.
(Constant)	-31.342	45.806		-.684	.498
Privacy Enforcement	-15.934	14.498	-.122	-1.099	.279
GNI Per Capita	.004	.002	.523	2.514	.016
Percent of Net Users	.776	1.120	.118	.693	.492
Credit Card Penetration	-.004	.029	-.016	-.136	.892
Telecomm Infrastructure	.293	.144	.291	2.040	.049

Dependent Variable: Per capita online shopping expenditures

4.3. Results

Results from the multiple regression analysis show the significance of telecommunications and financial infrastructures in explaining per capita expenditures on online shopping. The significant variable in telecommunications infrastructure drivers was per capita telecommunications investments and the significant variable in financial infrastructure drivers was per capita income. Results also show that privacy protection regulations, Internet penetration, and credit card penetration were not significant (see Table 1 for parameters estimate and significance level). The overall R-square for the proposed model was .699.

5. CONCLUSION

Findings support the hypotheses of positive influence of per capita telecommunications investments and per capita income on online shopping expenditures. A developed telecommunications infrastructure creates a transactional environment that is conducive to the growth of online shopping. As the ease of using the Internet for transactional purposes increases, consumers tend to spend more money on online shopping. Expenditures on online shopping also increase as consumers' income increases. Consumers with higher per capita income spend more on online shopping.

This study also hypothesized positive association between privacy protection regulations and online shopping. It was argued that with more stringent privacy enforcement regulations, consumers would feel more confident about privacy protection and thus would be less inhibited in making online purchases. Although this line of reasoning led to the above stated hypothesis, the result did not support the proposed linkage. However, what should be noted is that the non-significance of privacy regulations does not mean that consumers do not value privacy. This would not be a justifiable conclusion as the finding of this study is not based on whether people knew about the regulations or how they perceived them. What can be concluded, based on the finding, is that the stringency of privacy protection regulations did not significantly influence per capita expenditures on online shopping.

Internet penetration, the proportion of people with access to the Internet, was non-significant in explaining per capita expenditures on Internet shopping. What this could suggest is that the ability of people to access the Internet does not make them more inclined to spend more on online purchases. Credit card penetration was also non-significant. The proposal of positive association between credit card penetration and online shopping expenditures was based on the argument that consumers would

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

find the convenience of using credit cards to make online purchases appealing. Therefore, the higher the credit card penetration, the higher would be the expenditures on online shopping. The lack of significant relation between credit card penetration and online shopping can be traced to consumers' preference for using cash rather than credit cards (Slyke, et al. 2005). Studies show that Germans and Belgians, for example, do not like to use credit cards for making payments (Harrison-Walker, 2002).

5.1. Theoretical Implications

Existing research has focused mostly on demographic characteristics and psychological variables to understand consumers' online shopping behavior. Our research objective was to add to this literature by examining the role of infrastructural drivers in influencing per capita expenditures on online shopping. Per capita telecommunications investment was found to be a significant facilitator of online shopping expenditures. Online transactions are conducted on the telecommunications infrastructure, and thus the more advanced this infrastructure is the easier it is for consumers to make online purchases. When consumers can search product related information, compare product offerings, and make and execute purchase decisions easily and quickly, they become more likely to make purchases and spend more. An efficient telecommunications infrastructure, resulting from investments in its development, serves as a digital highway for the smooth flow of information, facilitating interactions between consumers and online businesses. Thus, differences across countries in investments made in the telecommunications infrastructure would explain variations in per capita online shopping expenditures.

With respect to the financial driver, per capita income was found to be a significant facilitator of online shopping expenditures. As per capita income increases, online shopping expenditures also increase. The significant finding supports the argument that higher levels of income give people the discretionary purchasing power that results in higher levels of expenditures on online shopping. The finding also supports the argument that as income increases, the opportunity costs of time spent on making a purchase increase. People with higher income would thus find the convenience of buying online appealing and, furthermore, as they make a variety of purchases due to higher income, the amount of money they spend on online shopping would also increase.

5.2. Managerial Implications

Managerial implications of findings from this study relate to two key strategic decisions that firms make: how to select international markets and how to develop them. For firms wanting to succeed internationally, the selection of markets plays a decisive role. The growth of international sales is predicated on how well a firm is able to analyze and select country markets. Among the different steps of the international market selection process, market analysis occupies a key position, acting as a bridge between the decision to internationalize and the selection of markets. Thus, the knowledge of the variables that affect online sales potential in different country markets would be considered highly valuable to firms. Findings from this study show that countries that have invested more on telecommunications infrastructure and have high per capita income will have higher levels of online sales relative to countries that have invested less and have low income.

Higher levels of telecommunications infrastructure and income are linked with more developed and competitive markets. In these country markets, not only the propensity to spend more on online purchases but also competitive intensity would be high. In contrast, countries which have embarked on developing

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

their telecommunications infrastructure and are expected to increase per capita income would experience an increase in online sales in the future. Thus, the managerial implication relates to selecting a country market that is either developed or has the potential to develop.

Another implication, although not directly flowing from the findings, covers the issue of market development. After a market is selected, firms face the difficult question of market development. For online businesses, this involves the development and continuous enhancement of websites to increase sales. Quelch and Klein (1996, p.72) noted that firms will have to strategize on how to "maintain, grow, and manage their sites." The recommendation is that firms need to develop country-specific websites if they wish to exploit the differential international marketing opportunities. Although English is considered the global language of commerce, its exclusive use would make some international consumers feel that they are not welcomed. In addition, when developing the websites, firms need to understand that there are cross-cultural differences that influence how consumers may respond to the different elements of a website such as color, font, logos, and images (Harrison-Walker, 2002).

5.3. Limitations and Future Study

The limitation of this study relates to the sample size, as the analysis was conducted on a small sample of countries. While this limitation can affect the validity of findings, it is generally unavoidable in international studies that are based on secondary data. With respect to this study, however, the sampled countries cover two key characteristics that allay the concern about the validity of findings. First, they come from different regions of the world and, second, they include countries that are at different stages of economic development (see Appendix A). These two characteristics enhance confidence in the validity of the study's findings.

This study opens several avenues for future research. However, the three areas that seem promising are the following. First, future research can examine the level of awareness among people about the different aspects of privacy-related regulations and how this awareness affects online behaviors. Second, future research can explore whether consumers trust that privacy regulations are there to protect their interests and how this trust shapes their online behaviors. Third, future research can focus on the tradeoffs between privacy and convenience, that is, how much privacy people are willing to sacrifice to enjoy the convenience of using the Internet for transactional purposes.

ABSTRACT

This article describes how in the modern era e-commerce is growing exponentially and the consumers are more likely to shop online. The purpose of this article is to assess the relationship between website quality and the online impulse buying behavior (OIBB). This article further explores the moderating role of sales promotion and online impulse purchasing. Data were collected from 704 online shoppers from two cities, Beijing and Tianjin. Structure equation modeling (SEM), reliability, and validity were employed to test the proposed hypotheses. Findings show that all exogenous factors i.e. website quality, urge to buy, positive effect of emotions, significantly influence online impulse buying; whereas the effects of negative emotions have failed. Sales promotions and the use of credit cards positively moderates the relationship between website quality and online impulse buying. Theoretical and practical implications for managers and academic practitioners are discussed.

INTRODUCTION

Internet plays a vital role in everyone's life. In China, a massive population buys online to conserve time and efforts, and to espouse the individuality culture (Pei et al., 2016; Wang, 2017). According to the 2015 China online shopping report, the Chinese GMV (Gross merchandise volume) amounted to 2.8 trillion Yuan in 2014, jumping up by 47.4% on a YoY (year on year) basis. This growth was more than 4 times faster than the total retail sales of consumer goods. Moreover, its penetration in total retail sales of consumer goods also exceeded 10% for the first time in Chinese history, which serves a healthy opportunity for the online retailers to focus on online shoppers. A huge sum of shoppers purchased products spontaneously. With the growing significance of online shopping, a deeper understanding of impulse buying on the internet has become a necessity (Floh & Madlberger 2013). According to some studies, almost 40% of the online shopping's are counted as impulse purchases (Verhagen & van Dolen 2011; Liu et al., 2013). Hausman, (2000) argued that 30-50% of all retail sales are triggered by impulse purchases, while 90% of consumers buy goods impulsively on occasions. Many online retailer setups are working on online impulse buying to exploit greater opportunities to attract and retain the consumers.

The China Internet Network Information Center's (CNNIC) January 2017 report discloses that with an annual increase of 42.99 million Internet users China's Internet user population has reached 731 million, with a penetration rate of 53.2%, up 2.9 percentage points from the end of 2015. China has now become the largest Internet market in the world. Millions of netizens are surfing the Internet to acquire information about products and services, and are often even spending more time on online purchases than their genuine requirements. According to CNNIC report, direct messaging is very often used mobile apps among Chinese internet users in 2016. Furthermore, finding shows that 79.6% of Chinese internet users use WeChat app that is the very big figure as compare to netizens who used QQ 60.6%. Taobao 24.1%, mobile Baidu 15.3%, and Alipay 14.4% are the third, fourth and fifth rank of Chinese internet users.

Impulse Buying behavior is very common amongst the consumers around the world. Dawson and Kim, (2010) argued that 50 percent of consumers buy goods impulsively. To boost the impulse purchases, retailers readily focus on product displays, store designs, and package designs to attract and hold the shoppers' attention (Lee and Kacen, 2008). Existent research shows that almost any items might be purchased on impulse (Rook and Fisher, 1995; Kacen and Lee, 2002). Although impulse buying is a phenomenon that is most likely to hold for inexpensive items, the expensive items may also be dealt with (Rook and Fisher, 1995).

In principle, impulse shoppers may usually not control their inherent behaviors to visit online stores (Wells, Parboteeah, & Valacich, 2011). Online shoppers are involved in discrete psychological states of unplanned and sudden behaviors towards a buying decision process, which is very difficult to understand for retailers (Floh & Madlberger 2013). For the Internet user perspectives, online shoppers/ consumers are website users for executing all functions of an electronic store towards finding and searching the information of the related product, tracking product delivery and complete payment system. Therefore, the usage of website technology and belief trust on e-stores are two significant concerns for online impulse buying (Wu, Li, & Fu, 2011; Wu, 2013). These concerns are very important to determine for online impulse buying shoppers.

The growing veered of online shopping has motivated the need to study OIBB under recent trends (Floh & Madlberger 2013). Previous researchers have recommended several perspectives to better un-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

derstand the online impulse buying behavior. Some studies have suggested shopping enjoyment effect as a mediator to direct the OIBB from the website's interaction experience (affective) and websites' usefulness for shopping task (cognitive) (Koufaris, 2002; Parboteeah, et al., 2009). Other studies have focused the importance of electronic store characteristics (design, content, and navigation) as the antecedents of repelling online impulse buying behavior through a mediator of shopping enjoyment and effective perception (Floh & Madlberger 2013).

A number of studies conducted to examine decision-making mechanisms of consumer's impulse in online environments. For instance, a few studies have found the utilization of environmental psychology to investigate how website attributes, such as site's ease of use, visual appeal, and information fit-to-task affect personality and consumers' emotions causing online impulse shopping decisions (Parboteeah, et al., 2009; Verhagen & van Dolen 2011; Wells, et al., 2011). These studies recommended that IS wisdom and integration of marketing would increase the knowledge on online impulse buying (Verhagen & van Dolen 2011; Wells, et al., 2011). Earlier IS studies investigated how three factors of perceived website attribute namely product availability, website's ease of use and visual appeal, interact with consumers' personalities to seduce impulse buying. In the technical perspective, former studies have mainly emphasized upon the user' interaction with the website, such as the navigation ability, pleasantness, visual attraction, and the security (Luo, Ba, & Zhang, 2012; Floh & Madlberger, 2013). The said features can broadly be explained as website design/ quality. Shen & Khalifa, (2012) described that perceived usefulness, shows the degree to which online consumers believe that shopping productivity can be increased by using a specific website.

Although largely available researches have addresses this issue, little is known about it in Chinese context. China is known as having the world's largest number of netizens. Considering this fact, present study provides an in-depth understanding of the primary motivations, attitudes, and behaviors of Chinese online shoppers. To address the rapid trends of ecommerce in China, retailers need recommendations to cater future endeavors and expansions. This very need is expected to be met by this study which analyzes the relationship of OIBB with website quality by incorporating the moderating effect of sales promotion and use of credit card. In specific, those who want to conduct research on China's B2C Internet market with the perspective of online impulse buying by affecting the website attributes may be the direct beneficiaries of this study. A lot of Chinese retailers attracting more consumers who purchased goods online by growing e-commerce platforms that are repelling B2C online retailing market growth (Su, 2009).

Although a voluminous research can be found on impulse buying behavior, these studies do not embrace the emerging face of impulse buying i.e. OIBB. Moreover, all of these studies have been conducted on developed economies, leaving behind the need to investigate this issue in an emerging economy like China which houses the largest number of netizens ever. The objective of this study is to fourfold: (a) to examine the relationship between website quality and OIBB (b) to assess the impact of positive and negative emotions on OIBB (c) to identify how sales promotion and use of credit card moderate the relationship between website quality and OIBB? (d) to investigate the impact of the urge to buy on OIBB.

With the aforementioned relevance, firstly this manuscript provides the literature review by contributing to the hypothesized relationship between the variables adopted by research methodology and study analysis. Then the later parts associated with results and discussions, implications for managers are demonstrated. And finally, the last part deals with conclusions, limitations and future directions.

HYPOTHESES DEVELOPMENT

Online Impulse Buying Behavior

Impulse purchase happens when a consumer experiences sudden, habitually powerful and insistent urge to buy something immediately (Liu et al., 2013; Akram et al., 2017). Impulse buying occurs during shopping from a particular stimulus (Floh & Madlberger, 2013). Impulse buying as an unplanned purchasing decision is influenced by several factors (Ozen & Engizek 2013; Akram et al., 2017). The stimulus can be an extrinsic characteristic of the product or actual product itself, such as searching instruments or the information about the product. Yu & Bastin, (2010) mentioned that several factors e.g. personality, time pressure, location, cultural factors and variety of economic positions influences on impulse buying behavior. From a Psychological perspective consumer's impulse buying behavior is occasionally irresistible because the inception of a psychological impulse buying often occurs not just spontaneously but also suddenly (Sharma et al., 2010). Usually, high tendency of impulse consumers probably go through spontaneous buying behavior and their shopping lists have space for unexpected buying intention (Park, et al., 2012).

When consumers make a decision to buy online, they often act impulsively and are triggered by easy purchasing, easy access to product e.g., click ordering, painless delivery, and absence of social pressures (Jeffrey & hodge, 2007). In specific, few researches have focused on the role of impulsive buying in online buying (Floh & Madlberger, 2013; Liu et al., 2013). Liu et al., (2013) investigated how website characteristics (ease of use, product availability, visual appeal etc.) effect consumers' individual traits, including instant gratification, normative evaluation and impulsiveness.

In the online context, innovations and improvements in the field of e-commerce are causing a surge in online shopping. According to Dittmar et al., (2004) the reason why many shoppers overspend in online transactions is that the virtual procedure does not feel like spending high money on shopping. Online transaction plays a vital role for online retailers as well as organizations because they make strategies to motivate the consumers buy more products. Many of the previous studies on impulse buying behavior focused on brick and mortar stores (Jeffrey & hodge, 2007). Only a few studies actually discoursed on consumer's impulse buying in an online setting - and that too with different angles. For instance, Zhang et al., (2008) explored the influence of consumers' general tendency to buy impulsively based on Technology Acceptance Model (TAM) and observed small yet significant direct effects. Park et al., (2012) typically investigated impulse purchasing for clothing products in the internet context. Verhagen & Van Dolen, (2011) studied the influence of online store beliefs on consumer's online impulse buying behavior.

Website Quality

Advent literature suggests various attributes of website that may enhance its quality. Wolfinbarger and Gilly, 2003) highlighted the significance of website design and contents that may enhance its quality to attract more online customers. Contents presents the services offered and design means how to present that content in attractive way to customers (Huizingh, 2000). Website features visual appeal, transaction safety and navigation are all special signs that can directly influence to attract the consumers experience impulse purchases (wells et al., 2011). Childers et al., (2001) suggested a term called "web atmospherics" in online setting, which includes website design features as graphics, frames, pop-up windows, search engine configuration, text, hypertext links, "one click" purchase procedures or check-out, site layout

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

dimensions and media dimensions. These attributes of web design may lead to triggering online impulse buying to a different level. Loiacono et al., 2007 presented four distinct types of website quality; usefulness, ease of use, entertainment and complementary relationship. Ranganathan and Ganapathy, (2002) contemplated design, privacy, information content and security of website as four important dimensions of B2C website. Likewise, Elliott and speck (2005) examined that consumer's attitudes towards retail website is significantly affected by five website elements i.e., product information, ease of use, currency trust and entertainment.

Several studies found that website quality attributes effect significantly on consumer's online impulse buying behavior. For instance, Turkyilmaz et al., (2015) reveal that three dimensions of website quality including entertainment, ease of use and usefulness have positive effects on consumers online impulse purchase whereas complimentary relations have no influential impact. Well-designed interface enhances the probability of consumers' impulse buying (Hoffman and Novak, 1996, Wolfinbarger and Gilly 2003, Shergill and Chen, 2005). Turkyilmaz suggested that Online retailers, who want to strengthen their customer base and retain it, must emphasize and improve the quality of website, failure to which may lead to breaking up customers (Turkyilmaz et al., 2015).

Aforementioned discussion leads us to formulate following hypothesis:

H1: There is a positive relationship between website quality and online impulse buying behavior.

Sales Promotion

Sales promotions, as a collection of various motivational tools, are designed to stimulate consumers to purchase numerous products or services within short periods of time (Kotler, 2012). Sales promotions intend to stimulate consumers' needs and urges customers to buy product immediately of a specific brand. Battberg and Neslin (1990) emphasized on significant promotions objectives which include; (1) enhancing store image, (2) generating store traffic, (3) creating price image and (4) moving excess inventory. Sales promotion is very important and considerable part in an online shopping environment and in advertising strategy.

Many studies have identified the sales promotion as a mean to increase customer base gradually. For instance, in the US number of homes that use online coupons for shop online has been increasing abruptly (Forrester, 2014). Additionally, studies have recommended that internet connectivity has provided a means for mass customization of sales promotions by targeting individual buyers on seller's website (Kannan and Kopalle 2001). Sales promotions stimuli and online store design features are very important antecedents of consumers online impulse purchase. Sales promotion stimuli, sales (e.g., markdown. clearance), promotions (e.g., cash rebates, buy one get one free, gifted certificated), suggestions (e.g., bundling), and purchase ideas (e.g., new arrival products and one-stop shopping) that can persuade consumers to buy impulsively (Dawson & Kim, 2010). Dawson and Kim (2010) also investigated that consumers' online impulse buying is related with e-retailer's sales promotion stimuli which can therefore be regarded as another factor influencing this behavior. Sales promotion influences the consumer's online impulse buying behavior positively (Badgaiyan et al., 2015).

Contrary to well established positive relationship of OIBB with sales promotion, Blattberg et al., (1981) found that sales promotion, particularly price discount has negative affect sales due to purchase acceleration and stockpiling, and negatively impact brand image and reference price (Grewal et al., 1998).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Nevertheless, if customers of the product under sales promotion are resellers instead of consumers, such this negative effect could be slightly decreased.

According to the above studies we proposed two hypotheses sales promotion as direct effect and moderation effect between website quality and online impulse buying behavior.

H2: There is a positive relationship between sales promotion and online impulse buying behavior.

H3: Sales promotion positively moderate the relationship between website quality and online impulse buying behavior. Such that the relationship is stronger when the sales promotion is higher, the relationship is weaken when the sales promotion is lower.

Use of Credit Card

Credit card is the kind of plastic money, which is rapidly used among consumers. In Psychological perspective, credit card is a trigger of spending behavior. Feinberg (1986) provided evidence those college students who use credit cards, purchase more and prompt as compares to students who use cash. The use of credit card stimulates the consumers spending as compared to cash transactions. For instance, credit cards increase the sales of fast-food restaurants and the transactions that are 50 to 100% larger than cash dealings in US. Hayhoe et al., (2005) studied on college students in southern states of the USA, concluded that credit card is very important for young shoppers, they prefer to buy through this medium than their non-user counterparts to money as a symbol of power. Extensive use of credit cards imitates the shoppers' partialities regarding prearranged list of credit, with the help of technological advancements make it easier for consumers to offer revolving credit (Durkin, 2000). Soman (2001) argued that those consumers usually used credit card, they always spend extra on purchasing.

Credit card use is also one of major contributor in online shopping, but only sparse studies have taken it into their consideration and there is also need to analyze its role in online impulse buying behavior. Credit card use play a vital role to buy impulsively, Badgaiyan (2015) found that the credit card use has a positive influence on impulsive purchase; it should have been advocated rise up the chances of impulse buying behavior. Importantly, credit card use results in buying online impulsively (Roberts and Jones, 2001; Kim, 2006). Karbasivar, (2011) found that credit card use positively relates with consumers IBB in the setting of apparel products. Easily accessible credits cards eradicate the abrupt need for money to purchase something, since overspending of consumers (George, 1998) and enhance the advancement of impulse purchase (Robert and Jones, 2001).

In the light of above studies, we proposed two hypotheses credit card use with online impulse buying behavior.

H4: There is a positive relationship between use of credit card and online impulse buying behavior.

H5: Use of credit cards among Chinese consumers positively moderate the relationship between website quality and online impulse buying behavior. Such that the relationship is stronger when the use of credit card is higher, the relationship is weaken when the use of credit card is lower.

The Influence of Emotions on Online Impulse Buying

Browsing is in-store examinations of a retailer's merchandise for informational and recreational objectives without a sudden intention to purchase. Positive emotions were discovered positive impact on browsing

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

setting such as spend more time on buying; this kind of behavior leads to online impulse buying. Many emotional kinds effected assessment decisions and determined that online setting generate pleasure explorations (Huang, 2005). Additionally, she recommended that negative emotions such as monotony will drive away customers and negative impact on assessment behavior (Verhagen and van Dolen, 2011). Many scholars found that affect influences on impulse shopping: when shoppers encounter the positive affect, the incline of shopper is more likely to engage in process than avoidance behavior. According to (Verplanken and Herabadi, 2001) highly positive emotion felt by a shopper leads to impulse buying and overspending. Therefore, we proposed following hypotheses:

H6a: Positive emotion positively influence on online impulse buying.
H6b: Negative emotion negatively influence on online impulse buying.

Urge to Buy Impulsively

The impact of browsing has been contended to be a central component in the spontaneous shopping procedure. In the event that shoppers browse longer, the will experience high stimulus, expanding the probability of impulsive buying (Park et al., 2012). According to Verhagen and van Dolen, (2011) urge to buy is a major predictor of online impulse buying and significantly and positively influence on impulsive buying in online setting. Therefore, we proposed following hypothesis:

H7: Urge to buy positively influence on online impulse buying.

Mathematical Model:

$$OIBB = \beta_0 + \beta_1 (WQ) + \beta_2 (USFN) + \beta_3 (EOU) + \beta_4 (ENT) + \beta_5 (CR) + \beta_6 (SP) + \beta_7 (UTB) + \beta_8 (PA) + \beta_9 (NA) + \beta_{10} (UCC) + \varepsilon$$

RESEARCH DESIGN AND METHODOLOGY

Procedure

This manuscript intends to investigate how website quality affects the online consumer's impulse buying behavior with moderator variables such as, sales promotion and use of credit card. To identify the qualified respondents (having exposure of online buying) in this environment was needed, we used a questionnaire that was originally developed in English,but converted into Chinese and then back translated into English to cross check the validity of translation; after that ICTC, BUPT (International Chinese Training Center, Beijing University of Posts and Telecommunications) compared it with the original questionnaire. ICTC selected 10 students at master's and PhD level for pretesting and to ensure the accuracy of the translation, after that these students discuss interpretation and clarity with the two Chinese teachers (who taught Chinese language to the international students) and with research team to discuss and suggest improvements.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Data was collected from two ways; first, online survey and second; paper questionnaire. In an online survey, random sampling survey problem is always there, because many studies have used the self-selected sampling procedure for non-probability sampling e.g., convenience-sampling technique. This study tries to mitigate this problem by selecting the participants randomly from many online community sources and select the different time slots for every community. Online survey was conducted for various bigger online communities at the same time, such communities includes, Wechat, facebook, linked in, Weibo, and QQ as all Chinese consumers use one of these or more social network applications. Additionally, 12 distinct time slots were used in this study in terms of a two hours' interval on daily basis. We haphazardly selected time slots on daily basis from each community to be the response sample. This research conducted online survey between the time periods October-December 2016. This study covers the large and wider data sources to make the sample true representative of population. We offered a reward system for respondents. We randomly selected 60 participants from the sample size and give the reward 10 RMB after the survey.

Online survey has also some demerits, for instance data errors, questions complexity issues, limited respondents, and technical issues. Considering all these issue, we also collected data through paper questionnaire. Two metropolitan and demographically diversified cities of China named (Beijing & Tianjin) were targeted for data collection. Most of the respondents of this study were university student. In order to motivate the online shoppers, after collecting the data from each respondent we give one packet of chocolate as a reward which costs 10 RMB.

Questionnaire was distributed among 900 online shoppers and received 856 back from both online and offline sources, out of which 152 were not valid that further reduces our sample size to 704. Out of 900 questionnaires, 400 were distributed through paper questionnaire and 500 by online.

Instrumentations

This study used existing authenticated scales: Online impulse buying (Verhagen and van Dolen, 2011), website quality (Loiacono et al., 2007), positive and negative effect (Verhagen and van Dolen, 2011), urge to buy impulsively (Verhagen and van Dolen, 2011), sales promotion (Badgaiyan and Verma, 2015), and use of credit card (Badgaiyan and Verma, 2015). This study instrumentation comprised of two parts questionnaires (1) nominal scale (2) five point Likert scale (i.e., 1 = strongly disagree to 5 = strongly agree).

DATA ANALYSIS AND RESULTS

The current study has significant results analyzed by different tools to explore how website quality affects OIBB with two moderators; sales promotion and use of credit card. Unrotated factor analysis to identify the common method bias, convergent validity, discriminant validity, measure the reliability by Cronbach's alpha, minimum to maximum item loading, Average Variance Extracted and minimum item to total correlations were examined before employing (CFA) analysis for authenticating the measurements values. (Table 3 and 4). Moreover, moderation hypotheses were tested using three steps moderation regression analysis (Table 6 and 7).

Table 1 shows the demographic information of respondents of survey. All participants contributed voluntarily in survey. Demographic characteristics include gender, age, education, occupation and Online

		Managerial level	45	6.4
		Business	40	5.7

impulse experiences. Results demonstrated that majority of respondents were female (58.2%), and most of the respondents are younger consumers (age, 18-25, 40.6%). Almost all participants were students (3.1.7%) belonging to bachelors and masters level.

Table 2 showed the common method bias from unrotated factor analysis. In a data set, which has issue of common method bias, we do identify a single factor that explains majority of the variance (Podsakoff, MacKenzie, Lee, & Podsakoff, 2003). Several scholars addressed the common method variance issue by using Harman's single factor test technique (Podsakoff et al., 2003). We included all items from all of the constructs in the relationship structure for an unrotated factor analysis to determine whether the majority of the variance cannot be accounted for by one general factor (i.e., more than 50% variance accounted for). The unrotated factor analysis may extract many factors (variables) from all measured items and suggest the variance explained by each of these factors. The results of unrotated factors analysis shows that dependent variables and independent variables extracted the dissimilar factor from results of this analysis. Table 2 showed no single factor having variance more than 50%. The first factor is impulse buying behavior (IBB) with 29.2% of variance explained. Therefore, results showed that there is no issue regarding common method bias. Confirmative factor analysis was utilized to assess the measurement model. The findings show outstanding model fit indices CMIND/df: 2.543, CFI = 0.987, GFI = 0.921, AGFI = 0.976, NFI = .0954, RMSEA = 0.031. All values of CFA analysis meet the threshold value and show the satisfactory properties.

Multicollinearities were examined in this study by using Variance Inflation Factor (VIF) analyzed by SPSS. The value of VIFs are 3.40 (impulse buying behavior), 2.34 (sales promotion), 3.11 (urge to buy), 3.76 (positive affect), 2.33 (negative affect), 2.12 (use of credit card), 3.35, 2.54, 4.53, 3.60 (usefulness, ease of use, entertainment, and complimentary relation for website quality); all values are below threshold

10 (Diamantopoulos & siguaw, 2006). Further, Validity and reliability were calculated in the measurement model. Cronbach's alpha and composite reliability were used for examining the reliability. According to Chin, (1998) the acceptable values for both should be ≥ 0.80. Convergent validity and discriminant validity were used to assess the validity of scales. Convergent validity is evaluated from three criteria: (1) item loading (λ) higher than 0.70 and it should be significance, (2) composite reliability for every construct and it should be higher than 0.80 and explain same like cronbach'α reliability, (3) should be larger than .50 (Hair et al., 2010). Finally, discriminant validity is evaluated by using the comparison between square root of average variance extracted (AVE) for each construct and its squared correlations with all construct. The value of (AVE) should be larger than its correlations (Hair et al., 2010).

Table 3 shows the values of reliability (α) and convergent validity. First the values of item loadings of all constructs are higher than 0.70, the value of composite reliability is higher than 0.8 and it ranges from 0.81-0.9 and the value of Cronbach' α is larger than 0.80 and it ranges from 0.80-0.90 and all values

Table 3. Descriptive statistics, reliability and convergent validity, (n= 704)

Constructs	Items	Mean	S.D.	Item Loading	Composite Reliability	AVE	Cronbach'α

of AVE is larger than 0.50 and rages from 0.72-0.88. Over all the results of Table 3 reported high level of reliability and outstanding convergent validity AVE >.05, CR >0.80, α >0.80. For the assessment of sampling adequacy Kaiser-Meyer-Olkin (KMO) test was utilized. The value of Kaiser-Meyer-Olkin (KMO) is 0.9 it is valid with threshold value (>0.5) for KMO test (Hair et al., 2010). To examine the discriminant validity, we used Heterotrait-monotrait (HTMT) technique suggested by Henseler et al., (2015) because this technique counters the good results of AVE-SE (Voorhees et al., 2016). Table 4 indicated the results of discriminant validity to ensure that every variable in model is really distinct with $HTMT_{inference}$ and $HTMT_{0.90}$.

Hypotheses Testing Results

The results of SEM: CMIN/DF: 2.111, $p < 0.001$, CFI = 0.98, GFI = 0.88, AGFI = 0.97, NFI 0.98 and RMSEA = 0.032 and the results of structure model shows outstanding goodness-of-fit. The structure model depicts that all hypotheses were supported. This study has some interesting results while testing hypotheses. usefulness, ease of use, entertainment and complimentary relations were indicated as important antecedents of website quality ($\beta = 0.165_{UFLN}$, $\beta = 0.214_{EOU}$, $\beta = 0.153_{ENT}$, $\beta = 0.360_{CR}$). H1,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H2, H4, H6a, H6b and H7 were all substantiated. First we elucidate direct effects hypotheses with online impulse buying behavior. Website quality with four combined antecedents has significant positive impact on online impulse buying $R^2 = .490$ with $\beta = .718_{(WQ \rightarrow OIBB)}$, $p < .05$ which means 49% of variance in dependent variable online impulse buying behavior is due to website quality, Hypothesis 1 is thus supported. Before using the sales promotion and credit cared as moderators, we checked their direct effect on OIBB. Sales promotion showed a significant effect on online impulse buying $R^2 = 0.510$, $\beta = 0.316_{(SP \rightarrow OIBB)}$, $p < .000$. Hypothesis 2 is also supported. H4 was also supported as used of credit card were found to have positive and significant impact on online IBB $R^2 = .525$, $\beta = .119_{(UCC \rightarrow OIIBB)}$, $p < .05$. Overall model R^2 was amounted 0.67 (67%).

Table 5. Hypotheses results

Hypotheses	Path	β	Sig.
H1	website Quality → online impulse buying	0.718	<0.001
H2	Sales Promotion → Online Impulse Buying	0.316	<0.001
H4	Use of Credit Card → Online Impulse Buying	0.119	<0.001
H6a	Positive Affect → Online Impulse Buying	0.34	<0.05
H6b	Negative Affect → Online Impulse Buying	-0.29	0.01
H7	Urge to Buy → Online Impulse Buying	0.45	<0.001

Table 6. The moderation analysis of sales promotion

	β	*t*-Value	*F*	R^2	Adjusted R^2	ΔR^2

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The results of moderation effect are showed in Tables 6 and 7. The value of R^2 of website quality was .490. The coefficient value of sales promotion is ($\beta = .316$) which means sales promotion has a significant and positive relationship with online impulse buying behavior. In third step $\mathbf{\Delta}R^2$ identified from integration term (website quality × sales promotion) was .003. It Means website quality and sales promotion explained additional 3% of variance in online impulse buying behavior. The total effect of interactional term was ($R^2 = .513$) which means both variables jointly explained 51.3% variance in online impulse buying behavior ($\beta = .230$). Hypothesis 3 is accepted (see Table 5). Table 7 reports the moderation effects of use of credit card. Use of credit card is an important variable to effect on online impulse buying behavior ($\beta = .119$). The significant interaction effect between website quality and use of credit card ($\beta = .434$) on OIBB was found. The interactional term (website quality × use of credit card) ($\mathbf{\Delta}R^2 = 0.006$) which means website quality and use of credit card both explained additional 6% of variance in OIBB, thus the total effects of interactional term and website quality jointly explained 53.2% of variance in dependent variable online impulse buying behavior *(*$R^2 = .532$*)* and ($\beta = .434$). Hypothesis 5 is supported (see Table 7). Above discussion and statistics indicate the full moderating role of sales promotion and use of credit card in achieving online IBB.

FINDINGS AND DISCUSSIONS

Major Findings

This section discusses the findings obtained by empirically analyzing the data along with their alignment with previously conducted studies in other countries. First determinant of OIBB in our research is website quality. Literature considers it as one of the most important factors in driving OIBB particularly in advent of technology era. Results of our study also support the findings of earlier studied conducted on website features in relation with online impulse buying. Results find that website quality is positively related with OIBB. The results of this study are more or less similar with (Wells, et al., 2011; Turkyilmaz et al., 2015; Verhagen & Van Dolen, 2011; Liu et al., 2013; Wu et al., 2016 among others).

Urge to buy, positive and negative affect significantly influence online impulse buying. The results of present study confirm the finding of (Verhagen and van Dolen, 2011). Sales promotion came out to be an important factor to enhance online IBB as consumers buy goods spontaneously with immediate effect from sales promotion. The results disclose that sales promotion has a positive relationship with OIBB; the results of this study are similar with findings from (Badgaiyan et al., 2015; Hultén and Vanyushyn, 2014; Lo Yi-shih, 2016 among others). This study further found that sales promotion, as active moderator, strongly influences the relationship between website quality and OIBB. Developing influential online sales promotion is highly advised for e retailers in China. Use of credit card facilitates the consumers to buy goods immediately. This study reported that use of credit card positively and significantly influences the online impulse purchases. Our findings are also supported by previously conducted studies (e.g., Badgaiyan and Verma, 2015; Roberts & Jones, 2001; Karbasivar & yarahmadi, 2011 among others). In china, customers are encouraged to buy products through credit card and third party payments over cash. Moreover, results indicate that use of credit card significantly moderates the relationship between website quality and online impulse purchases.

Realizing the steep increase in trend of buying online, present study has explored the role of website quality in triggering online impulse buying behavior. Main thesis of research was to analyze above

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

stated relationship after augmenting with sales promotion and use of credit card as moderators in model. Study was conducted in China, world's leading emerging economy, having largest number of netizens and online shoppers. Previously conducted studies on said purpose have lacked of sales promotion and use of credit card as moderators for impulse buying behavior from the defined drivers. Present research has employed well-established SEM after conducted reliability and validity tests to validate the scale.

Generally, the proposed theoretical model was well supported empirically. At first, study presented a higher proportion (more than 90%) of online shoppers in China. Study is concluded by following major findings; OIBB is influenced by website quality at large scale; sales promotions and use of credit cards are found to be efficient triggering elements to enhance OIBB. Empirical analysis lead us to conclude that effect of website quality becomes robust when it is supplemented with sales promotion and use of credit card as moderators. Further, present study presents the clear conclusion that online shopping portals can influence the credit card holder visitors' consciousness to buy impulsively when websites exhibit higher quality features accompanying by sales promotion strategies.

Implications

Previous researches on online impulse buying have not described clearly how website quality, sales promotion, use of credit card, positive and negative effects of emotion and urge to buy affect online impulse buying behavior. The present study gives an integrated approach to examine the impact of website quality, sales promotion, use of credit card, positive and negative affect and urge to buy on online impulse buying in the context of Chinese e-commerce environment. The findings of this study contain both theoretical and practical implications. All factors of this study show significant impact on OIBB in either an individual or an integrated approach. The effect of website quality on OIBB in Chinese e-commence setting is the new knowledge added in the field of e-commerce. Although some previously established studies have analyzed the role of sales promotion and credit card in offline impulse buying setting, identifying their role as moderators is still needed. Moreover, online buying is replacing the trend of offline shopping. Findings added new knowledge in the body of e-marketing and e-retailing. In summary, this study has strengthened the theoretical knowledge in the field of e-commerce and related literature by identifying a gap between previous studies.

Significant practical implications are also found from the results. The attributes of website quality facilitate the consumers spending more time on web browsing. Therefore, online retailers should recognize the importance of website related attributes in online store. Online retailers need to improve web design (user friendly, visual appealing, enhance product category with attractive, rich information about products, minimum response time and build trust) in order to increase the impulse buying. Online retailers may provoke the impulsive buying by refining the attributes of website and their retail performance. Specifically, they should focus on user-friendly interface strategy for motivating the impulsive consumers in creating their own product searching process conveniently. Online retailers should design a flexible navigating featured website by providing a rich product category with attractive variety and add visually appealing factors related with their products, such as fonts, colors, graphics and appetitive picture for eatables. Online retail managers should focus on the contents of the web stores with regard to providing enough information about their products and provide big variety of products category comparatively their competitors for encouraging the online shoppers to buy impulsively. Finally, online retail managers who wish to enhance the impulsive consumer should achieve high profit by improving their website attributes and services.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The primary guideline obtained from the study is that the firms trading in hedonic products should provoke the effects of positive emotions rather than diminishing its negative effects. Online retailers should create positive emotions by making shopping encounters excitement, inspiring and enthusiastic; this phenomenon leads towards impulsive buying. Sales promotion positively affects online impulse buying, e-tail managers should design different promotional strategies (e.g., discounted price, cross selling and up selling) on their website for encouraging the impulsive shoppers. They can create specific web page and links for promotional products for visitors. Finally, they are advised to develop their promotional policy differently for heavy and normal users for motivating them. Use of credit plays a significant moderating role between website quality and online impulse shoppers. Chinese e-tail managers can provide different payment method with regard to target audience. They should facilitate to their impulsive consumers in terms of providing the facility of credit card payment. In order to encourage the impulsive buyers, they should device strategies offering discounts to customers based upon frequency of their buying. Providing the facility of credit card is not enough because privacy and security concerns are there. Online retail firms should design a fully protected system integrated with third party like banks to create the shoppers' trust. Findings are helpful for the e-retailers (e.g., Jd.com, taobao.com, amazon.cn, tmal.com, vip.com, bj.jumei.com, dangdang.com, gome.com, suning.com, etc.) that are operating in China. Although study was conducted in Chinese context, implications are not limited to China only and can be extended to other cultural contexts and regions.

Limitations and Future Opportunities

This manuscript has identified some significant understandings about online impulse buying, but still there are some limitations. Convenient sampling was used for this study; other sampling technique (e.g. quota sampling, stratified sampling and simple random sampling) may produce some more valuable insights. The current study was carried out in two big cities of china; future researches may be conducted in smaller cities and results can be compared subsequently. This study employs only cross sectional estimation techniques. Respondents of our study were mainly females. This may raise concerns about evenly gender distribution biasness in study finding. However, women are more likely to shop online and this fact validates our findings.

This research can be extended with additional factors such as personal traits, cultural and situational factors to understand online IBB. Some technology based conception such like success model and flow experience (Wu et al., 2016) can be used as alternatives to extend the present study. Future scholars can use technology based theory e.g., technology acceptance model (TAM) and other important theories e.g. cognitive emotion theory, prospect theory, reactance theory, reflective-impulsive model and S-O-R frame work. Finally, study can report different results if it is conducted exclusively on big shopping Chinese festivals (e.g., 6.18 6 June, Double Eleven and Double Twelve). Social commerce platforms can also be targeted for future endeavors because they have different features as compared to shopping websites (Xiang et al., 2016; Chen et al., 2016).

Chapter 8
Influences and Intention of Consumer's Online Shopping Decision: Jordan as a Case

Radwan Moh'd Al-Dwairi
Department of MIS, Faculty of Information Technology and Computer Sciences, Yarmouk University, Irbid, Jordan

Murad Al Azzam
Department of MIS, Faculty of Information Technology and Computer Sciences, Yarmouk University, Irbid, Jordan

Abstract

Many researchers in Jordan tried to study customers' behavior in the domain of online shopping to understand consumers' attitudes and behaviors towards the adoption process. Still, a lot of work is to be done as customers real usage and adoption level is low which entails more research to be done to investigate the main reasons behind such behavior. In response, this article aims to shed light on consumers' attitudes towards online shopping decisions and extends the technology acceptance model ease of use, perceived usefulness) of the technology acceptance model (TAM) with four factors (trust, security, privacy, and risk). As such, 200 undergraduate and postgraduate students from Yarmouk University formulate the sample of this study. Findings indicate that the six factors are significantly impact consumers' intention to adopt online shopping. Additionally, the F-test of this study indicates that a linear relationship exists between the model's variables and consequently they can be utilized to study this process.

INTRODUCTION

Online shopping has been usually accepted as a mean of buying products and services. It has grown to be a new accepted means in the Internet world (Bourlakis, Papagiannidis & Fox, 2008). In addition, it

provides consumers additional information and selections to evaluate price and product, more selection, easier to locate everything online (Butler & Peppard, 1998). There are several explanations why people go online for shopping. For instances, customers be able to buy products at any time instead of going to the physical market; they can locate the similar product or service with low price through comparing multi websites at one time and customers want to keep away from traffics.

These factors could be categorized into three categories: efficiency of cost and time (Prasad & Aryasri, 2009), product and information availability (Lim and Dubinsky, 2004), convenience (Wang, 2005), and disintermediation (Gupta, 2014) in which suppliers and buyers interact with each other without intermediaries which achieves a good level of transparency. As a result of that all information about products and services is in the hands of customers. In this environment, many factors are considered important in the eyes of consumes when they intend to adopt electronic commerce transactions. Some of these factors are related to the website and its content like accuracy, usefulness, usability and quality (Huang & Benyoucef, 2013; Al-Dwairi & Kamala, 2010; Al-Dwairi & Kamala, 2009) whereas some other factors are related and perceived by the consumer like trust, risk, security and privacy (Kim, Ferrin & Rao, 2008; Al-Dwairi & Kamala, 2009).

Under the umbrella of e-commerce, many applications like e-learning, e-government, online banking, e-payments, online shopping, etc. are exist (Turban, King & Lang, 2011, p. 51). Online shopping is performed according to the availability of electronic means in which information and service could be exchanged electronically. Online shopping is conducted based on web technology like e-commerce web sites and communication tools such as internet as a transformation channel (Galant, Jakubczyc & Paprzycki, 2002). The diffusion of online shopping as a modern approach in customers' daily life changes consumer lifestyle and accelerates the way consumers transfer their services online. Internet shopping as new business model uses web technology that enables companies to have a competitive advantage and good return when it is used properly (Al-Madi, Al-Zawahreh & Al-Qawasmi, 2013). In addition, customers' satisfaction will increase when they decide to use online shopping instead of conventional shopping due to savings in time, efforts, and money (Andersone & Sarkane, 2015). Yannopoulos (2011) pointed that buyers can benefit from online shopping by entering to worldwide e-markets anytime and anywhere with new chances for fast search, comparing prices and getting special offers. In addition, sellers can benefit by accessing international markets and increasing their revenues and earnings.

The extensive use of internet and web 2.0 increased the experience of people in using new ICT tools and push them to conduct online shopping transactions. As a result of that, the rate of using internet shopping transactions is increasing rapidly. Dabrowski & Acton (2013) mentioned that there was a quick growth in online shopping where it exceeded $279 billion in 2015. In addition, the wide spread and use of social media enable consumers to share and post products and services information over the web. Consequently, customers are able to make good relations and collaborate easily with firms, which in turn boost the level of trust between them which finally leads to increase customer's intention to adopt online shopping (Zhang, Cheung & Lee, 2014).

Jordan as a small country in the Middle East has enhanced and improved the use of information and communication technologies (ICT) and web 2.0 tools to enhance the way of life for people who live in Jordan. For example, the use of e-government facilities to provide Jordanian citizens with online services will increase e-participations and enhance the spread of utilizing online business transactions (Abu-Shanab & Khasawneh, 2013). Despite the high penetration rate of ICT tools among Jordanians and the good knowledge and experience in using computers and internet websites, yet traditional shopping still the dominant (Al-Madi et al., 2013). Based on this, customers' intentions and behaviors to adopt online

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

shopping is not clear which calls for more research in this field. In response this study offers a real opportunity to close this gap by conducting a study to investigate the main factors that affect customers' adoption of online shopping in Jordan.

LITERATURE REVIEW

Al-Jabari, Othman and Mat (2012) examined the factors that promote the formation of the actual online shopping behavior among Jordanian customers. The findings of their study pointed that subjective norm and perceived behavioral control have significant positive effects on Jordanians intention to shop online. In addition, attitude showed no direct significant impact on online shopping intention. Halaweh (2011) focused on the security challenge in the online shopping environment in Jordan from a customer and an organizational perspective. The study recommends that this factor is important and should be considered from online marketers.

Alsmadi (2002) conducted study to investigate the factors that affect consumers' attitudes towards online shopping in Jordan. Results of his study showed that Jordanians have good skills and knowledge to use online shopping but they are doubt about the security measures of online transactions. Hence, security is a major factor that restricts customer's willingness to make a better use of online shopping. Altarifi, Al-Hawary and Al Sakkal (2015) conducted an empirical study to examine electronic commerce drivers and their impact on customers' online purchasing decisions. Their findings showed that cultural and technological factors had significant influence on consumer buying decision. Their study recommends to deploy some strategies to protect the Internet as a medium of transactions and to conduct intensive awareness programs to encourage consumers to use online shopping services. Al-Azzam & Mahmoud (2014) proposed and implemented a framework to understand Jordanian Youth attitudes towards online shopping and their intention to shop online. The results of their study revealed that perceived ease of use; perceived behavioral control, attitude, and perceived usefulness are important antecedents in determining online customers behavior. However, the study found no significant impact of trust on online purchasing behavior. Nuseir, Arora, Al-Masri and Gharaibeh (2010) examined a proposed model to test the effect of e-commerce web site presentation on online shopping customers and discovered that promotion security were the most influential factors on consumer purchase intentions. In addition, the Internet infrastructure and product and service characteristics had moderately impacted the consumers' decision process.

On the other side, many scholars have proposed conceptual models and conducted variety empirical studies in the developing countries aiming to shed light on consumers' behaviors towards online shopping. For example, Al-Salamin & Al-Hammad (2015) presented a study of measuring the attitude of Saudi consumers towards online shopping. The study pointed that company risk, financial risk, and privacy are significant factors that affect consumer's intention to use online shopping. In addition, the study pointed that the technical infrastructure is not sufficient to offer the required security measures for online transactions. Alemu, Bandyopadhyay and Negash (2015) investigated ATM customers' opinions towards technology adoption in Ethiopia and found that women perceived themselves to be more susceptible to fraud and other security risks.

AlGhamdi, Nguyen, Nguyen and Drew (2012) conducted a research to identify and discover key issues that positively or negatively influence Saudi retailers towards the adoption of the online shopping. Their research showed that the most important inhibitors of online shopping are habits of people in Saudi

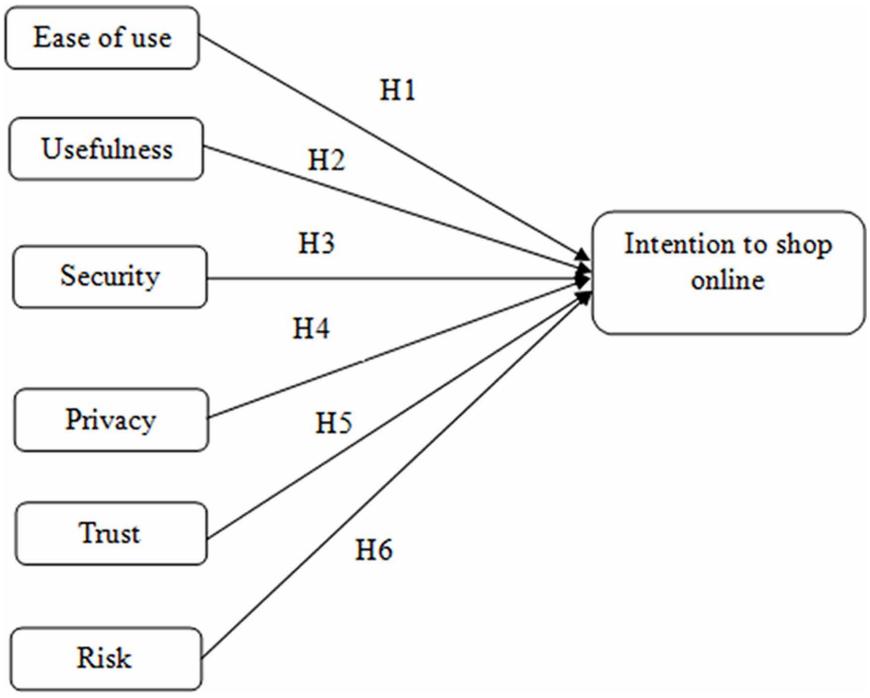
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Arabia, lack of clear legislations and rules of e-commerce, and lack of online shopping experience. Liat & Wuan (2014) conducted a research in Malaysia in a trial to understand consumers' intentions towards online shopping by examining the impact of some factors on intention. Findings of their research have discovered that trust, perceived usefulness and subjective norm are the most significant factors on online purchase intention. However, perceived ease of use and perceived enjoyment are not significantly impacted consumers intentions. Stephens & McGowan (2015) suggested a model to compare the students' convenience perceptions between who is purchasing books online and who is purchasing books using the traditional method. Results of their study validated the SERVCON model in the e-service environment. Zeba & Ganguli (2016) conducted an empirical study to test the impact of Word-of-mouth, trust, and Perceived risk on online shopping by proposing a model based on TAM. Their findings showed a positive Would-of-Mouth and perceived risk significantly impacted online purchase intention.

RESEARCH MODEL AND HYPOTHESES DEVELOPMENT

Figure 1 depicts the conceptual design for the proposed model. This model is proposed based on the Technology Acceptance Model (TAM) (Davis, 1989). Rigopoulos et al. (2008) argued that TAM has been extensively deployed as a tool to measure users' attitudes towards technology adoption like online shopping. In essence, many scholars were used TAM to investigate and predict user's acceptance of information technology (Taylor & Todd, 1995; Gefen & Straub, 2003). In addition to the two factors of TAM (perceived ease of use [PEOU] and Perceived usefulness [PU]), our model incorporated four independent variables (Perceived security, Perceived privacy, Perceived trust, and Perceived risk) and one dependent variable (online shopping intention to use) as shown in Figure 1.

Figure 1. The research model



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Ease of Use

Davis (1989) defined PEOU as the degree to which the user expects the system to be used with no difficulties or with less effort. Amaro & Duarte (2015) mentioned that technologies that are supposed to be easier to use and not difficult have a greater opportunity of acceptance and use by consumers. Online shopping uses ICT tools, therefore, the good application and interface which are easy to use will affect consumer's intention to use online shopping (Chiu, Wang, Fang & Huang, 2014; Al-Dwairi, 2013; Fang & Huang, 2014). Based on this, the following hypothesis can be addressed:

H1: Perceived ease of use has a significant positive impact on consumer's intention to use online shopping.

Usefulness

Davis (1989) defined PU as the degree to which using of particular information technology will increase the user's performance. Consumer's performance of using online shopping depends on how much users can benefit from buying their needs online. Rose & Dhandayudham (2014) pointed that the usefulness of online shopping depends on the characteristics of the products and how they are useful for users. If consumers feel that such products or services are useful, then the usefulness is achieved, consequently consumers' intention to use online shopping will be increased (Bagdoniene & Zemblyte, 2009; Zaidi, Gondal, Yasmin, Rizwan & Urooj, 2015). Based on this, the following hypothesis can be addressed:

H2: Perceived usefulness has a significant positive impact on consumer's intention to use online shopping.

Security

Consumers usually are aware about their personal and financial information. Therefore, they pay more attention to use online shopping if they feel that their online transactions and their personal data is safe (Akbar & James, 2013; Al-Dwairi, 2013). Security and fulfillment are important in the intention to use online shopping. Therefore, providing accurate information about security and the payment type give good motivation to users to use online shopping. Moreover, e-retailers must give accurate information about products, services, and payments (Lu, Chang & Yu, 2013). Any weaknesses in the security measures of e-commerce systems will put consumers under risk. Consequently, their financial and personal information might be misused by external parties (Bagdoniene & Zemblyte, 2009). Based on this, the following hypothesis can be addressed:

H3: Perceived security has a significant positive impact on consumer's intention to use online shopping.

Privacy

In order to proceed with online shopping transactions, consumers should reveal their personal and financial information to merchant's web sites. In this environment, customers' lack of familiarity with merchants makes consumers reluctant to reveal their information to online shopping web sites. Providing high security measures and assurances from merchants about consumer's personal and financial information

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

will help consumers to proceed with their online transactions (Al-Khasawneh, 2014; Ariff, Sylvester, Zakuan, Ismail & Ali, 2014; Al-Dwairi, 2013). Based on this, the following hypothesis can be addressed:

H4: High privacy measures have a significant positive impact on consumer's intention to use online shopping.

Risk

Perceived risk is well-defined as the possibility for loss in the environment of online shopping. In this vein, it is obvious that risk is a major factor that negatively impacted consumer's intention towards online shopping. Consumers usually expose to some level of risk. Such a matter is established because consumers should deal with digital companies using the Internet. As a result of that, consumers are uncertain about the actions and promises fulfillment of digital firms (Kim et al., 2008) and the possibility of hacking. Based on this, the following hypothesis can be addressed:

H5: Perceived risk has a significant negative impact on consumer's intention to use online shopping.

Trust

Trust is concerned as one of most important factors that affect use and adoption of online shopping; it is mainly concerned with a consumer's belief about the purchased product or service that is ordered via the Web whether is it meets user's expectation or not (Kim et al, 2008). People who are intended to adopt the online shopping may have low trust in such means of shopping since they don't have the ability to touch or recognize the products which are presented via the web site (Al-Dwairi & Kamala, 2009). This generates a lack of trust for consumers which ultimately could affect their intention to use the online shopping. As a result of that, trust is a crucial factor that encourages consumers to take a decision to shop online in a risky environment. Based on this, the following hypothesis can be addressed:

H6: Perceived trust has a significant positive impact on consumer's intention to use online shopping.

RESEARCH METHODOLOGY

The Instrument and the Sample of the Study

The main aim of this research is to focus on Jordanian behavior toward the online shopping by investigating the expected drivers that affect consumers' intentions and final decisions to use online shopping. To this end, a quantitative approach is utilized by collecting data utilizing university students as they are young, educated and use this type of technology. The survey questionnaire was developed based the previous literature.

Questions of the perceived ease of use and perceived usefulness were adapted from Sentosa & Mat (2012). Questions of the security item were adapted from (Abu-Shanab & Al-Azzam, 2013). Privacy questions were adapted from Masoud (2013). Risk questions were adapted from (Abu-Shanab & Al-Azzam, 2013; Abu-Shanab, 2014). Trust questions from (Masoud, 2013) and intention's questions adapted from

Table 1. Demographic profile

variable	category	Response information N (198)
gender	male female	54 (27.3%) 144(72.7%)
age	less than 25 25-45 46-60	174 (87.9%) 23 (11.6%) 1 (0.5%)
education	diploma bachelor master	4 (2%) 182 91.9%) 12 (6.1%)
Total		198 (100%)

(Sentosa & Mat, 2012). A 5-point Likert scale was used for measuring the variables with 1 = Strongly Disagree; 2 = Disagree; 3 = Neutral; 4 = Agree; 5 = Strongly Agree. In this study 200 undergraduate and postgraduate students were selected randomly. Outlier analysis is a measure that is used to check if some data in the collected dataset significantly different from the remaining data. Hair, Jr., J. F., Black, W. C., Babin, B. J., Anderson, R. E., and Tatham, R. L., (2006) pointed that outliers should be removed from the dataset because they can affect the research results. The SPSS software automatically deleted two outlier records. As a result of that, the final sample size that is used for analysis is 198. The sample demographics are shown in Table 1.

Reliability Analysis

Cronbach's alpha (Cronbach, 1951) was used to estimate the internal consistency for the items of the study. This measure is known as coefficient alpha which widely used as a measure of reliability. It measures how well a set of factors describe a single latent construct. The recommended value of this measure is to be above 0.80 while the lowest value is 0.70. In some cases, 0.60 could be acceptable (Hair et al., 2006). Table 2 shows the reliability values of the items of the study.

Table 2. Individual items reliability

Construct	Cronbach's Alpha	Number of items
PEOU	0.759	3
PU	0.794	4
Trust	0.616	4
Security	0.744	5
Privacy	0.841	5
Risk	0.621	4
ITU	0.889	3
All Constructs	0.814	28

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

RESEARCH RESULTS

Analysis of the collected data was performed using via descriptive statistics, correlation, and multiple linear regression tests. Mean values analysis show how respondents in the study perceived the constructs of the study or the proposed model. Hence, this test gives an indication about the importance of the used constructs. Table 3 shows the mean values of the study constructs. According to Abu-Shanab (2014) mean values are considered high if the exceeds 3.67 out of 5 and moderate if the mean values are from 2.33 to 3.57. Based on this, perceived ease of use construct is highly perceived by online shoppers. In addition, perceived usefulness, trust, security, privacy and risk have a moderate consideration by customers.

Table 3. Mean values of the constructs

	N	Mean
PEOU	198	3.8670
PU	198	3.6692
TRUST	198	3.1667
SEC	198	2.9967
PRIV	198	3.1023
RISK	198	3.2879
ITU	198	3.3047
Valid N (listwise)	198	

In addition to the mean test, Pearson correlation is used in this study to examine the strength of the associations that exist between the factors of this study. A rule of thumb is to consider the correlation value as weak from 0 up to 0.29, medium from 0.30 – 0.49, and strong if its values are 0.50 or more. Multicollinearity can be observed when two or more constructs in the proposed model are correlated with a redundant correlation value that exceeds (0.9). In this study, the correlation matrix that is presented in Table 4 shows no redundant correlation. Hence, the problem of multicollinearity does not exist. In addition, the multi-collinearity for the proposed model as shown in Table 4 was checked and found that variance inflation factors were below the acceptable threshold which are less than 10 (Kennedy, 2003).

Table 4. Coefficients

Model		Collinearity Statistics	
		Tolerance	VIF
1	PEOU	.866	1.155
	PU	.846	1.182
	Trust	.980	1.020
	Security	.910	1.099
	Privacy	.875	1.142
	Risk	.966	1.035
a. Dependent Variable: ITU			

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The correlation values that exist between respondents' perceived ease of use, perceived usefulness, trust, privacy, security, and intention to shop online are all significant. However, the correlation between risk and intention to shop online is not significant. This means that the impact of risk in comparison with the other factors on intention is low. The correlation between risk and trust is negative. The correlation value reflects the negative impact of risk on trust. Table 5 shows the correlation matrix for the variables of the study.

Table 5. Items correlation matrix

		PEOU	PU	Trust	Security	Privacy	Risk	ITU
PEOU	Pearson Correlation	1						
	Sig. (2-tailed)							
PU	Pearson Correlation	.349**	1					
	Sig. (2-tailed)	.000						
Trust	Pearson Correlation	.015	-.043-	1				
	Sig. (2-tailed)	.835	.546					
Security	Pearson Correlation	.042	.174**	.134	1			
	Sig. (2-tailed)	.555	.014	.060				
Privacy	Pearson Correlation	.251**	.296**	.089	.523**	1		
	Sig. (2-tailed)	.000	.000	.212	.000			
Risk	Pearson Correlation	.111	.128	-.035-	.003	.101	1	
	Sig. (2-tailed)	.118	.072	.627	.965	.156		
ITU	Pearson Correlation	.294**	.363**	.419**	.366**	.434**	.163**	1
	Sig. (2-tailed)	.000	.000	.000	.000	.000	.021	

**. Correlation is significant at the 0.01 level (2-tailed).

Multiple regression analysis was utilized to answer the related hypotheses. Hair et al. (2006) defined regression analysis as a statistical technique which is used to analyze the association between more than one independent variables and one dependent variable. According to Asfour & Haddad (2014), the value of R^2 depicts the strength of the relationship that exists between the dependent and independent variables. Table 6 shows R2 Model's summary.

Table 6. Multiple linear model summary

Model Summary[b]					
Model		**R**	**R Square**	**Adjusted R Square**	**Std. Error of the Estimate**
dimension0	1	**0.673**[a]	0.452	0.435	0.43118

a. Predictors: (Constant), PEOU, PU, Trust, Privacy, Security, Risk

b. Dependent Variable: ITU

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 7. ANOVA[b]

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	29.328	6	4.888	26.292	.000[a]
	Residual	35.510	192	.186		
	Total	64.838	198			

a. Predictors: (Constant),), PEOU, PU, Trust, Privacy, Security, Risk

b. Dependent Variable: ITU

As shown in Table 6 and 7, the results indicate a significant prediction level, where the six constructs explained 67.3% of the variance of students' intention to use online shopping. The F test ($F6,192 = 26.292$, $p < 0.001$) indicates that the proposed model is fit and powerful in explaining such value of variance.

Table 8. Multiple regression analysis-coefficient results

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Result
		B	Std. Error	Beta			
1	(Constant)	-.066-	.292		-.227-	.821	
	PEOU	.084	.036	.138	2.361	.019	significant
	PU	.146	.038	.230	3.887	.000	significant
	TRUST	.473	.066	.391	7.198	.000	significant
	SECURITY	.116	.045	.163	2.560	.011	significant
	PRIVACY	.128	.042	.200	3.008	.003	significant
	RISK	.082	.040	.112	2.053	.041	significant

a. Dependent Variable: ITU

Results that are presented in Table 8 show that the P values of PEOU, PU, PU security, privacy, trust, and risk are less than 0.05 which, means that hypotheses H1, H2, H3, H4, H5, and H6 are all supported. The above table shows a two-sided p values. In this study, the relationship that exists between dependent variable (Intention to shop online) and every independent variable (PEOU, PU, trust, security, privacy, and risk) is one side relationship. The one-tail P value is half the two-tail P value.

DISCUSSION AND RESEARCH IMPLICATIONS

Online shopping is conceptualized as a process that ultimately leads a consumer to decide whether to buy or not based on a particular behavior. In essence, such behavior can be studied from different points of view. As such, many factors can contribute in establishing a positive or negative behavior towards the usage of this new technology (Davis, 1989). Past studies broadly focused on many factors like web page design, security, risk, trust, etc. This study offers a good opportunity to shed light over such factors by studying its impact on the intention and behaviors of Jordanian consumers. The purpose of this

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

empirical study is to investigate the reality of online shopping adoption in Jordan and determine the main drivers that contribute in shaping a consumer's positive behavior towards the usage of this new business channel. Indeed, this will lead us to expose to various limitations and barriers of adopting this new business model.

Findings of the study indicated that Jordanians decisions and intentions towards the usage of online shopping are affected by the ease of use of online shopping technology. This means that Jordanian consumers have a positive behavior regarding the adoption on using online shopping as they found it to be easy to use and does not need a big effort to accomplish the tasks of such process (sig. value of PEOU= 0095 < P= 0.05). This finding is in line with (Al-Azzam & Mahmoud, 2014, Al-Dwairi & Kamala 2009), Al-Dwairi, 2013). Additionally, if consumers perceive that using online shopping can increase their performance by getting many benefits like saving time and money; then they will have a positive behavior and intention to use the online shopping. In this study Jordanian consumers found that they can achieve many benefits like saving their time, money, and efforts by using the online shopping. Also, the Web offers a competitive environment to consumers to purchase items with low prices and having special offers. Hence consumers' performance is increased (sig. value of PU= 0.000, < P= 0.05). This finding is in line with (Al-Azzam & Mahmoud, 2014, Al-Dwairi & Kamala 2009, Al-Dwairi, 2013).

In addition, findings of the study indicated that Perceived security has a significant impact on Jordanian consumers ' intention to adopt online shopping (sig. value of Security= 0.0.005, < P= 0.05). As a result, Jordanian respondents feel that the security measures which are offered by the Internet and the digital companies are sufficient and safe enough and positively impacted their intentions to proceed with their online transactions. Additionally, consumers are ready to use the online shopping Web sites' that are endorsed with security seals. As a result of that, their online transactions, personnel, and financial data cannot be exposed. Thus, Jordanian consumers "perceived security" has a significant effect on their future decisions to use online shopping. These findings are matches the findings of (Halaweh, 2011, Nuseir et al., 2010, Alsmadi, 2002).

In order to proceed with online transactions, consumers should disclose their personal and financial information to the digital companies. As a result of that, consumers may be become more reluctant to reveal such sensitive data to commercial Web sites because their privacy may be misused. Findings of this study show that Jordanians are aware about their privacy (sig. value of privacy = 0.0015, < P= 0.05). This indicated that privacy of online consumers has played a significant role in impacting their intention toward online shopping. This finding matches the findings of (Al-Khasawneh, 2014; Ariff et al., 2014; Al-Dwairi, 2013).

In this research, perceived risk is the possibility of loss in the domain of online shopping. Hence, it is obvious that risk is a major factor that negatively impacted consumer's intention towards online shopping. Findings of this study show that Jordanian consumers are aware about the possibility of being under many kinds of threat or risks and agreed about its negative impact on their intention to shop online (sig. value of PU= 0.0205 < P= 0.05). For example, consumers are aware about their credit card information. In addition, consumers are not able to check and test the purchased items during the online purchasing process. So that consumers have a concern about the quality of the shipped items. In this critical situation, the role of consumers' trust raise as a moderated factor which bridge the gap between risk and consumers intention to proceed with consumers' online transactions in risky situations. Findings of this research revealed that consumers trust has a significant impact toward their final decisions (sig. value of PU= 0.000, < P= 0.05). This result agree with the findings of (Liat & Wuan, 2014; Al-Dwairi, 2013).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

This research has many implications. Firstly, this study can be considered as one of the important studies that focuses on the importance of deploying information technology in providing customers with variety of e-services like online shopping and e-tailing. Findings of this study highlight the significant role of technology acceptance in the adoption of online shopping. Indeed, results imply that TAM with its salient factors (PEOU & PU) is still used as one of the main theories which gage user's acceptance of a particular technology and its significant impact on the adoption of that technology. As such, Jordanian consumers will be able to adopt online shopping if it is easy to use and offer good benefits for them. This finding also implies that IT developers should design high quality e-commerce web sites that achieve the requirements of TAM to increase consumers' online shopping adoption level. Second, the findings of this study value the significant role of security and privacy factors in adopting online shopping. As a result of that, digital companies should deploy the latest technology standards to protect consumers' personnel and financial data as well as online transactions by using strong cryptographic protocols and sealing their Web sites with security seals. This will boost consumers' impression about the security measures that are used in such e-commerce Web sites. Finally, results imply that telecommunication companies should continue enhancing their networks and the related infrastructure which is needful to offer more Web services to Jordanian consumers.

LIMITATIONS AND FUTURE RESEARCH

This study is restricted by some limitations. For example, the sample of this study has been taken from Yarmouk University students which may affect the generalizability of the results. In addition to this, the proposed model can be extended with more factors that are related to the consumer as a human who will ultimately decide to proceed with the online transaction or not based on a formulated behavior. Taking such limitations into account motivate us to do some future research to fill such gaps. For example, utilizing the Web based questionnaire may be a good mean to allow different types of consumers in different locations and cities in Jordan to participate in such research which enrich the sample with more opinions and enlarge the sample of our future study to bridge the problem of generalizability of the results.

Moreover, extending the proposed model to check the impact of consumers demographic factors like age, gender, education, and income on intention to adopt online shopping will offer valuable opportunity to have a look at the adoption process from different points of view and may draw a big picture for Jordanian's adoption behaviour.

CONCLUSION

This study offered a true opportunity to study and investigate consumer's behavior towards the use of online shopping in Jordan by validating and testing a conceptual model. The study model extends TAM with some factors utilized from the domain of this field. 200 undergraduate and postgraduate students formulate the sample of this study. The findings of this study show a strong support for the proposed model. Additionally, the F-test is highly significant which means that the selected factors of the proposed model have a linear relationship and can successfully gauge such phenomenon.

University Institute of Technology, India

ABSTRACT

This chapter provides an overview of the e-commerce business model, the history of e-commerce, the scope of e-commerce, the difference between e-commerce and traditional commerce, issues related to e-commerce, electronic data interchange, value chain, and supply chain, and the pros and cons and limitations of e-commerce.

INTRODUCTION: E-COMMERCE

E-commerce is made of two word electronic and commerce:

- **Electronic:** Means of electronic in term of e-commerce is doing any activity (related to business, marketing, payment, communication) online.
- **Commerce:** Commerce is a branch of business. it is concerned to buying or selling of products and goods. It includes all those activities, which directly or indirectly related to business. An interchange of goods or commodities between different nations or between areas of the same nation (Hanson & Kalyanam,2009).

In this way we can say E-commerce is shifting or changing the way of doing business. It is a dot com revolution. It transfers all the business activity over the internet. so, today e-commerce is changing the way of human life. E-commerce takes place between organization, between organization and customers, or between organization and public administrative. This concept shown in Figure 1.

There are several definition of electronic commerce. Some of them are.

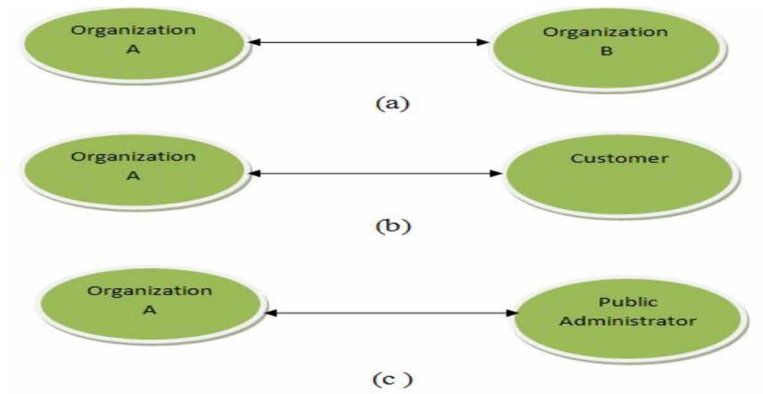
Figure 1. A transaction (a) Between organization (b) Between organization and company (c) Between organization and public administrator



According to world trade organization – " The Production, distribution, marketing, sales or delivery of goods and services by electronics means".

Kalakota and Whintons defined the term E-commerce from different perspectives. These perspectives are:

- Communication
- Business Process
- Service
- Online
- **Communication Perspective:** According to this perspective, E-commerce is the delivery of information, product/services or payments over tele-communication channels, computer networks or any other electronic mode of communication.
- **Business Process Perspective:** This says that E-commerce is the application of technology towards the automation of business transactions and work flow.
- **Service Perspective:** E-commerce is defines as a tool that addresses the desire of firms, consumers and management to cut service cost while improving the quality of goods/services and increasing the speed of service delivery.
- **Online Perspective:** Electronic commerce provide opportunity of buying and selling products and information on the internet and other online services.

According to Lou Gerstner, IBM's CEO, "E-commerce is all about time cycle, speed, globalization, enhanced productivity, reaching new customers, and sharing knowledge across institutions for competitive advantage." Zwass (1996) defines e-commerce as:

The sharing of business information, maintaining business relationships, and the conducting business transactions by means of telecommunications networks.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

HISTORY OF E-COMMERCE

In 1970 introduce a term electronic fund transfer, whereby funds could be transfer or routed electronically from one company to another company. Generally these application was used only few organization like banks, large corporations. In banks are electronic transmission of account exchange information over private networks. After some year electronic data interchange occur when one business transmit computer readable data in standard format to another business. It means sending business documents such as purchase order and invoice electronically (Schneide P.G.,2007).

The standard formats used in EDI contain the same information that business have always included in their standard paper invoices, purchase order and shipping documents. Some farms such as general electric(GE) and wal-mart have been pioneer in using EDI to improve their purchasing process and their suppliers. One major problem with EDI faced is the high cost of implementation because it used private or value added network. A VAN is an independent firm that after connection and transaction forwarding services to buyers and seller engaged in EDI. When the internet become commercialized and users began to participate in the world wide web. In early 1990, the term electronic commerce was introduced. A large number of dot coms or internet based business started rapidly. One reason for this rapid expansion was the development of new networks, protocol and electronic commerce software. The other reason was increase in competition and other business pressures (Dennis P.,2004).

In starting year of 1995, most of medium and large size organization in world has a web site. Many of these web sites contain thousand of page and links. In 1999, the emphasis of electronic commerce shifted from B2C to B2B and in 2001 from B2B to B2E, e-government, e-learning, M-commerce.

Scope of Electronic Commerce

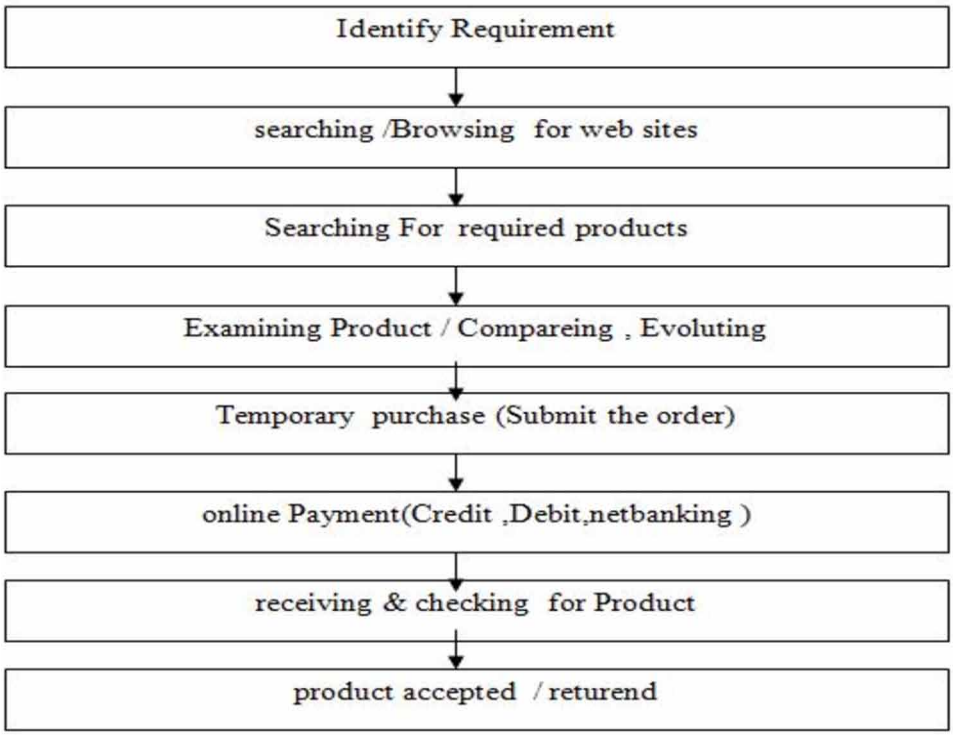
There are some main areas where scope of E-commerce. These are:

- EDI on the Internet
- Exchange of digitized information
- Direct marketing, selling and service.
- Online banking and billing.
- Secure distribution of data.
- Shopping on the World Wide Web.
- Product sales and services on the web.

In E -Commerce there are some steps for purchasing the products and take some services from the e- commerce, starting from the requirement identification, searching the web sites for purchasing, and then analyzing that product then place it for payment and complete this cycle of purchasing by receiving the product shown in Figure 2.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Process flow in e-commerce



Differences Between Electronic Commerce and Traditional Commerce

Face to Face Interaction

Traditional commerce based on face to face interaction. the consumer has a chance to ask questions frequently and satisfy before purchasing a product. On the other hand, E-commerce doesn't based on face to face interaction.

Real Estate Cost

Traditional commerce relies on physical store space that needs to be rented. It is too much costly while e-commerce there is no cost for real estate.

Reach

With an online shop you can do business with anybody living on a country you are able and willing to send mail to, unlike traditional commerce where you are restricted to people who actually come to your shop. This also opens the door to many other forms of marketing that can be done entirely online, which often results in a much larger volume of sales and even foot traffic to the store. An online store has no capability limits, and you can have as many clients as your stock can serve.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Returns Rate

In a traditional store, the customer will be purchasing the product in person, which has some benefits for both the him and the store. The customer will be able to touch and check the items, to make sure they are suitable, and even try them on, which reduces the number of returned items or complaints due to an item not being as advertised on a catalogue. or promotional leaflet. Expect a significantly higher rate of returns if you start trading online, as many will just order and try the items at home, and won't hesitate to return them as they can do it by post without having to talk with anybody in person (Greenstein & Feinman, 2001).

Credit Card Fraud

The remote nature of E-commerce makes much more difficult to detect fraud, which means stores can lose money due to fraud. While traditional commerce is not totally secure, it's easier for a sales attendant to verify that the person buying something is actually the owner of the credit card, by asking for photographic ID. However, the fight against card fraud is well underway and banks and responsible e-Commerce owners work together to verify that all card use is legitimate.

Availability

E-commerce based online store available for purchasing any item every time. It means you can do business 24/7. In Traditional commerce do not provide such type of facility.

E-COMMERCE ARCHİTECTURE

E-commerce is based on the client –server architecture. A client can act as an application, which follows a Graphical User Interface (GUI) for sending request to server for certain services. The server is used to provide the services upon the request of client. In E-commerce, a client refers to a customer that sends a requests to a server for a service then that request is further transferred to business applications which helps in providing the service. The business application is mainly dependent on Web Server. Web server is a program that deliver services to other computer programs and serves the Hyper Text Mark-up Language pages or files. In client server architecture, a machine behave like client and a server. There are two types of client-server architecture: Two – Tier and Three-Tier.

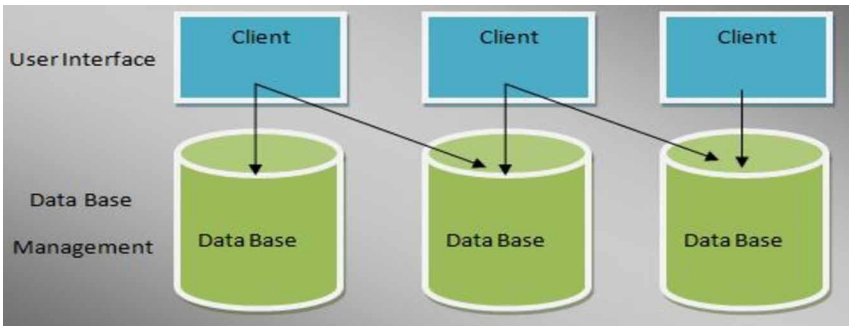
Two –Tier Architecture

In two tier architecture there is two level that is presentation layer and data layer.

The client handles the user interface part and provide an interface for the customer that gather and present the data on the computer of customer. This part of application is known as presentation layer. The application logic can be run on the client or the server. It allows the separation of client processes from server processes on different computer. The database is stored on the server. This part of application is known as data layer. The data validation, monitors security permissions and performs other business rules done by business logic can be kept on the client or the server.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Two –tier architecture



Three-Tier Architecture

This architecture emerged in 1990's to overcome the limitation of two tier .In three tier there is an independent module for user interface and business application logic. The three tier include the three tier: top tier, middle tier and third tier.

The top tier acts as a presentation layer which provides services as session, text input, dialog and display management reside.

The middle tier provides services of process management such as process development, process resourcing and process monitoring that are shared by multiple applications. It also has centralized process logic which makes administration easier by localizing the system functionality.

The third tier provides database management functionality. The component ensures that data is consistent throughout the environment.

Figure 4. Three –tier architecture

TYPES OF E-COMMERCE MODEL

There are four major segments under the category of e-commerce model. These are:

- Business to business e-commerce (B2B).
- Business to consumers e-commerce (B2C).
- Consumers to consumers e-commerce (C2C).
- Consumer to business e-commerce (C2B).

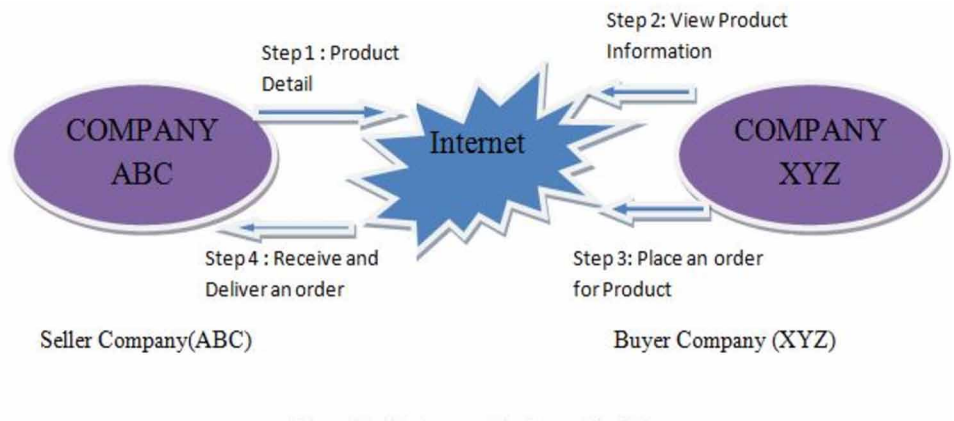
Business to Business (B2B)

Business-to-business implies the selling of products and services between corporations and the automation of systems via integration. This category of commerce typically involves suppliers, distributors, manufacturers, stores, etc. On the other hand The B2B model involves electronic transactions for ordering, purchasing, as well as other administrative tasks between organizations. It includes trading goods, such as business subscriptions, professional services, manufacturing, and wholesale dealings. Sometimes in the B2B model, business may exist between virtual companies, neither of which may have any physical existence. In such cases, business is conducted only through the Internet (Rajaraman V.2009).

Let us look at the same example of amazon.com . As you know, amazon.com is an online bookstore that sells books form various publishers including TMH, PHI, O'Reilly, Wrox, and so on. In this case, the publishers have the option of either developing their own site or displaying their books on the amazon site, or both. The publishers mainly choose to display their books on amazon at it gives them a larger audience. Now, to do this, the publishers need to transact with amazon, involving business houses on both the ends, is the B2B model.

Consider a hypothetical example. ABC company sells electronic parts and XYZ company assembles these part and then sells the electronic item to customers. XYZ company comes across the web site of ABC and finds it suitable. XYZ company, requests for more information about ABC and finally, decides to purchase electronic parts from ABC. To do this, XYZ places an order on the web site of ABC. After ABC receives the order details, it validates the information. As soon as the order is confirmed, the pay-

Figure 5. Business to Business Model



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ment procedures are settled. Finally, ABC sends an acknowledgement of payment to XYZ and delivers the goods as per the shipment details decided between the two organizations. Figure 5 show Business to Business Model.

Majorly there are four step involve when one business communicate to another Business. These are:

Step 1: Seller Company make a website and display all the product detail. For example electronic company give detail all the product related to all electronic product.

Step 2: Buyer Company view a product and find a information about the product on a seller company website.

Step 3: Buyer Company place a order to seller company over the internet for assembling a product. For example buyer company make Laptop or computer, so it place order like electronic circuit, SMPS, Fan, motherboard, processor, hard disk etc.

Step 4: Receive a order from buyer company and the settlement of payment between seller and buyer company. Seller Company delivers a product to the buyer company.

Business to Consumers E-Commerce

When a consumer purchase a product form a e-store over the internet and fully transaction is carried out electronically, we call it business to consumer e-commerce or business to consumer e-commerce. Business to consumer involves interaction and transaction between a business and its end consumer and so it create electronic storefronts that offer information, services, product between business and consumer in a retailing transaction. It applies to any business organization that sells its products or services to consumers over the Internet. These sites display product information in an online catalog and store it in a database. The B2C model also includes services online banking, travel services, and health information. Business to consumer model include virtual malls, which are website, host may placed order online virtual malls (Joseph P.T. & S.J.,2009).

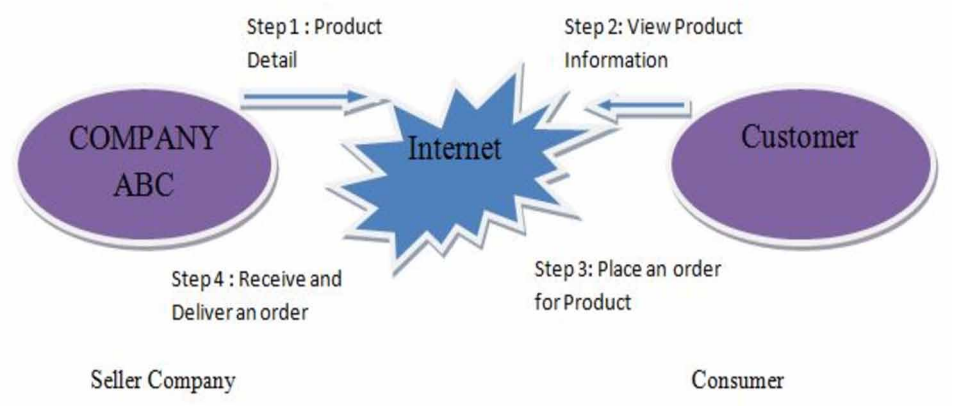
Consider a hypothetical example in which a transaction is conducted between a business Company and a consumer. A Company, XYZ Department Store, displays and sells a range of products on their Web site, www.xyz.com. The details information of all their products is contained in the huge catalogs maintained by xyz Department Stores. Now, a consumer, ABC wants to buy a gift for his wife. He therefore, logs on to the site of XYZ Department Stores and selects a gift from the catalog. He also gets the detailed information about the gift such as, the price, availability, discounts, and so on from their catalog. Finally, when he decides to buy the gift, he places an order for the gift on their Web site. To place an order, he needs to specify his personal and credit card information on xyz company. This information is then validated by XYZ Department Store and stored in their database. On verification of the information the order is processed. Therefore, as you can see, the B2C model involves transactions between a consumer an done or more business organizations. Figure 6 show Business to consumer model.

Majorly there are four step involve between business and customer transaction. These are:

Step 1: Seller Company make a website and display all the product detail. Details information of all their products is contained in the huge catalogs maintained by Company Store. For example electronic company give detail all the product related to all electronic product i.e cost, availability, discount, technical feature of product .

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Business to Consumer Model



Step 2: Customer view a product and find and analysis a information about the product on a seller company website.

Step 3: Customer place a order to seller company over the internet. For example purchase Laptop or computer, so it place order to seller company.

Step 4: Receive a order and payment from customer. Seller Company delivers a product to customer.

The example of the amazon site also involves the B2C model in which the consumer searches for a book on their site and places an order, if required. This implies that a complete business solution might be an integration solution of more than one business model. For example, amazon includes the B2B model in which the publishers transact with amazon and the B2C model in which an individual consumer transact with the business organization.

Table 1. Difference between B2B and B2C model

Subject	B2B	B2C
Commerce Activity	Transaction between Organization	Transaction between organization and company
Business Models	The business models in B2B are much more defensible than in B2C. In B2B, buyers and suppliers are made more efficient, competitive and profitable.	The B2C models are based on optimizing the ability to directly attract, manage and support the individual customer, thus eliminating the traditional middleman.
Order size	Order size is large	Order size is small
Customer Relationships	Relationships are much more complex, long-term, often contractual and involve bigger dollar amount. They involve intricate procurement models, supply chain automation, engineering and planning collaboration.	B2C relationships are usually one-sided, where businesses define and control the relationship with the consumer.
Example	SalesForce,Ripple,Replyup	Apple, Microsoft, Ebay, Walmart, Disney, Coca-Cola,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The B2C model of e-commerce is more prone to the security threats because individual consumers provide their credit card and personal information on the web site of a business organization. In addition, the consumer might doubt that his information is secured and used effectively by the business organization. This is the main reason why the B2C model is not very widely accepted. Therefore, it becomes very essential for the business organizations to provide robust security mechanisms that can guarantee a consumer for securing his information.

Customer to Business Model (C2B)

The C2B model involves a transaction that is conducted between a consumer and a business organization. It is similar to the B2C model, however, the difference is that in this case the consumer is the seller and the business organization is the buyer. In this kind of a transaction, the consumers decide the price of a particular product rather than the supplier. This category includes individuals who sell products and services to organizations (Wbiteley D.,2005). For example, monster.com, naukari.com is a job related Web site on which a consumer can post his bio-data for the services he can offer. Any business organization that is interested in deploying the services of the consumer can contact him and then employ him, if suitable .

Majorly there are five step involve between customer and business transaction. These are:

Step 1: Post the product or information on the portal. This portal manages by third company not related to seller and buyer. This company provide a facility to seller consumer and Buyer Company make a business.

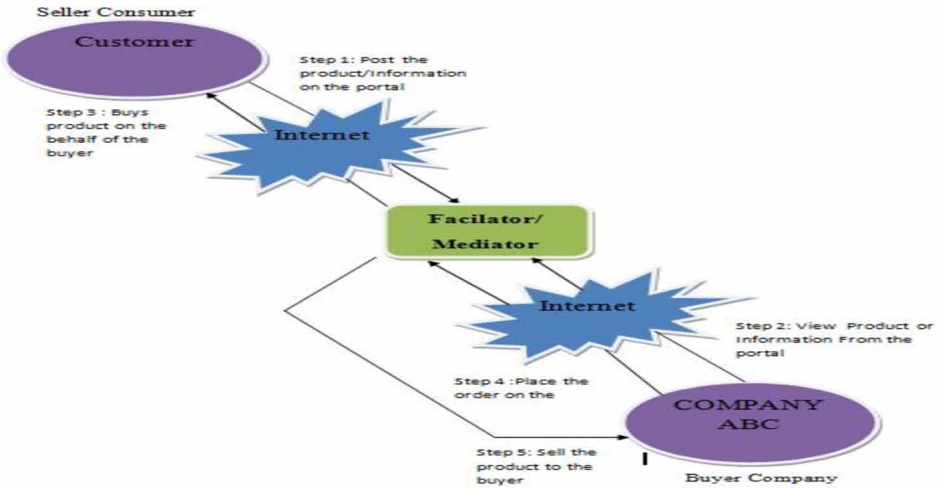
Step 2: Buyer company view a product or information from the portal.

Step 3: After analysis a product or information, buyer company place a order on portal.

Step 4: Facilator or mediator Company give a information to seller, buyer company purchase your product or information.

Step 5: Consumer give a confirmation to Facilator or mediator company. This company sell a product or information to the buyer company.

Figure 7. Consumer to Business Model



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Let us look at another example of the C2B model. Rohan needs to buy an airline ticket for his journey from New Delhi to Bombay. Rohan needs to travel immediately. Therefore, he searches a Web site for a ticket. The Web site offers bidding facility to people who want to buy tickets immediately. On the Web site, Rohan quotes the highest price and gets the ticket.

Customer to Customer Model

The C2C model involves transaction between consumers. Here, a consumer sells directly to another consumer. eBay, QUCKIER and OLX, are common examples of online auction Web sites that provide a consumer to advertise and sell their products online to another consumer. However, it is essential that both the seller and the buyer must register with the auction site. While the seller needs to pay a fixed fee to the online auction house to sell their products, the buyer can bid without paying any fee. The site brings the buyer and seller together to conduct deals (Chan H. et al, 2008).

Let us now look at the previous figure with respect to eBay. When a customer plans to sell his products to other customers on the Web site of eBay, he first needs to interact with an eBay site, which in this case acts as a facilitator of the overall transaction. Then, the seller can host his product on www.ebay.com, which in turn charges him for this. Any buyer can now browse the site of eBay to search for the product he interested in. If the buyer comes across such a product, he places an order for the same on the Web site of eBay. eBay now purchase the product from the seller and then, sells it to the buyer. In this way, though the transaction is between two customers, an organization acts as an interface between the two organizations. Figure 8 shows a Consumer to Consumer Model.

Majorly there are five step involve between customer and customer transaction. These are:

Step 1: Post the product or information on the portal. This portal manages by third company not related to seller consumer and buyer consumer. This company provide a facility to seller consumer and Buyer consumer make a business.

Step 2: Buyer Consumer view a product or information from the portal.

Figure 8. Consumer to Consumer Model

Table 2. Difference between C2B and C2C

Subject	C2B	C2C
Commerce Activity	transaction between consumer and business organization	transaction between consumers
Business Models	In this case the consumer is the seller and the business organization is the buyer. consumers decide the price of a particular product rather than the supplier	a consumer sells directly to another consumer
Example	monster.com, naukari.com	eBay, QUCKIER and OLX

Step 3: After analysis a product or information, buyer consumer place a order on portal.

Step 4: Facilator or mediator Company give a information to seller Consumer, a buyer consumer purchase your product or information.

Step 5: Seller consumer give a confirmation to Facilator or mediator company. This company sell a product or information to the buyer consumer.

ADVANTAGES AND DISADVANTAGES

Proper implementation of E-commerce can increase the sell of business. Every technology have own advantage or disadvantage. Some of them are.

Advantages

Business is Open 24 x 7 x 364 7/8

We can also sell any time, night or day, 365 days a year. Even while we are resting, it works while you play or sleep. They are open for business every hour of the day, every day of the week, every week of the year.

Choice of Product

Electronic commerce provides buyers with a wider range of choices than traditional commerce.

Tax Benefit for Government

Electronic payments can be easier to monitor than payments are made by cheques/cash. All the transaction online so it is benefit for government and there are no chances of stealing a tax.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Worldwide Market Space

Advertising on the web can make a big or small firm's promotional message reach out to potential customers all over the world quickly and small cost as an online marketing strategy.

Decrease Transaction Costs

If we buy from online store, we spend low operational cost, we have better quality of service, and we can cut the many unnecessary costs. For example, if our goods or services downloadable, we will have transport costs completely cancel.

Conduct a Business Easily

In electronic commerce, we do not need to physical company setups or there are not any crowds to deal with. We can buy from our house comfortable; users can easily choose goods from various procedures without moving around physically.

Comparison in Prices

Everyone can easily compare fees among the various web sites. We can usually earn discounts on fees when compared with normal shop fees.

The Decrease of the Functioning Costs

These costs may be drastically diminished by the automatics of the orders process. There is also the possibility of a total automatics by the integration with the administration system thus leading to the increase of the general productivity of the company.

International Markets Penetration Facilities

The world network is not limited by borders, it does not belong to anyone and the access and publication costs are extremely low. The communication with a customer positioned to the opposite pole of the world is as easy as the communication with someone in the next room. Any producer now can sell his products in any country by the means of the web site and no contacts with local companies or large investments are necessary anymore(Lawrence E., 2000).

Disadvantages

The Security

Security is a main problem in electronic commerce. Everyone good or bad can easily open a web site, and there are many bad sites, which their aim is fool user's and earn money (Kalakota R. & Andrew B. Whinston,1997).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Guarantee

There is no guarantee for product quality. Our orders might be damage in the post or things may look different online to what you actually receive for example, slightly different colours and feel of clothes or the freshness of vegetables and fruits.

Social Relationships

Electronic commerce allows to users that buying and selling goods and services without geographic limitations but in this method we have not any contacts and relationships with other persons and loss our social contacts.

Inability to Feel the Physical

It is nearly impossible to sell things like furniture and tires online. Furniture is something people like to sit on and know the feel. Tires need to be installed once purchased. The old tires also need to be disposed of. In both instances, there is a need for real actions to fulfil the reason for the purchase. That's why things like food, jewellery, antiques etc. can never turn to E-commerce.

Economics

In industry world, managers must encourage and conduct employees to devise plans to take advantages of new economic opportunities. Electronic commerce is creating new opportunities to the global economic, for example in global travel and tourism industry. Transforming from traditional business method to electronic commerce method is hard and there were many different factors for companies to adapt them with electronic commerce factors. For this work, they must used Internet and many other online networks, because for grow and use from new economic opportunities in each industry it is necessary to be match with new technologies.

FINANCE AND ACCOUNTING

Two decades of progress in information technology and development of its applications in the field of economic and social to form a new chapter of relations between people, institutions, companies and governments and new concepts are emerging on literature of economic and trade. Internet as a global network, as well as prerequisite of electronic commerce, for reason flexibility, attractive, ease for use, low cost access and ubiquity, is changing the traditional business moreover, electronic commerce had a significant impact on finance and accounting that include saving time, disinflation, increase productivity, reduce the demand for money (reduce the cost of publishing) and etc.

Limitations

There are some barriers for electronic commerce setup, which include:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Lack of knowledge and necessary information for use of electronic commerce and Internet network.
- Protection of consumer rights in electronic commerce.
- Lack of legal infrastructures in electronic commerce such documents that are not acceptable and electronic signature.
- Low security of electronic funds transfer in some countries.
- Lower speed and limitations on the use of Internet.
- Lack of information intermediary institutions and manufacturing companies of the benefits of Internet business.
- The security and confidentiality of information exchanged.

Case Study on Online Marketing (Amazon)

In 1994 when Amazon was launched it just a small book store and now that become a big name in e-commerce world. In USA, it is the top online retailer, helps for distribution of all products and services. Its popularity has aroused a question as how it has become popular and the answer is its effective business policies and marketing plans.

So the purpose of this case study is to discuss the ideas that lies behind the successful business of the Amazon. So the ideas are:

1. **Name Selection:** At initial stages the name of the company was "Cadabra" which is more similar to abracadabra. The owner of the company "Jeff Bezos" changed its name to "Amazon" to make it unique. The reason behind that was as "A" is the first alphabetical letter among other 26 letters. Secondly, The name depicts a biggest river "Amazon" like that he wants to make his store a bigger store. In an interview "Jeff Bezos" said, "There's nothing about our model that can't be copied over time. But you know, McDonald's got copied. And it still built a huge, multibillion-dollar company. A lot of it comes down to the brand name. Brand names are more important online than they are in the physical world."
2. **Product Planning Should be Best:** In a report it has been stated that in future e commerce will develop upto 2300%. Jeff Bezos at that time selected a list of product to be put online for sell. He narrowed these upto 20 products and later upto 5 books, videos, computer software, hardware, and compact discs and then at last selected Books. Their result of good planning and innovative thinking was achieved in first two months with sales rise upto $20,000/week.
3. **Logo Name:** After 2000, Amazon has changed his logo with a curve showing a smile sign and an arrow from A to Z, it means that Amazon has all a to z products in its store. This make its logo unique(Amazon Web Services, n.d.).
4. **Initial Growth:** During earlier phases of Amazon was bit slow and its stockholders thought that this will bring less profit in the future .In 2001, it has started gaining profit. The strong business plan that helped in survival from dot-com bubble.
5. **Partnerships:** The company has done different partnerships with types of companies like ToysRus, Borders bookstores, Marks & Spencer, Mothercare, and Lacoste etc. which helped in the stability.
6. **Expansion of Business:** The company is now focused on the expansion of services. In this respect, Amazon has started its store in 2014 in India. Along with it it is also focused on the festival season by giving their services like Diwali Dhamaka Week sale that helped in its popularity.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

7. **Membership:** The membership program has started in which the members are paying $79 per month .The features provided is the purchased product will be delivered within two days with some discount. Another membership benefits are free access to instant videos streaming and TV shows, Kindle Owners' Lending Library.
8. **Consumer Services and Use of Technology:** The main focus is on providing best services to their customers. In regards to that for e book readers, the Amazon Kindle was introduced in 2007, for book download and then reading through proper display. Amazon has introduced its tablet computer series followed by second generation tablet in 2011 along with other products such as Fire TV and smart phone.
9. **Separate Website for Each Country:** Each country has different preference and prospective so Amazon has a separate website for each country like:
    a. amazon.in for India
    b. amazon.fr for France
    c. amazon.de for Germany
    d. amazon.it for Italy
10. **Third Party Selling:** Along with the items that are available in store, Amazon provides an opportunity to other store to sell their products. The product must be unique. This also provides opportunity for other businesses and the biggest source of profit for the Amazon. There are about 900,000 members' with their product available on Amazon.

What Amazon Is Doing Right That Others Are Not?

E-commerce website involve many element. Even the smaller detail can make a huge impact. With the increase in competition user experience has been playing an important role. If user experience has not good then they will switch on to other site. Digital user experience is the experience a user undergoes, while he is searching for company product until making a payment. For any website to stand in the competition the focus will be on user experience and maximization of information about the product. The Amazon focuses heavily on the points such a s Customer Delight & Experience, Technology, Metrics and Analytics, Complete focus on customer experience even at a low cost of margins. Amazon has innovated a lot in terms of technology, products, services and marketing. Here are some live case examples:

1. **Amazon's Login Page:** Sign in -If you see closely Amazon uses "Sign in using our secure server" button for Login rather than just using "sign in" text on the button. They are reinforcing that sign in process is secure and safe to grab a user's attention.
2. **Product Pages:** In the product pages, they provide maximum details by using same product name as that of title and same name in the meta description along with product code.
3. **FAQ's Section:** has been started where customers can put up their queries for their response. Users can also search if his question has already been asked and answered; if not then the user can post a question for the response. There also an option of up vote and down vote the answer to signify that whether you were satisfied with the response. Almost all products has FAQs this helps the users in a great way as their doubts are answered which increases the chances of a purchase from consumer.
4. **Mail Tracking:** Track package details in Email: Amazon is one of the few E-Commerce companies which uses email schema markup to the fullest. So when user orders something, an email is sent

Figure 9. FAQ's section

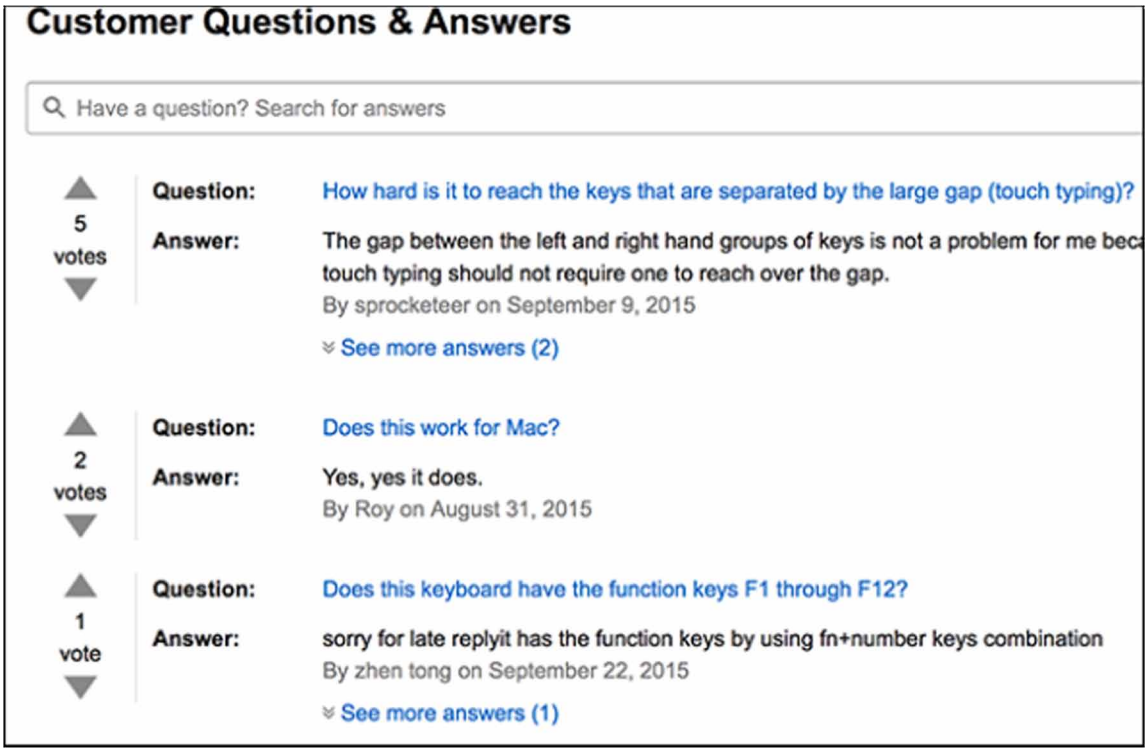

Figure 10. Mail tracking

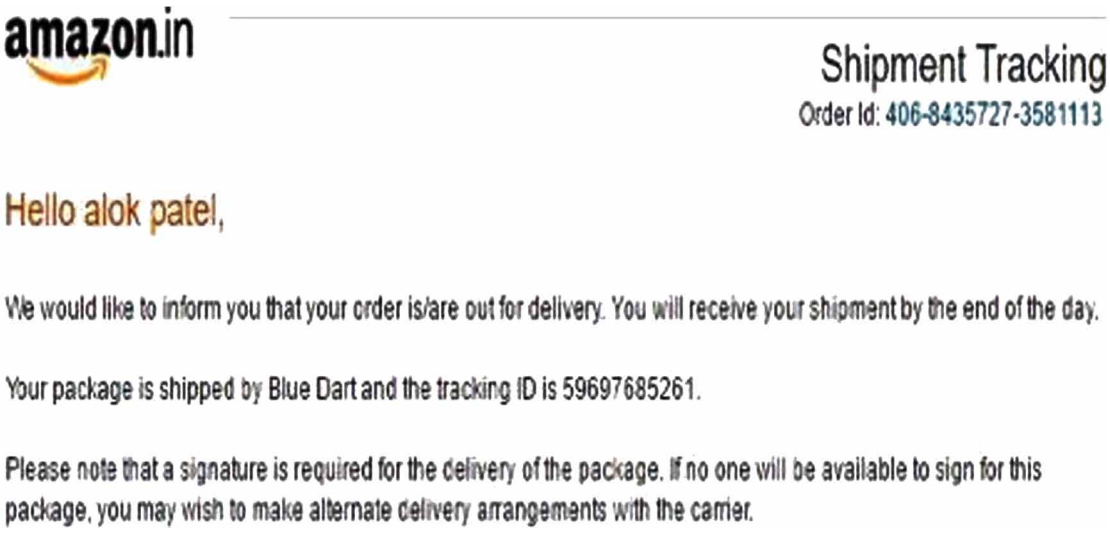

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

to the customer telling about the details about the order and the delivery stage along with a link to see the status of delivery. The email schema is also provided in which they do not have to open the email.

5. **Amazon Customer Care:** Amazon does have significant customer base and sometimes these customers wants to connect with the customer care of Amazon. Many customer search google so as to reduce the effort of the customer, Amazon uses schema markup to let search engines know what their customer care number is. The searching for customer care for service oriented company has lot of search traffic.
6. **Amazon Device Adaptability:** Amazon.in site has device adaptability for all most browsers. It supports right from IE6 to latest IE, Chrome, Mozilla. if you see flipkart.com, it doesn't support any browsers less than IE7.

What to Learn?

Every person who want to make their business successful can adapt the following things:

- Unique and Planned selection of name .
- Planning of product should be long term. The products which are frequent should be sold which is a long term planning.
- A logo with a small graphic through which whole business can be explained .
- Don't be afraid of failures, work hard till success.
- Partnerships helps in popularity so on share basis do partnership.
- Focus the expansion in one country then take it to another slowly.
- Offer various services like membership packages for the customers and give them promising advantage so that they start trusting you.
- High speed technology to add latest features will help in gaining popularity.
- Depending on the places make separate websites so that preference should be clear. Personalization of Website should be done according to the preferences.
- Give opportunity to others after you have become stable.

SUMMARY

All the above ideas are implemented by Amazon. So, you can adopt these ideas without any worry.

There are different types of web sites on the World Wide Web for various types of services or transaction.

CONCLUSION

E-commerce has now become a key component for many organizations for daily running their business. In actually E-commerce is buying and selling of goods on the internet known as E-Business, making a lot of opportunities for profit and advancements for businesses, whereas making a lot of choices for shoppers. However, similar to anything, e-commerce has its disadvantages as well as client uncertainties, however, nothing which will not be resolved or avoided by smart decision-making and business practices.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

There are many factors associated variables that require to be thought of and set upon once beginning an e-commerce business. A number of these include: kinds of e-commerce, selling ways, and myriad a lot of. If the right strategies and practices are followed, a business can prosper in associate e-commerce setting with abundant success and profit.

Chapter 10
Strategizing SCM-M Interface Using DeLone and McLean Model of IS Success and Fuzzy Cognitive Maps:
Perspectives on E-Commerce Success

Shekhar Shukla
S.P. Jain Institute of Management and Research, Mumbai, India

B.K. Mohanty
IIM Lucknow, Uttar Pradesh, India

Ashwani Kumar

ABSTRACT

The article presents a unique approach to explore and evaluate the critical factors of supply chain management-marketing (SCM-M) interfaces in e-commerce. This article systematically identifies the critical factors of SCM-M interface in e-commerce using DeLone and McLean (D&M) Model of IS Success. The critical factors identified are used to form the dynamic scenarios based on Fuzzy Cognitive Maps (FCM) for strategizing the e-commerce success. To understand and evaluate the proposed research methodology, some scenarios were developed based on the critical factors of SCM-M interface in e-commerce. The analysis of these scenarios aid in identifying the improvement areas as well as strategizing and improving those areas of SCM-M interface in e-commerce for enhanced customer satisfaction and leveraging organizational success.

INTRODUCTION

According to Forbes (Forbes, 2014), Walmart stands at the top in terms of its sales and as the 18th most valuable brand. This success of Walmart is often attributed to its highly efficient Supply Chain Management (SCM) and marketing integration (Kozlenkova, Hult, Lund, Mena, & Kekec, 2015). However, its prime competitor K-mart has struggled financially over the last few decades which is mostly attributed to its weak congruence of SCM and marketing practices (Bogenrief, 2012). In this paper, we focus on understanding the synergetic aspects of SCM and Marketing in e-commerce that act as a source of leveraging strategic and competitive benefits for firms.

An important imperative of Marketing is to deliver values like customer satisfaction, customer support etc. to the end users. Efficient supply chains allow firms to pass along benefits like optimized costs, timely delivery etc. to the end users; thus, generating an increased value for these customers (Kozlenkova et al., 2015). This makes the role of SCM very important and at the very core of Marketing Success.

On the other hand, success of SCM relies on both intra and inter organizational relationships. Logistics, Purchase, Operations and Marketing Channels broadly form the functional domains of SCM. Marketing Channels form the last fragment of SCM but are very important in determining the needs of the end customer for whom the entire supply chain is co-ordinated and adjusted as required. Thus, using Market Research for collecting valuable information of environment, competitors, customers, suppliers etc. can help in better implementation of SCM (Min & Mentzer, 2000). This makes Marketing very impactful in determining the success of SCM.

SCM-Marketing (SCM-M) are very closely linked processes and concepts intertwined with each other. Thus, it has become immensely important to harness the benefits of SCM-M interface. This synergetic value of SCM-M interface has also been identified and applauded in several research works (Ellinger, 2000; Martin & Grbac, 2003; Min & Mentzer, 2000; Svensson, 2002). Esper (Esper, Ellinger, Stank, Flint, & Moon, 2010) highlight the fact that a focus on individualistic SCM or Marketing domain and negligence of SCM-M interface often leads to suboptimal benefits for the firms. Noci (Noci, 2019) in his work provides a deep insight to how business processes and organizational changes be directed to harness the utility of SCM-M interface. Copley (Copley, 2018) demonstrates the experiential learning in an entrepreneurial setting for practical benefits of SCM-M interface. SCM-M coordination (Samatli-Pac, Shen, & Hu, 2018) has also been studied from the point of view of loss aversion, customer utility and reverse logistics. Some other research works (Flint, 2004; Piercy, 2008) identify the potential of synergies of SCM-M interface in providing competitive advantage.

However, in the changing dynamics of global business environment (from traditional to digital); customers no longer simply plan for and shop at the nearest retailer; rather they pick up the nearest digital device. Neilson (Neilson, 2012) cited in its report that online retail sales through e-commerce would double between 2015 and 2019. E-commerce has created a revolution in global businesses by increased customer base, streamlined Supply Chains, enhanced customer value, increased profits, reduced costs and entry in the new markets (Karavdic & Gregory, 2005).

Thus, it is important to study the impact of strategizing SCM-M interface for E-commerce success which is one of the important and transformational means of business. Lee and Wang (Lee & Whang, 2001) in their work identified, that e-businesses/e-commerce have a humungous potential to reap benefits of SCM-M interface. They mention that e-businesses can integrate SCM empowered with the factors of Information Integration, Planning Synchronization, Workflow Coordination and Alternate Business Models. This will drive better marketing intelligence in terms of utilizing data sources captured through

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

online transactions and interactions to make marketing decisions like Assortment, Pricing, Promotional Offers, and Demand Estimation etc. The scientific methods based on statistical analysis, optimization, business intelligence etc. can help for the cause. Avlonitis and Karayanni (Avlonitis & Karayanni, 2000) also mention the scope that e-commerce has in utilizing synergies of SCM and Marketing for added customer services and enhanced customer relationship. Ardito et al. (Ardito, Petruzzelli, Panniello, & Garavelli, 2018) highlighted the role of advanced technologies to support SCM-M integration from the view point of information processing. IoT based technological innovation (Chkoniya & Mateus, 2019) are also explored to understand a better demand and supply side collaboration and automation.

The humungous investments and revenue of firms from e-commerce has attracted researchers and practitioners to increase the efficacy of these systems and evaluate their Information System (IS) success (DeLone & Mclean, 2004). Keen (Keen, 1980) highlighted in his noted work Management Information System Research that it is important to measure the "effectiveness" or "success" of IS to encourage firms for investments in technology. Information System success evaluates the ease of creation, distribution and usage of information enabled with technology. However, there is an uncertainty on which factors to be considered best for measuring the IS success of systems (Rai, Lang, & Welker, 2002).

DeLone and McLean (DeLone & McLean, 1992) initially came up with an IS success model which was open to validation and development. Several researchers came up with their re-specification and validation of this model (McGill, Hobbs, & Klobas, 2003; Molla & Licker, 2001; Rai et al., 2002; Seddon & Kiew, 1996) and suggested different re-specifications to DeLone and McLean (D&M) IS success model. However, a continuum of ever-increasing factors was translated into a single impact or factor or benefit category known as "Net Benefits" by DeLone and McLean (DeLone & McLean, 2003) in an updated model.

D&M IS success model that is an IS success model based on communication theory syncs well with the structural and functional aspects of e-commerce (DeLone, McLean, & others, 2016) and thus is best for identifying factors that attribute to e-commerce success. The strong theoretical similarity between e-commerce and D&M promotes us to use D&M IS success model to identify those critical factors which impact the SCM-M interface of e-commerce.

Once these critical factors of success of e-commerce from SCM-M interface are identified, they are subjected to a scenario-based analysis. Scenarios are developed primarily in situations where (Kok, 2009):

- There is uncertainty in the factors shaping the future;
- It is important to understand a long term and broad view of the possible future.

We need to model a complex situation where components are connected through chains and loops or components are a mixture of quantitative and qualitative factors. Fuzzy Cognitive Maps (FCM) can be used to model such complex situations and develop scenarios. These scenarios can encapsulate human understanding and notations due to their graphical representation and capture the vagueness or uncertainty of factors using Fuzzy Logic. Dynamic scenarios proposed by the stakeholders based on FCM help in the strategic planning of SCM-M interface for e-commerce success.

This paper aims to serve as a linkage between the theoretical and the practical aspects of harnessing benefits of SCM-M interface in e-commerce businesses. This is done by synergetic power of D&M IS success model and FCM in order to explore and evaluate planning and decisions for SCM-M interface to provide strategic advantage to e-commerce.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The results of this analysis at its face value clearly manifest at least in the following three important aspects:

- It allows a decision makers and stakeholders to express their understanding of SCM-M factors to strategize e-commerce in a qualitative fashion which is acceptable and understandable;
- It will help the decision maker model specific situations of SCM-M interface to impact e-commerce success;
- It will help he decision maker understand the impact of factors to the strategic goal as well as dynamics of these factors among themselves.

Thus, the primary research premise of the problem to identify SCM-M interface key determinants for e-commerce success provide basis for empirical research that contributes to the theory of similar academic/business research in anticipation as follows:

- This work acts as a basis for experimenting the importance of determinants of SCM-M based on scenario analysis;
- This is a new dimension to explore the avenues for empirical research incorporating both qualitative and quantitative inputs of stakeholders;
- And most importantly, this scenario-based analysis forms a strong reference for any academic or business research in terms of flexibility using Fuzzy Cognitive Maps and acceptability using D&M IS Success Model.

The rest of the paper is structured into the following sections. Next four sections present the basic ideas and concepts around the primary topics of this work like SCM-M interface, D&M IS success model and E-commerce, Critical SCM-M factors of E-commerce using D&M Model and Scenario Planning and FCM respectively. Next, we present the research methodology in a unified format. Later, we discuss an illustrative example of the Scenario-based analysis for the strategic planning of SCM-M interface in e-commerce set up and results obtained from this analysis. Finally, we present concluding remarks and some limitations and scope for future research related to our work.

SCM-M INTERFACE

Marketing is primarily concerned with effective decision making for market segmentation, targeting and positioning of products based on promotions, pricing and distribution (Kotler & Armstrong, 2007). These activities in turn are connected to creating superior customer value in terms of customer satisfaction, serviceability etc. (Kozlenkova et al., 2015). Supply chains are primarily composed of four functional units namely: Logistics, Purchase, Operations and Marketing channels where inter and intra communications among these units play a vital role for efficient SCM (Min & Mentzer, 2000). Apart from the fact that Marketing helps to provide significant information to SCM for maintaining its efficiency, specific stances of Marketing like Relationship Marketing also come in handy for effective co-operation and communication in Supply Chains (Palmatier, Scheer, Houston, Evans, & Gopalakrishna, 2007).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to PwC report (PwC, 2014), SCM and Marketing concepts and processes are intertwined with each other and act as a strategic tool in unison. Marketing creates demand for a firm's product and services and SCM helps in fulfilling that demand (Esper et al., 2010).

With the advancements like big data and concepts of just in time delivery the interplay of SCM and Marketing has become even more prominent but there is still a substantial gap in harnessing the synergies of SCM-M interface (Golgeci, Golgeci, Gligor, & Gligor, 2017). It is highly imperative for the success of firms to understand and alleviate the synergies of SCM and Marketing by bridging the disconnect between them (Juttner, Christopher, & Baker, 2007; Juttner, Christopher, & Godsell, 2010). Lee (Lee, 2001) identified some prominent dimensions on which SCM and Marketing interact and can affect business efficacy and decisions. The detrimental effect of individualistic focus on SCM leads to the problem of stock-outs and diminished service levels (Campo, Gijsbrechts, & Nisol, 2000; Emmelhainz, Stock, & Emmelhainz, 1991; Fitzsimons, 2000; Gruen & Corsten, 2007) leading to less customer satisfactions (Mollenkopf, Russo, & Frankel, 2007; Van Woensel, Van Donselaar, Broekmeulen, & Fransoo, 2007). On the other hand, if individualistic focus is on Marketing, then SCM suffers with suboptimal performance in factors like delivery time, supply chain costs and other factors that need the supply side intelligence (Day, 1994; Lamberti & Noci, 2010). Deloitte Research (Deloitte Research, 2002) in a survey conducted with 249 executives across 28 countries; found that only 17% firms have linked their SCM and Marketing domains. Another interesting outcome of this survey is the outperformance of these 17% firms, which have integrated their SCM-M domains in performance parameters like sales growth, customer satisfaction, market share etc. Another industry-wide survey of more than 800 companies (Aberdeen Group, 2008) published in their report that SCM-M interface is a strategic differentiator for firms in a variety of domains like customer service, profit making.

Further, differentiating functional aspects of an organization give rise to short term conflicts and also pose a situation of difficulty for organization to achieve its long-term goals (Stephens & Archambault, 1998).

Although the concept of integration of different functional units of organization has its roots in organizational theory and design (Galbraith, 1994; Lawrence & Lorsch, 1986; Mintzberg, 1983; Thompson, 1967, 2003), the concept has been widely used in harnessing the synergies of SCM and Marketing to possess a strategic leverage in the present scenario of fierce competitive environment among firms.

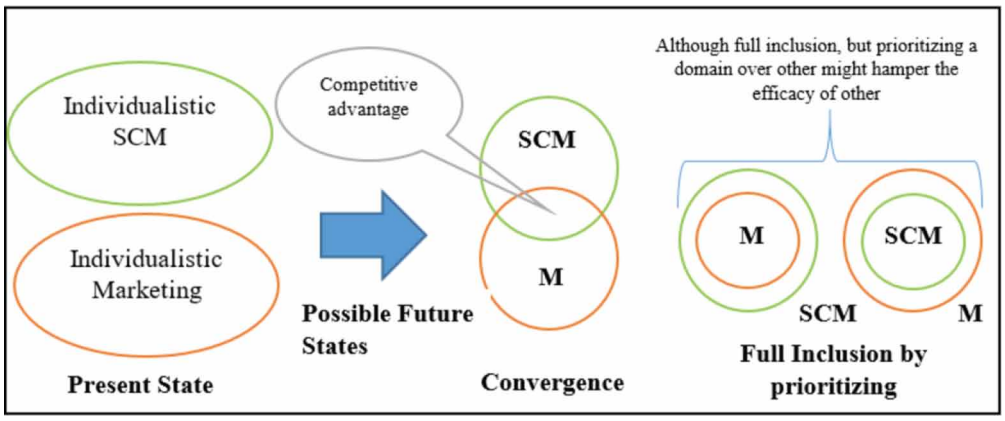
This synergetic usage of SCM-M interface to benefit businesses has been identified in several research works (Ellinger, 2000; Martin & Grbac, 2003; Min & Mentzer, 2000; Svensson, 2002). Some recent works have specifically highlighted how unique value propositions can be offered to businesses by harnessing the benefits of SCM-M interface. Sale et al (Sale, Mesak, & Inman, 2017) demonstrated an integration of New Product Marketing and Lot-Sizing Modelling of SCM to showcase the larger profits and higher market penetration pace of new product in the marketplace. Rapp (Rapp et al., 2017) provides a fresh insight on how to best meet evolving customer demands using synergies and demand and supply.

However, there is a serious lack of research concerning e-commerce and impact of synergies of SCM-M interface on it.

We present a conceptual framework of how SCM, Marketing domains should ideally move to provide a strategic advantage to firms. The present state of individualistic approach in which most firms stand need to move to a convergent approach where both domains of SCM, Marketing can together provide competitive advantage. However, prioritizing a domain and making another a subset of it by full inclusion, is also a detrimental approach, which might hamper prospects of the other domain. A flow diagram (Figure 1) showcases the present and the future desired states of SCM and Marketing Domain.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Flow diagram for expected stance of SCM, marketing domains

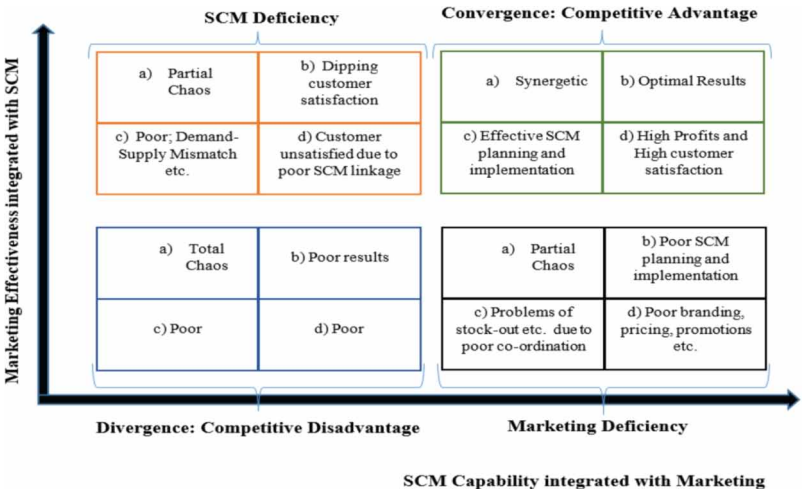


Lee (Lee, 2001; Lee & Whang, 2001) identifies SCM-M interface as the cause for competitive advantage in the 21st century for e-businesses. The work highlights the importance of how working closely with customers for demand estimation; usage of appropriate Marketing tools and providing it as an input to SCM will be a value-creating arena for firms.

We present a 2*2 matrix based conceptual framework to understand the SCM-M interface from an E-commerce perspective where each box of this matrix contains the following factors with labels as mentioned with the factors:

- **System Entropy (a):** This represents the functional coherence and stability in the organization;
- **System Value (b):** This represents the value that is offered to the end customers;
- **SCM State (c):** A measure of efficiency of SCM in the organization;
- **Marketing State (d):** A measure of effectiveness of marketing efforts in the organization.

Figure 2. Conceptual framework for SCM-M interface



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

These intrinsic factors will help in judgement of each interface in a detailed and rational way to give a clear purview of each situation.

Lee highlights the case of Volvo in 1990's. Excess inventory of green cars was cleared by marketing department through promotions, which made the production department think of high demand of these cars. They kept producing batches of these cars leading to a huge unsold inventory of green cars. On the other hand, Barilla a leading pasta manufacturer in Italy issued special discounts for customers with truckload quantities. However, supply chain costs were so high that they had to take down the special discount.

It is important to identify the parameters of demand creation like promotions, pricing, assortment etc. and next is the co-ordination of these parameters with SCM parameters like production, delivery time, and manufacturing cost etc. There is very less research that has focussed on impact of strategizing SCM-M interface on e-commerce. This understanding of SCM-M interface will help us to identify the critical SCM-M interface factors for exploring and evaluating them for e-commerce success.

DELONE AND MCLEAN MODEL OF IS SUCCESS AND E-COMMERCE

Keen (Keen, 1980) firstly questioned the lack of scientific basis for IS research and what would be the dependent variables for IS research. Since then, there is a lot of research work held in this direction. Research work on themes of technology acceptance (Davis, 1989; Davis, Bagozzi, & Warshaw, 1989), Frameworks to benefit IS systems (Kohli & Grover, 2008; Mueller, Viering, Legner, & Riempp, 2010; Peppard, Ward, & Daniel, 2007; Shang & Seddon, 2002) and assessing the business value associated with IT (Sambamurthy & Zmud, 1994; Soh & Markus, 1995) are prominently explored areas. Other prominent works in the area of determination of dependent variable for IS success is presented by DeLone and McLean (DeLone & McLean, 1992, 2003) based on Shannon and Weaver's (Shannon & Weaver, 1949) classical communication theory which was considered robust for measuring IS success. Originally, D&M IS success model came up with the following six constructs:

- System quality
- Information quality
- Use
- User satisfaction
- Individual impact and
- Organizational impact

However, the model presented was open to validation and development. Several researchers came up with their re-specification and validation of this model (McGill et al., 2003; Molla & Licker, 2001; Rai et al., 2002; Seddon & Kiew, 1996). A number of researchers suggested different re-specifications to DeLone and McLean (D&M) IS success model that can effect IS success ranging from individual, organizational, national, economic etc. factors. However, a continuum of ever-increasing factors was translated into a single impact or factor or benefits category known as "Net Benefits" by DeLone and McLean (DeLone & McLean, 2003) in an updated model with proposed enhancements to measure IS success of systems. The differentiating point between the original and updated model were primarily threefold:

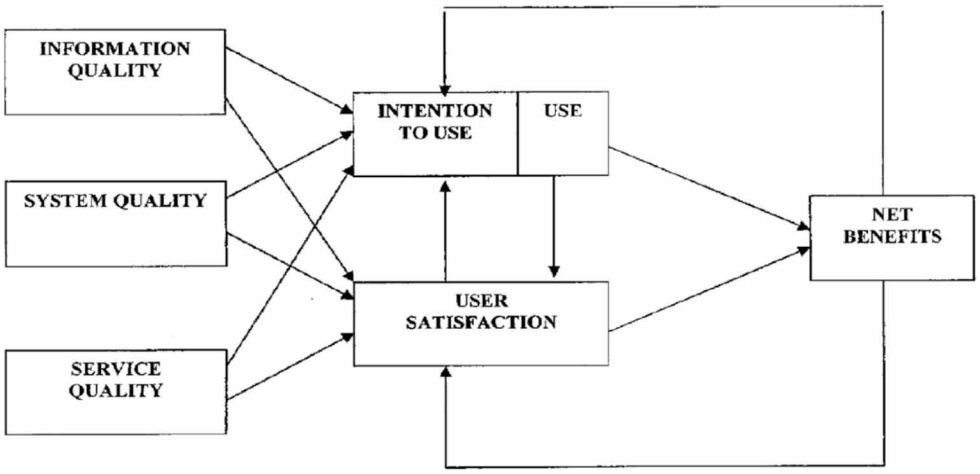
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Inclusion of concept of Service Quality to reflect the importance of parameters like customer support in the modern-day business venues like e-commerce;
2. Addition of Intention to Use as an alternative measure of use to measure he customer attitude;
3. Merging individual impact and organizational impact into a more parsimonious *Net Benefits* construct.

With above modification, the updated D&M IS success model imparts the following rationale behind its structure: Service Quality, System Quality and Information Quality of a system will affect the Intention to use or User Satisfaction. However, usage of the system will impart some Net Benefits perceived by user and will satisfy (User Satisfaction) him/her in a positive or negative way. These Net Benefits will induce Intention of Use in Users for further IS usage. Even after adding suitable modifications to original D&M IS Success model, the proposers have kept the model open for further exploration and validation.

The visual representation of updated D&M IS Success Model (DeLone & McLean, 2003) contains arrows to showcase connections among different dimensions in process sense but doesn't depict any positive or negative sign to keep the causal sense at discretion of problem situation. The following Figure 3 represents the updated D&M IS success model.

Figure 3. Updated D&M IS success model (adapted from (DeLone & McLean, 2003))



DeLone and McLean (DeLone & McLean, 2003) also explained the applicability of their proposed model in the context of e-commerce. In case of e-commerce, suppliers and customers are the primary agents who use the system to make selling or buying decisions, respectively. The transactional decisions made by these agents will eventually impact e-commerce and thus the economy at large. The applicability of e-commerce in D&M IS success model is explained below:

- **System Quality:** Measures of desired quality of an e-commerce system like usability, reliability, adaptability, response time etc.;
- **Information Quality:** Measures the content availability and security. Personalized content, easy to interpret, choosing support and security are some of the desired features;

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Service Quality:** Measures important parameters like customer support, delivery time etc.;
- **Usage:** Measures everything from visit to website, navigation within the website, translation to execution of a transaction;
- **User Satisfaction:** Measures the entire customer experience cycle from purchase, payment, delivery and post sales service;
- **Net Benefits:** Measures the net positive or negative impact of e-commerce on our customers, suppliers, organizations, economy at a large scale and even to our society.

Wang (Wang, 2008) has re-specified the updated D&M IS success model and pointed out some improvement directions in the model. He suggested mainly four difficulties with the updated D&M IS success model. Firstly, the measure of Net Benefit is too broad to be defined appropriately. Researchers/Practitioners need to carefully identify the stakeholders to define the net benefit for them. Secondly, the measure of Intention to use can be reconciled with (Seddon & Kiew, 1996) perceived usefulness construct to provide theoretical richness for the model. Thirdly, the measures of usage and intention to use can be reconciled more appropriately w.r.t the marketing literature of customer satisfaction and loyalty. Finally, DeLone and McLean (DeLone & McLean, 2003) have kept their model open for validation and updating through empirical methods which keeps the model prone to uncertainty in using a concrete approach for measuring IS success for e-commerce. However, with highlighted weaknesses; Wang (Wang, 2008) also identifies D&M IS success model as a strong basis for identification of critical success factors/measures for IS success.

IS researchers also developed, tested and applied IS success models for e-commerce systems (D'Ambra & Rice, 2001; DeLone & Mclean, 2004; Liu & Arnett, 2000; Molla & Licker, 2001; Palmer, 2002; Teo & Choo, 2001). E-commerce primarily revolves around communication and transactions between suppliers and customers. D&M IS success model that is an IS success model based on communication theory syncs well with the structural and functional aspects of e-commerce (DeLone et al., 2016) and thus is best for identifying factors that attribute to e-commerce success. The theoretical underpinning of e-commerce and D&M IS success model promotes us to use D&M IS success model to identify those critical factors which impact the SCM-M interface of e-commerce and attribute to e-commerce success.

CRITICAL SCM-M INTERFACE FACTORS OF E-COMMERCE USING D&M MODEL

The updated D&M IS success model was used to explore critical factors of e-commerce success (DeLone & Mclean, 2004) and customer intentions for online purchase (Chen & Cheng, 2009). Petter (Petter, DeLone, & McLean, 2013) identified around 43 critical variables of e-commerce success using the D&M IS success model that were later classified into different functional categories. Repurchase intentions of customers in a group –buying setting were analysed and antecedents or critical factors corresponding to better re-purchase were identified using the D&M IS success model (Hsu, Chang, Chu, & Lee, 2014). The D&M IS success Model was also used to identify the Big Data Analytics perspectives in e-commerce (Akter & Wamba, 2016). Chen et al. (Chen, Su, & Widjaja, 2016) explored the constructs or critical factors that lead to impulsive buying behaviour from customers in an online purchase environment with Facebook acting as an advertising instigator. D&M IS success model was amalgamated with Self-Determination Theory (Samar & Mazuri, 2019) to for success in internet banking. Research

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

identifies D&M IS success model to be one of the main models to estimate and measure user intention for continues usage of technology (Antonopoulou & Kotsilieris, 2019). E-governance success constructs were also identified using the D&M IS success model (Scott, DeLone, & Golden, 2016). Based on research work performed by synthesizing the D&M IS success model and the E-commerce/Online business venues, we identify a list of metrics that can impact e-commerce success.

We do not claim this list of metrics for different dimensions of their model to be exhaustive, but they are certainly illustrative. Based on the metrics identified for factors of D&M model given that can be visualized in Figure 1, we will classify them into the categories of SCM, Marketing and SCM-M interface with a rationale of classification. Let us take these metrics for each dimension one by one (Tables 1 to 3).

Table 1. System quality metrics classification

Metrics	Reference	Classification	Rationale
Response Time	(Molla & Licker, 2001)	Marketing	Drives customer experience
Scalability	(Palmer, 2002)	SCM	Depends on SCM capabilities
Ease of navigation	(Molla & Licker, 2001), (Palmer, 2002)	Marketing	Drives customer experience
Security	(Molla & Licker, 2001)	SCM-M	Drives brand image as well as collaboration with Suppliers

Table 2. Information quality metrics classification

Metrics	Reference	Classification	Rationale
Customer Preference Information	(Molla & Licker, 2001; Peppers & Rogers, 1998)	Marketing	Drives customer experience
Completeness	(Palmer, 2002)	SCM-M	Possible with synergies of SCM-M
Competitive Intelligence	(Teo & Choo, 2001)	SCM-M	Possible with synergies of SCM-M
Variety of information	(Palmer, 2002)	Marketing	Drives customer experience

Table 3. System use metrics classification

Metrics	Reference	Classification	Rationale
Processing Customer Orders	(Young & Benamati, 2000)	SCM	Depends on SCM capabilities
Processing Purchase Orders	(Young & Benamati, 2000)	SCM	Depends on SCM capabilities
Customer Service request	(Young & Benamati, 2000)	SCM	Depends on SCM capabilities

Net benefits are classified into four categories of Individual benefits, Group Benefits, Organizational benefits and Industry benefits. Useful metrics from each category is analysed in Tables 4 through 7.

Now, with these identified critical factors under the dimensions of D&M IS success model for classes of SCM, Marketing and SCM-M interface, we use scenario-based planning to strategize on leveraging the SCM-M interface for the success of e-commerce.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Individual benefits metrics classification

Metrics	Reference	Classification	Rationale
Customer Support	(Raghunathan & Madey, 1999)	SCM	Depends on SCM capabilities
Enhanced customer knowledge	(Loftus, 1997)	Marketing	Drives customer experience
Enhanced customer experience	(D'Ambra & Rice, 2001)	Marketing	Drives customer experience
Reduced costs	(D'Ambra & Rice, 2001)	SCM-M	Possible with synergies of SCM-M
Real-time marketing	(D'Ambra & Rice, 2001)	Marketing	Drives customer experience

Table 5. Group benefits metrics classification

Metrics	Reference	Classification	Rationale
Selling Team Coordination	(Loftus, 1997)	SCM-M	Depends on synergies of SCM-M

Table 6. Organizational benefits metrics classification

Metrics	Reference	Classification	Rationale
Increased Sales, Market-Share and Profits	(Griffith & Krampf, 1998; Teo & Too, 2000)	Marketing	One primary intent of Marketing domain
Competitive advantage	(Takacs & Freiden, 1998)	SCM-M	Possible with synergies of SCM-M
Productivity efficiency	(Barua, Konana, Whinston, & Yin, 2001)	SCM	Depends on SCM capabilities
Operational excellence	(Morash & Clinton, 1998)	SCM	Depends on SCM capabilities
Reduced Cycle Time	(Hoogeweegen & Wagenaar, 1996)	SCM	Depends on SCM capabilities
Brand Awareness	(Teo & Too, 2000)	Marketing	Success measurement metric for marketing
Customer Responsiveness	(Hoogeweegen & Wagenaar, 1996)	Marketing	Success measurement metric for marketing
Market Responsiveness	(Teo & Too, 2000)	Marketing	Success measurement metric for marketing

Table 7. Industry benefits metrics classification

Metrics	Reference	Classification	Rationale
Supply Chain Efficiency	(Baron, Shaw, & Bailey, 2000)	SCM	Depends on SCM capabilities
Supply Chain integration and synchronization	(Morash & Clinton, 1998)	SCM	Depends on SCM capabilities

SCENARIO PLANNING AND FUZZY COGNITIVE MAPS

Scenarios help us to outline some situation of the future. *Webster's New Collegiate Dictionary* defines a scenario as "An imagined sequence of events, especially a synopsis of possible events, actions or possibilities". Van der Heijden (Van der Heijden, 1996) presented the following five conditions for a scenario:

- At least two scenarios are needed to reflect uncertainty;
- Each scenario must be plausible;
- Consistent;
- Relevant;
- Produce some new and original perspective on issue of concern.

Porter (Porter, 1991) identified two main categories of scenarios, namely:

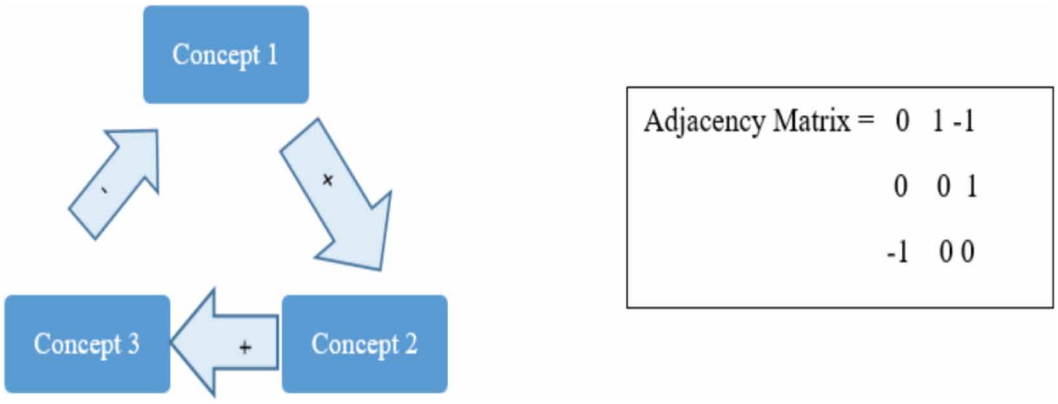
- Normative (planning and attaining desired goals);
- Descriptive (present a range of future alternatives).

A scenario-based planning brings a coherent, plausible, systematic and comprehensive plot in dispersed and complicated elements (Coates, 2000). The main purposes of scenario planning (Coates, 2000; Porter, 1991) are identified as follows:

- Scenario stimulates thinking by story-telling about a future event, condition or generate choices and alternatives;
- Establishes consequences/impacts of a particular choice;
- Forms a basis for further research.

Cognitive Maps capture diverse mental models for scenario development to identify key concepts or critical factors of the problem at hand and explore alternatives for future (A. Jetter & Schweinfort, 2011). Cognitive maps are directed graphs consisting of nodes (concepts) with positive or negative relationship (weights on edges/arrows) (Kosko, 1986). These relationships express dependencies between concepts

Figure 4. Causal cognitive map (adapted from (Shukla, Mohanty, & Kumar, 2018))



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and hence establishing a causality relationship. A simple illustration for causal map with its adjacency matrix is shown in Figure 4.

Figure 4 presents the adjacency matrix describing the crisp (either positive, negative or neutral) relationship between each concept of causal cognitive map. Kosko (Kosko, 1986) proposed Fuzzy Cognitive Maps (FCM) which are extensions to the cognitive maps (Axelrod, 1976); that help in analysing dynamically changing causal map representing real time situations with fuzzy weights assigned to relationships. Fuzzy Cognitive Maps (FCM) is a technique based on the concepts of an Artificial Neural Networks and Fuzzy Logic.

As mentioned above, most simulation methods revolve around simple rule-based scenarios (Vascak & Madarasz, 2010) or narrative storylines that are linked to dynamic models in an iterative process (Kok, 2009). But such methods cannot model complex situations where components are connected through chains and loops or components are a mixture of quantitative and qualitative factors. Fuzzy Cognitive Maps (FCM) can be used to model such complex situations and develop scenarios which can encapsulate human understanding and notations due to their graphical representation. A key tenet of FCMs is their additional capability of modelling complex relationship between concepts with appropriate weights on the edges (Kosko, 1997) which are fuzzily defined. A decision maker's perspective is understood in a realistic way with the usage of Fuzzy Logic (Jetter, 2003). In addition, a structural similarity of FCM and neural networks is the application in modelling complex systems (Kandasamy & Smarandache, 2003). FCM also helps decision makers to rationally involve all key factors of a problem situation and analyse different decision alternatives (Jetter, 2006). A decision maker can analyze inference patterns in a more realistic way (Kosko & Dickerson, 1994) using FCM. FCM are used in a variety of domains ranging from Forecasting (Li, Cheng, & Lin, 2008; Salmeron, 2012), Strategic planning (Kardaras & Karakostas, 1999; Lee, Lee, Kwon, Han, & Yu, 1998; Shukla et al., 2018) Decision Making (Iakovidis & Papageorgiou, 2011; Yu & Tzeng, 2006), Explanation (of actions already made) (Chen & Zhang, 2004), etc.

The problem addressed in this paper of strategizing SCM-M interface for e-commerce success can be systematically handled using FCM. A graphical map is formed by the collection of SCM-M interface critical factors and causality between these concepts/factors is defined vaguely or fuzzily. Dynamic scenarios proposed by the stakeholders based on FCM help in strategic planning of SCM-M interface for e-commerce success.

Now we discuss some basic concepts centred on FCM based on the foundational work of Kosko (Kosko, 1986) on FCMs. Let us assume that there are n concepts in a FCM namely: $C_1, C_2, C_3, \ldots, C_n$. The amount of causality imparted by any concept C_i to C_j is $e_{ij}=e(C_i, C_j)$, which represents the fuzzy weights allocated for each relationship. E is the adjacency matrix where $E = e_{ij1 \le i,j \le n}$ which represents a matrix containing weights of causal relationships of FCM. E contains all one-edge paths on cognitive map. $E^2 = E*E$ which represents all two-edge paths of cognitive map. Similarly, other matrices like $E^3, E^4, E^5, \ldots\ldots, E^{n-1}$ list indirect effects of three, four, five, ……, n-1 edge paths respectively.

FCMs are acyclic so no more than n-1 edges can exist in a path.

The total effect matrix also known as reachability matrix is defined as:

$$T = \sum_{i=1}^{n-1} E^i$$

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

T is nothing but the powered sum of matrices E^i. Acyclic nature of E can be determined to be positive if the main diagonal elements of T are all zero. To determine centrality of a concept in FCM, we define the following terms:

$$IN\left(C_i\right)=\sum_{k=1}^{n} e_{ik}$$

and:

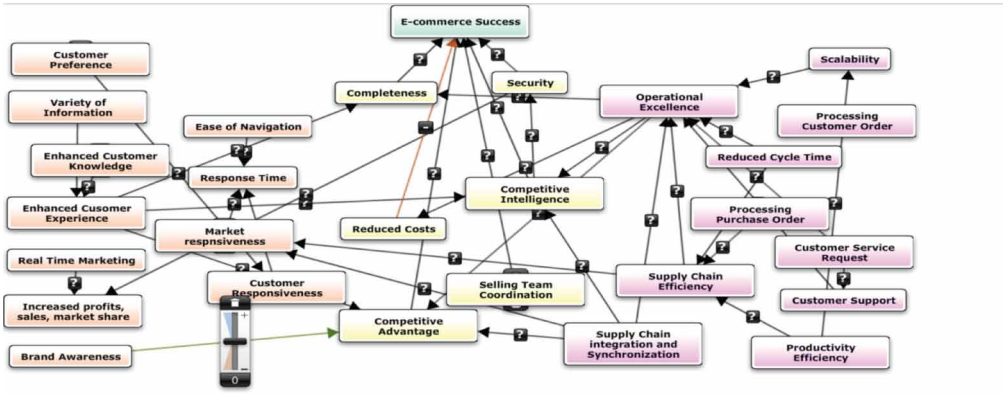
$$OUT\left(C_i\right)=\sum_{k=1}^{n} e_{ki}$$

where $IN(C_i)$ is the number of concepts casually impinging on concept C_i and $OUT(C_i)$ is the number of concepts C_i casually impinged upon. The conceptual centrality of a node C_i representing the importance of this node in causal map is thus defined by:

$$CEN(C_i) = IN(C_i) + OUT(C_i)$$

A concept might have more causal centrality if it is heavily connected to its connections although it might be connected to a lesser number of nodes. After explaining the basic concepts of FCM, we enumerate it using an illustration of the problem addressed in this paper (Figure 5).

Figure 5. Fuzzy causal cognitive map



Each connecting arrow with a question mark represents the input required from stakeholder, which is a confidence rating or fuzzy weights of one concept driving another. These fuzzy weights are nothing but the representation of understanding of stakeholders about the influence of one factor on another in a qualitative fashion (Nyaki, Gray, Lepczyk, Skibins, & Rentsch, 2014). These qualitative values that represent the understanding of the stakeholders which are then transformed into a quantitative value for FCM modelling which is elaborately shown later in the paper. The stakeholder or decision maker for a

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

specific problem situation at hand should provide these unattended weights. The arrow between Brand Awareness driving Competitive Advantage shows how we can allocate a fuzzy weight between -1 to 1.

The relationship of each concept can be expressed as a negative (high, medium, low), neutral, positive (high, medium, low) edge relationship. Gray et al., (Gray, Gray, Cox, & Henly-Shepard, 2013) developed openly available web-based mental modeler software to convert these qualitative relationships in mind of a decision maker to convert them into fuzzy approximates between -1 and 1. Once the Decision Maker fixes his mind on the relationship between these critical factors of SCM, Marketing and SCM-M interface identified through D&M IS success model, the relationship is converted into the fuzzy weights and thus into a response matrix. Variations in one concept help to determine the impact on the other concepts, E-commerce success and system as a whole.

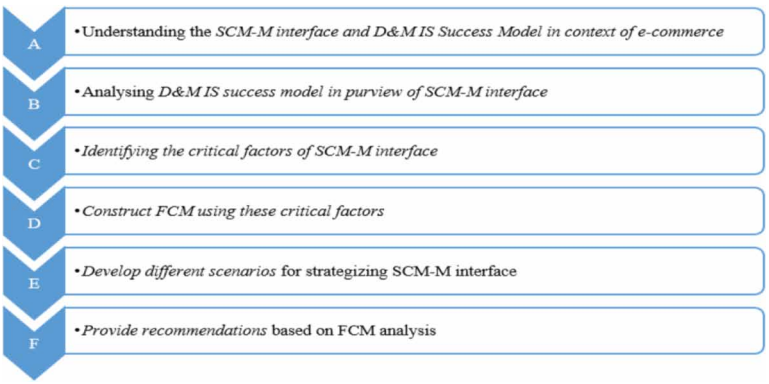
RESEARCH METHODOLOGY

We propose an integrated mechanism to identify the critical SCM-M interface, Marketing and SCM factors in e-commerce using D&M IS success model (DeLone & McLean, 2003) and explore and evaluate dynamic scenarios between these factors. These scenarios are based on FCM, which help to strategize e-commerce success using critical factors of SCM-M interface, SCM and Marketing. The following main modules constitute the research methodology:

1. Understanding the SCM-M interface and D&M IS Success Model in context of e-commerce;
2. Analysing the different dimensions of D&M IS success model in purview of SCM-M interface;
3. Identifying the critical factors of SCM-M interface, SCM and Marketing using D&M IS success model for strategizing e-commerce success;
4. Construct FCM using these critical factors;
5. Develop different scenarios for strategizing SCM-M interface for e-commerce success to aid situational decision making;
6. Provide recommendations based on FCM analysis.

Based on the work presented in previous sections of this research paper, we present a systematic illustration of each section of this flow diagram.

Figure 6. Flow diagram of proposed the research methodology



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

1. Understanding the SCM-M Interface and D&M IS Success Model in Context of E-Commerce.

In section 2 and 3, we presented an in-depth review of previous research works to better understand the SCM interface and D&M IS success model in the context of e-commerce.

2. Analysing D&M IS Success Model in Purview of the SCM-M Interface.

In section 4, we explored different dimensions of D&M IS success model and related the important metrics of each dimension to the SCM-M interface, SCM and Marketing.

3. Identifying the Critical Factors of the SCM-M Interface.

We derived a set of critical factors important for SCM-M interface, SCM and Marketing for e-commerce success using the work by (DeLone & Mclean, 2004). The set of identified critical factors are presented in Table 8 with their classification in SCM-M interface, SCM or marketing with appropriate abbreviations to be used later in our work.

4. Construct FCM Using These Critical Factors.

The critical factors identified using D&M IS success model help in constructing FCM. These critical factors form integral components of FCM known as concepts and the decision/problem situation at hand helps to define the relationship between them. FCM also enables decision makers to allocate their understanding on strength and direction of relationship in form of fuzzy weights. After defining these relationships and weights, FCM is subjected to scenario generation and analysis.

5. Develop Different Scenarios for Strategizing SCM-M Interface.

We develop different scenarios based on FCM in the section 7 and analyze them.

6. Provide Recommendations Based on FCM Analysis.

We provide recommendations based on scenario analysis in section 7. The results of these scenarios help a decision maker to strategize e-commerce success using the critical factors of SCM-M interface identified using the D&M IS success model.

STRATEGIC PLANNING TO LEVERAGE SCM-M INTERFACE FOR E-COMMERCE SUCCESS

The FCM of critical factors of the SCM-M interface, SCM and Marketing identified through the D&M IS success model is presented in Figure IV. However, the fuzzy weights need to be assigned for representing the relationship strength between concepts. The decision maker can qualitatively classify these weights into seven values: positive relationship (high, medium, low), neutral or negative relationship (high, medium, low). These weights represent a fuzzy membership degree of (0.33, 0.66, and 1) for a

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

positive relationship while a negative relationship is represented as a negative value (-0.33,-0.66,-1) of these fuzzy membership degrees. The neutral relationship is represented with membership degree zero. These fuzzy weights are nothing but the representation of understanding of stakeholders about the influence of one factor on another in a qualitative fashion (Nyaki et al., 2014). Hence, a Decision Maker can assign the following qualitative values to each relationship.

HP, MP, LP, N, LN, MN, and HN: Representing Highly Positive, Medium Positive, Low Positive, Neutral, Low Negative, Medium Negative or Highly Negative. It is very important to have a rationale for assigning these fuzzy weight values to relationships between concepts. Two types of relationships primarily exist between the concepts or critical factors identified for SCM-M interface, SCM and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Marketing. First type of relationship is the one that exist directly between a concept and e-commerce success, which is the strategic goal of FCM. The second type of relationships are those that exist between a concept and other concept.

We present a tabular representation (Table 9) of those concepts/critical factors, which directly affect the e-commerce success, and the fuzzy weights assigned to their relationship with the strategic goal of e-commerce success. In our case, we have identified that only SCM-M interface critical factors will directly impact the e-commerce success to emphasise on the synergies between SCM and Marketing. However, this choice is dependent completely on the stakeholders and problem situation at hand. The concept names are presented in their abbreviated form as mentioned in Table 8.

Table 9. Relationship of concepts with e-commerce success

Critical Factors/Concept of FCM	Fuzzy Weight/Value
SE	HP
CO	LP
CI	MP
RC	LP
STC	HP
CA	HP

Now, we present a tabulated visual of interrelationships among concepts or critical factors (Table 10). These relationships are in the form of antecedent-consequent where the prior concept drives the later one. We use abbreviated form of concepts to represent these relationships.

The rationale behind qualitative values assigned by the decision maker in case of both types of relationships expressed in Tables 9 and 10 needs to be understood. We have considered all the critical factors or concepts considered in FCM to possess a positive impact on e-commerce success, so all the fuzzy weights assigned are primarily positive. Let us explain the rationale of fuzzy weights for a couple of entries in both the tables. In Table 9, we consider Security (SE) and Competitive Advantage (CA) to bear a highly positive (HP) relationship with e-commerce success. In case of interrelationships between critical factors/concepts given in Table 10, Customer Experience (CE) drives Competitive Intelligence (CI) in medium positive (MP) manner whereas drives Competitive Advantage (CA) in a highly positive (HP) manner. Based on the fuzzy relationship weights given above in Tables 9 and 10, a scenario is generated as shown in Figures 7-10.

Figure 10 represents FCM in the default state where we have the relationship of concepts and strategic goal with their weight values provided by the Decision Maker. In order to study the impact of variations of a particular concept on the strategic goal, we vary the concept values. There are primarily four main functions available for these variations in concept values based past research work and offered by Mental Modeller (Boutalis, Kottas, & Christodoulou, 2009; Gray et al., 2013; Kosko & Dickerson, 1994). These functions are:

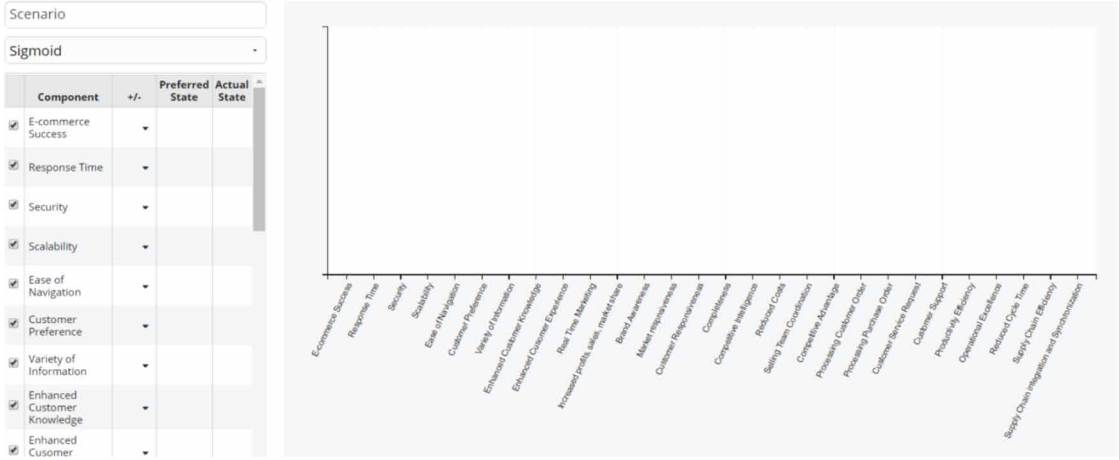
Figure 10. Default state to perform variations in concepts



- **Bivalent:** The usage of this function allows measurement of variation in two crisp value of either 0 (concept activated) or 1 (concept not activated);
- **Trivalent:** The usage of this function allows measurement of variation in three crisp values: either 0 (concept stable), -1(concept decreased) or 1(concept increased);
- **Sigmoid:** The usage of this function squashes the variation between two saturation levels 0 and 1 to create continuous state FCM;
- **Hyperbolic Tangent:** The usage of this function squashes the variation between two saturation levels -1 and 1 to create continuous state FCM.

We have used Hyperbolic Tangent Function for defining these changes over the already existing fuzzy membership of concepts as shown in Figure 9. Hyperbolic Tangent Function ensures that concepts can take variation values between -1 and 1 to express the strength and nature of their relationship appropriately (Bueno & Salmeron, 2009).

These variations will help us better understand the impact of changing concept on the strategic goal of e-commerce success. The following variations are performed:

- We start the scenario-based analysis by decreasing the Security (SE) by 0.1. We observe a tragic fall of 0.15 in e-commerce success and the profitability concept (IPSM) being hampered by 0.15;
- In the next step, we further worsen the situation by decreasing the Supply Chain efficiency (SCE) by 0.3. We find that the impact of decrease in both the Security (SE) and the Supply Chain efficiency (SCE) brings a highly negative impact on whole system. Strategic goal of e-commerce success along with factors like the Response Time (RT), Market Responsiveness (MR), Reduced Cost (RC), Operational Excellence (OE) etc. receive a big dip on their performance;
- Next a positive movement of the Supply Chain efficiency (SCE) from -0.01 to 0.1 recovers major losses to e-commerce success; brings back all the critical factors to a positive performance except the profitability concept (IPSM);

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Further, a positive movement of the Sales Team Co-ordination to 0.1 gives the entire e-commerce system an increased positive momentum. However, this change is unable to affect the ISMP (Increased Sales, Market Share and Profits);
- Lastly, we make a positive movement of Security (SE) from -0.01 to 0.1 which highly affects the e-commerce success as wells as brings the profitability concept (IPSM) to a positive state of contribution for e-commerce success.

Figures 11-15 give a visual representation of these variations.

Figure 11. Visual representation of variation in scenarios (variation in security) SE decreased by 0.1

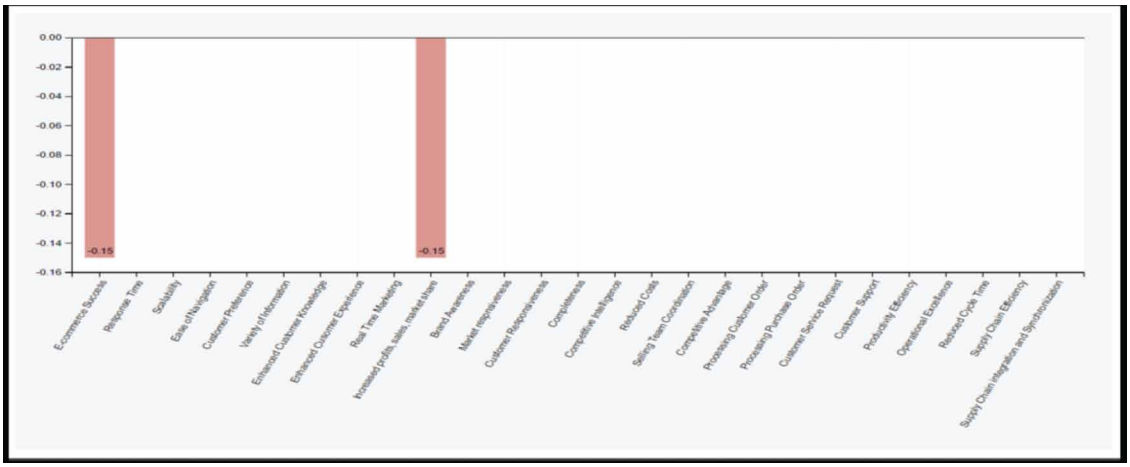


Figure 12. Visual representation of variation in scenarios (decrement in supply chain efficiency) SCE decreased by 0.3

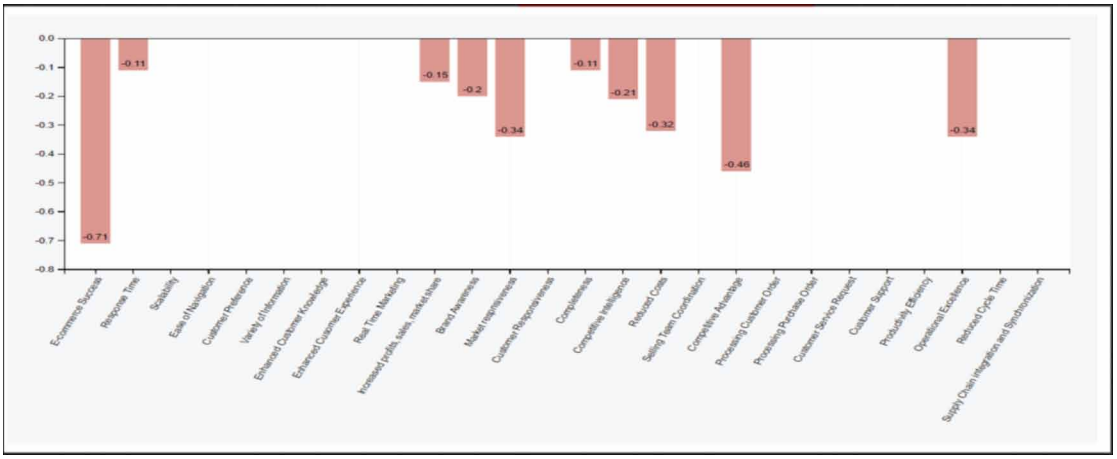

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 13. Visual representation of variation in scenarios (increment in supply chain efficiency) SCE increased by 0.1

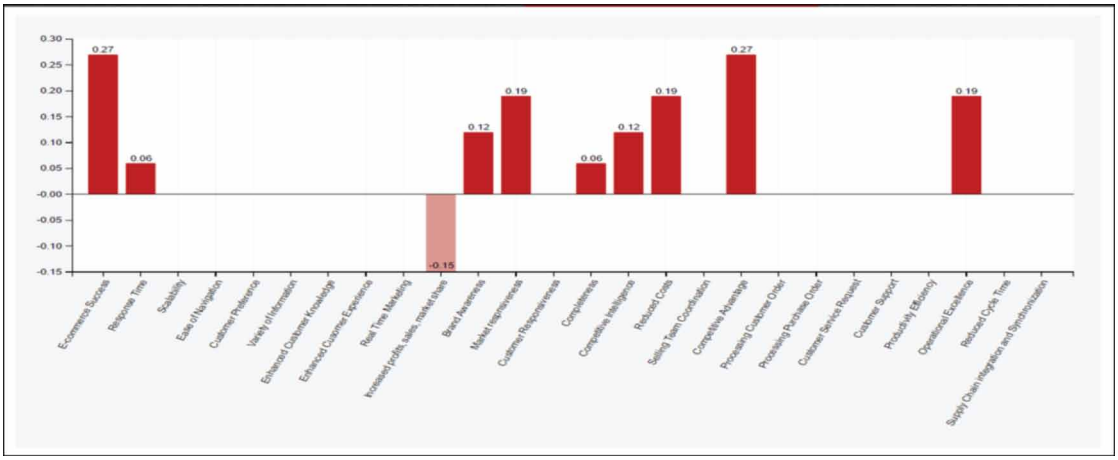

Figure 14. Visual representation of variation in scenarios (increment in sales team coordination) STC increased by 0.1

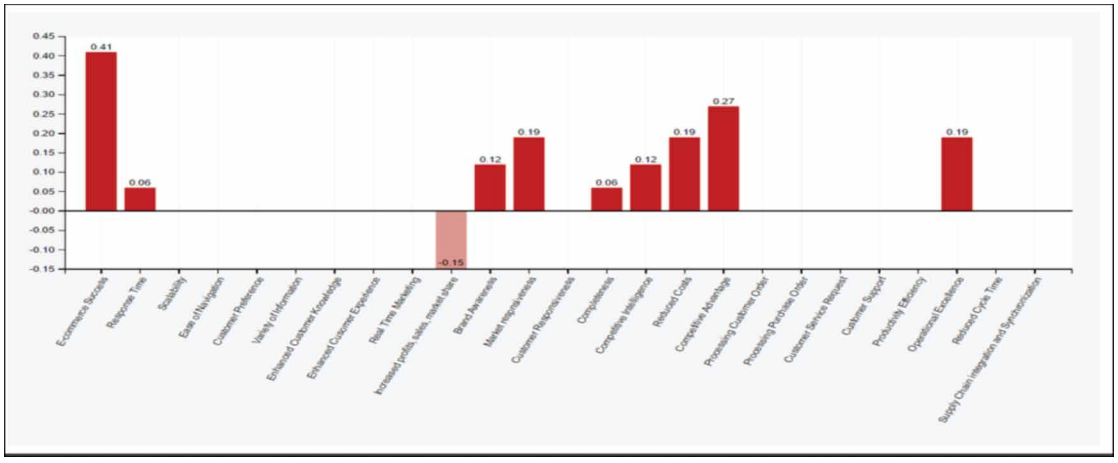

Figure 15. Visual representation of variation in scenarios (increment in security) SE increased by 0.1

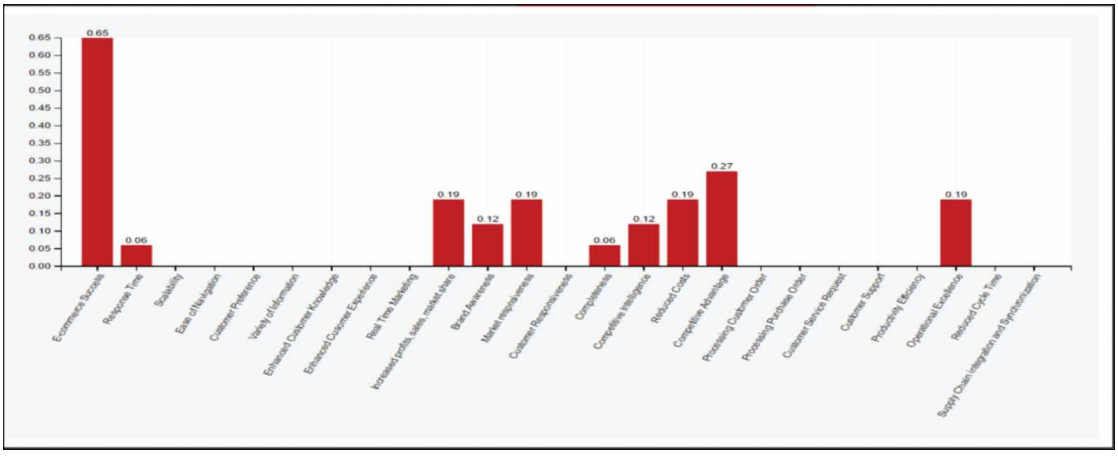

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The results of this scenario analysis based on FCM is presented in the next section along with the highlights from the results.

RESULTS OF SCENARIO-BASED ANALYSIS

The results of scenario-based analysis performed for strategizing SCM-M interface for e-commerce success are presented in Table 11.

Table 11. Results of scenario-based analysis

Steps of Variations	Variations of Concepts	Variation Strength and Direction		Undesirable Changes	Desirable Changes
		Variation	New Level		
1	Security	.1(Decrease)	-.01	Profitability decreased, E-commerce Success decreased	
2	Supply Chain Efficiency	.3(Decrease)	- .01	Response Time, Market Responsiveness, Reduced Costs, Operational Excellence, Profitability, E-commerce Success are all decreased	
3	Supply Chain Efficiency	.2(Increase)	+.01	Profitability still negative	Response Time, Market Responsiveness, Reduced Costs, Operational Excellence, E-commerce Success are all at same positive level
4	Sales Team Co-ordination	.1(Increase)	+0.1	No effect	No effect
5	Security	.2(increase)	+0.1		Profitability increases

The above results of the scenario-based analysis using FCM provide the following fresh insights into the problem of strategizing the SCM-M interface for e-commerce success (as well as other related business problems):

- An important observation from these variations in critical factors for the given scenario is the identification of security (customer value related) and supply chain efficiency as a key factor to influence the e-commerce success and profitability. (Scenario Specific) The business implication that draws from this scenario-based fact is that security being a concern for both demand and supply side should always be maintained at an optimum level;
- Fuzzy weights assigned to the relationships for a FCM play a key role in defining the impact of variations of a particular concept on other related concepts as well as the strategic goal;
- The fundamental concepts are linked to the strategic goal of sustainability as well as inter-connected with each other. The variation in a fundamental concept in purview of the improved attainment of the strategic goal might negatively or positively affect other related concepts;

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- A decision maker with different rationale for relationships between the concepts might attain a different set of results as per the case description.

CONCLUSION AND IMPLICATIONS

This paper presents a unique and practical approach that helps to identify the critical factors affecting e-commerce success using the D&M IS success model, and the scenario-based analysis of FCM helps to measure the impact of these factors on the strategic goal of e-commerce success. This information can be useful to decision makers or stakeholders in prioritizing alternatives in decision making under business situations at hand.

This research also has some significant managerial implications:

- This paper discusses a complex problem of strategizing the SCM-M interface of e-commerce success. The proposed framework can help practitioners to view a complete picture of this problem and invoke them for better decision making;
- FCM provides different decision makers or stakeholders with an opportunity to express their understanding of the different concepts driving SCM-M interface and each other in a qualitative fashion, which is largely acceptable and understandable;
- The visual appeal of the scenario-based analysis provides the ability for an easy understanding and handling of the model for the decision makers and stakeholders with all backgrounds. The decision makers who lack the knowledge of the complex modeling methods or the other artificial intelligence and soft computing techniques can easily adopt this approach;
- We can also construct multiple FCMs for the viewpoint of multiple stakeholders and draw conclusions for community-based decisions;
- Lastly and most importantly, using the D&M model of IS success for identifying the fundamental concepts of e-commerce success by the stakeholders ensures the acceptability of this approach in a particular decision situation. Further, the usage of FCM by stakeholders to express their understanding for relationships among concepts ensures the flexibility part of this approach.

LIMITATIONS AND SCOPE OF FURTHER RESEARCH

One of the important limitations of our work is classification of the critical factors identified primarily through work of (DeLone & Mclean, 2004) and other past research works. We have considered a self-defined rationale to classify the identified critical factors in the domains of SCM, Marketing and SCM-M interface. In addition, we do not expect this list of critical factors in our work to be exhaustive for all possible factors possible in these domains. However, we have tried to incorporate as many critical factors as possible and identifiable through appropriately connected research works.

The research methodology presented in this work is based on attaining the strategic goal of e-commerce success by harnessing the SCM-M interface. We have used FCM to model the critical factors affecting e-commerce success. The relationships identified and the values assigned to the relationships are based on the stakeholder choice. An important extension to this work can be the testing and validation of this methodology with some actual data and business situations. The test with actual data and business situ-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ation might help in improvisation of this methodology and lead to better understanding, analysis and results in an updated model.

ACKNOWLEDGMENT

We want to thank the team of http://www.mentalmodeler.org for making the mental modeler software freely available (The software has been used for executing the FCM in the paper). We also want to thank the comments from anonymous reviewers which made this work more refined and focussed in presenting the research idea.

Chapter 11
Strategies to Predict E-Commerce Inventory and Order Planning

Mohammad Anwar Rahman
Central Connecticut State University, New Britain, CN, USA

Laura Casanovas
Central Connecticut State University, New Britain, CN, USA

ABSTRACT

This study examines the characteristics of a prediction model for businesses in the online marketplace by considering the market trend, prior sales and decision maker's preference on potential demand estimate. With the rapid growth of the electronic market, the main challenge for online sellers is the ability to analyze customer expectation, market data, and sales information to make the accurate procurement decision. The proposed model integrates a mathematical structure for a target season sale comprising upcoming demand projection by seller's internal team, data from past sales and the overall trend of seller's e-brand to determine the online customer demand. The study proposed a newsvendor model as a tool for sellers to make the instantaneous decision of ordering merchandise from the supplier when the quick response to the customer order is a priority for electronic market. Results of the study provide insights into the procurement dynamics and implications of the e-commerce inventory plan.

INTRODUCTION

The advance of e-commerce made the online shopping popular among the users. E-commerce brought a trade revolution by providing an information platform for all levels of firms to participate in the online market with the scope of instant communication. The visibility of transaction, abundant information, low investment and low manpower, quick start-up and reduced inventory are the main attraction for the e-commerce growth. The accurate prediction of e-commerce merchandise plays an important role in business success. In particular, demand prediction in the e-commerce market has the task to efficiently

decipher the rhythm of the popularity, market trend and customer expectation. As evident, the businesses use networks for buying and selling goods and services, share information, transfer data and funds on the web system. E-commerce provides many benefits to both sellers and buyers and due to these advantages of the online business model over the traditional physical retailers, the expectations on e-commerce are increasing (Lee et al., 2007). On time delivery- and cost-intensive inventory set-up processes in the e-commerce industry provide the major motivation for customers to purchase their goods online in a more continuous way.

The challenge in e-commerce business is to find applicable inventory management policy to replenish items to meet consumer expectation. Technology is a key enabler to create real-time inventory demand pattern and replenishment policy by transforming traditional inventory practices to strategic point-of-sale e-commerce function. As technology advances, e-commerce business policy should be robust to replenish inventory at right time and at right quantity to keep the business growth effective. The service activities of all delivery requirements upheld on time, whereby priorities for customer orders can be achieved. Several ways e-commerce plays an important role as a business medium. E-commerce operations involve four major markets segments: business to business (B2B), business to consumer (B2C), consumer to consumer (C2C), and consumer to business (C2B). It has allowed firms to establish a market presence by providing a cheaper and more efficient distribution chain for their products or services. However, the central focus of this study is the business-to-customer e-commerce, as defined by Grandon and Pearson (2004): the process of buying and selling products or services using electronic data transmission via the Internet and the www. The study refers to the actual prediction process specific to the consumer demand and therefore falls in the area of operational decisions.

Many e-commerce businesses have successfully achieved tangible improvements in operational efficiency and financial revenue by integrating e-commerce into their value chain activities (Brynjolfsson & Kahin, 2000). However, not all firms have been uniformly successful (Barua & Mukhopadhyay, 2000). A vital practice to have in place in order to be successful in e-commerce is the ability to use prediction model to determine the stock level properly. If there is no standard process in place to predict for future business, the business will never be able to grow. There are several aspects of macro level emphasize on demand forecast ratio to be considered in order to maintain the proper inventory for e-commerce. A major aspect is knowing is knowing the sales and demand data of the product line in the past years. Understanding the customer demand pattern to able to predict what they will want and how much they will need is a breakthrough for success. In order to stock properly for e-commerce, the company should know the current inventory levels, sell-through rates, seasonal peaks, gross margin, product gaps, cash flow and product similarity (Roggio, 2015). Building a relationship and brainstorming between company's policy makers, designers, and the supplier (or manufacturer) representatives can have a significant impact on proper stocking with e-commerce. Popularity information effects online sales. For example, if a product is displayed on the hit list, product sales increase by an average of 1.3 units per day (Yoo et al., 2016). Their research identified the effects of popularity information on product sales through an analysis of the customer category and price. These representatives can project the impact of new design, the new style of customers, current business trend as well as the negotiated terms with delivery times, issues and allocations as necessary. Logistics evaluation and user-centric information systems provide a comprehensive platform to examine the latest strategies and methods for creating technological systems with end users as the focal point of the e-commerce design process (Saeed et al., 2017). E-commerce platform provides small businesses and individuals to launch online storefronts quickly with minimal start-up costs, although competition is intense. E-merchants must build customer trust if they are to sur-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

vive and grow in a marketplace where transactions are usually among strangers and sellers' reputations have a strong, positive impact on consumer trust and subsequent purchase intentions, price premiums, and sales volumes (Bente et al., 2012; Utz et al., 2012; Zhang, 2006). Successful practices of human-centered system design on e-commerce platform provides special attention to improve practices and designs, as well as the successful implementing Information and Communication Technologies (Saeed et al. 2014). Compared with traditional retail, online markets present lower entry barriers and higher profitability (McKinsey, 2013).

Over the past three years, global online sales have increased more than 20 times, while the US over and China's online sales have increased over 12 times and 12 times, respectively, amounting to global 2.6 trillion (US $595.1 billion, China $766.5 billion) in 2015 (Global B2C E-commerce Report 2016). In e-commerce, both large corporates such as Alibaba, Amazon, Apple and professional organizations, retail chains, banks, investing and rentals use the e-commerce market to their advantage. Small local businesses such as photographers, hair and nail salons, and fashion goods sellers also benefit from e-commerce platform to sell their products and services. It makes it easier for business to reach and allow interaction with their customers as well as facilitate online advertising and marketing. The leading online marketplaces of the Alibaba Group have annually 255 million active buyers, eight million active sellers, and 12.7 billion orders (Alibaba Group Holding Limited, 2014). In 2013, Amazon's sales reached US$74.4 billion, while Taobao.com, the biggest C2C website in China, exceeded US$179.2 billion. Obviously, in such an active market, producer and sellers have difficulties in keeping pace with new products, contemporary fashion and customer demand pattern.

E-commerce success includes performance issues, such as response time, international procurement lead time, or large demands in a small-time frame, order completeness and traceability of product delivery. Although a premium or express shipping service is available to major e-retailers, the delivery time may perceive a limitation compared to purchase in a store. E-commerce uses Internet information for order management, inventory management, and demand forecasting, and thereby the production scheduling and transportation. A challenge for sellers is to analyze customer data gathered during the online pre-sales, sales, and after-sales services process, i.e., master data mining (Jelassi and Leenen, 2003). The collaborative planning on the Internet, communication, and understanding of the consumer behavior are important to process information. Additionally, a supply chain network, internal communications within the e-commerce supply chain ensure the customer orders commitment and product delivery promise.

E-commerce business platform offers a quick response to customer needs to be based on distribution channel to forecast market demand and order management. The procurement of e-business is critical as the demand is uncertain, varies with time. The traditional retail chain inventory replenishment and planning is not suitable to manage e-commerce distribution channels. When sale starts, customer demand seen to be stochastic. The added challenge to this prediction that e-merchandise quantity must be decided prior to selling season since the design and manufacturing the times take time. Often, the demand of e-commerce such as casual dress, shoe, and fashionable products is highly seasonal, which makes more difficult to predict and require a unique process to identify procurement quantity and manage inventory. In order to satisfy the customer needs and expectations, an integrated sales data assessment is the key to improving the e-commerce chain of suppliers, systems, and processes to achieve the goal.

The paper is organized as follows: Section 2 literature review, Section 3 research methodology, Section 4 empirical study, and Section 5 conclusions. Section 2 reviews the benefit of e-commerce on commodity market and trend. Section 3 outline the research framework. Section 4 describes the data analysis and the details of the empirical analysis for building a prediction model, based on which some

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

managerial implications will be derived. Finally, Section 5 presents the conclusions and explain the future directions of this research.

E-Commerce on Commodity Market

The idea of commerce has expanded to electronic commerce to conduct the trade globally. The scheme allows individuals, consumers and corporates to exchange value for goods and services with little to no barriers. As a segment of a larger business system, e-commerce operates in all four major markets segments (B2B, B2C, C2C, and C2B. It has allowed firms to establish a market presence by providing a cheaper and more efficient distribution chain for their products or services. The power of e-commerce is the facility to conduct the transaction via social media, e-mail, online catalogs, and other services. Many companies capitalize on e-commerce through social media, digital couponing, and targeted advertising.

Most large e-commerce corporates are multi-level companies that sell all kind of products such as books, DVDs, electronic items online. Amazon runs 7 websites to support their business globally, and offer over 20 million items for sale. They use a multi-tier inventory model where the flow takes place from the Amazon distribution center (Tier-1) to the vendors, manufacturers (Tier-3) and physical flow takes place from Tier-3 to Tier-1. These corporates use search engine integrated with advertising strategies that companies use online to promote their products and services and generate steady traffics and incredible return on investment (ROI). Unlike traditional ads, it has proven to be more an effective audience acquisition strategy and gained popularity among business owners and retailers for the opportunity to connect with new customers with search engines. It is common that customers to follow a link from a search engine results pages and reach to an e-commerce website that they never knew before.

There are many examples of e-commerce success including firms offering products/services that are standardized or can be delivered electronically, such as the success of software companies, information providers, or bookshops (Poon & Joseph, 2000). E-commerce, however, with all its advantages has a fair amount of limitations. There is a difficulty to standardize and deliver products online because of their inherent intangibility, simultaneity, intimacy and perishability (Metters, King-Metter, & Pullman, 2004). Another limitation of e-commerce is the lack of personal touch and day-to-day collective buying. Many retailers value the human relationship, gives them personal connectivity with consumers, which in turn allows further collaboration and cooperation.

Online B2B allows companies to cut costs in three ways. First, it reduces procurement costs by making it easier to find the cheapest supplier, and it cuts the cost of processing the transactions. Second, it allows better supply-chain management. For example, more than 75 percent of all Cisco orders now occur online, up from 4 percent in 1996. This connection to the supply chain allowed Cisco to reduce order cycle time from six to eight weeks to one to three weeks and to increase customer satisfaction as well. Third, it makes possible tougher inventory control. It can provide less out-of-stock situations, the ability to make rapid inventory adjustments, and reduced ordering and processing costs can make a very efficient company. Mobile e-commerce, m-commerce is the term used to describe the growing trend of using networks that interface with wireless devices, such as laptops, handheld computers or mobile phones to initiate or complete online electronic commerce transactions (Niranjanamurthy et al., 2013).

Managing inventory is one of the most critical tasks for the e-commerce business success. Coordinating with wholesale suppliers and independent producers to make sure items are available to customers at the right time or as soon as possible. The impact of Amazon, Dell computer, eBay, and others, on traditional retailing, caused a lot of new retailers to implement websites to reach commodity globally.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

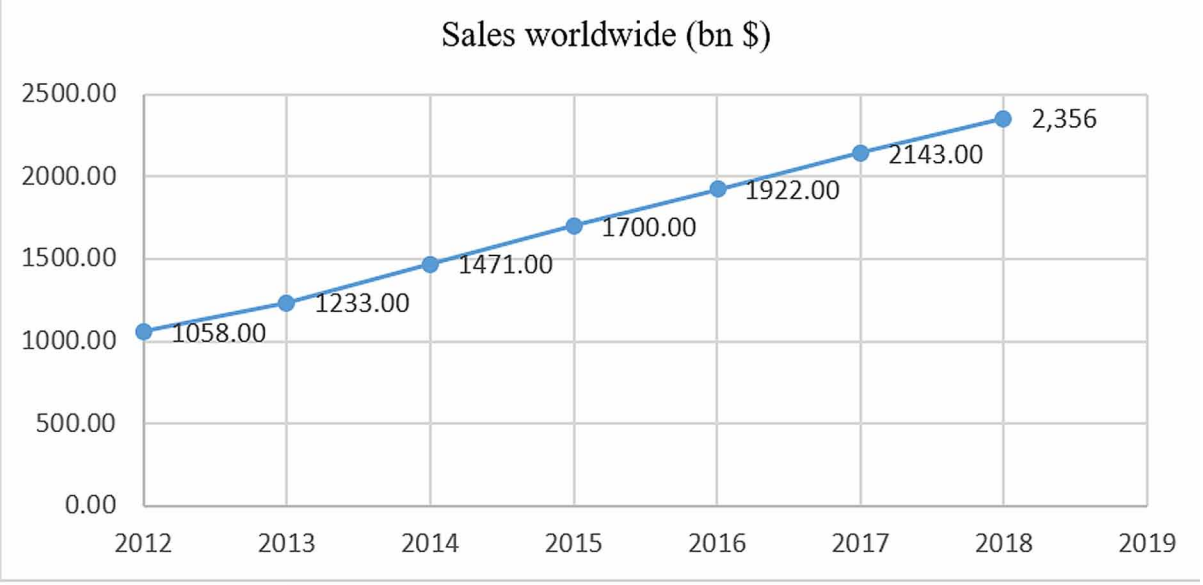
Although delivery of goods is a challenging task in web sales, there are premium examples of sustaining the challenge. In Japan, the 7dream program at 7-Eleven stores has the pick-up option in stores for web orders. This system now has been implemented throughout. FedEx, UPS, and other delivery packages in the same method in the US and offering parallel services to foreign customers. The major advantage of e-commerce on capturing customer taste, inventory procurement and order management are the following:

- Ability to navigate past behavior patterns of consumers, allows frequent analysis of consumer preferences and perceptions of purchases and sales
- Control on inventory replenishment policy and information on the value of the inventory·
- Visibility on quantities on hand, quantities order and quantities sold
- Collaborative and coordinated supply chain to reduce response time to demand changes
- Removal of unnecessary use of warehouse space used by unneeded part of inventory with advanced information of quantity, size and shape of merchandizing inventory.
- Information transparency to reduce excess inventory stock and costs.

E-Commerce Trend

E-commerce also has an impact on operations. The logistics behind large-scale e-commerce platforms are complex, the economies of scale are becoming progressively important, and it is now relatively easy for smaller firms to sell online because sophisticated e-commerce software is broadly available. The impact of the easy handling and on-going trends will change traditional distribution and marketing systems. Key impacts of e-commerce on marketing includes the marketing strategies of differentiation, which makes it easier to reach niche markets online. Although the product life cycles are shortened, the effectiveness

Figure 1. B2C e-commerce sales worldwide (2012 – 2018) (in billion $)



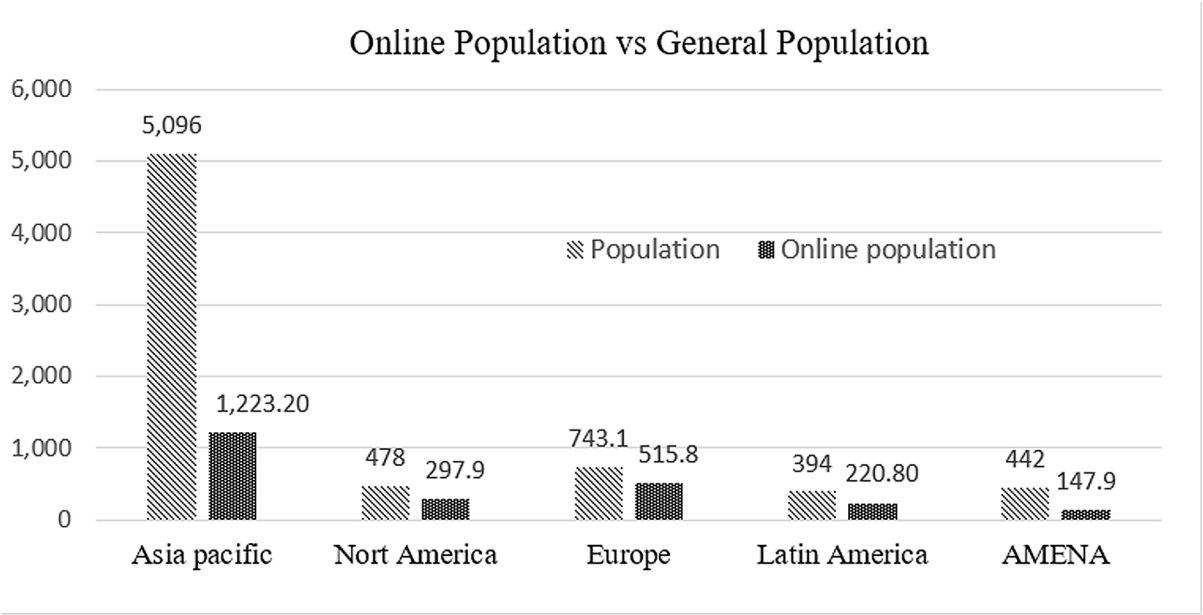
(Source: Global B2C E-commerce Report 2016)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of tracking system made it easy for new sales promotion, and the ability to sell a much wider range of products. Following is the graphics and statistics regarding e-commerce around the world. Figure 1 presents B2C e-commerce sales worldwide from 2012 to 2018 (in billion U.S. dollars).

This above graph (Figure 1) shows B2C e-commerce sales worldwide in 2012 and 2013 including a forecast until 2018. In 2016, global B2C e-commerce sales are expected to reach 1.92 trillion U.S. dollars. It can be attributed to the economic and technologic growth of the emerging economies and the largest growing markets. The four largest emerging and developing economies are the BRICS countries (Brazil, Russia, India, China, and South Africa). The next five largest markets are South Korea, Mexico, Indonesia, Turkey, and Saudi Arabia. The digital buyer e-commerce participation per region varies. Figure 2 demonstrates the number of digital buyers worldwide from 2014 to 2019 (in billions).

Figure 2. Number of digital buyers worldwide from 2014 to 2019 (in billions)



(Source: Global B2C E-commerce Report 2016)

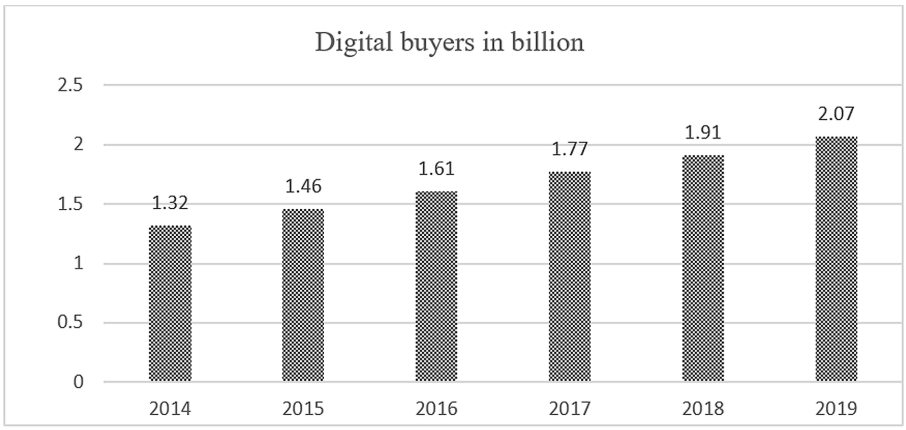
It is clear that, given the amount of population in Asia Pacific, the penetration of online population is not high. That means that the internet is basically available in the cities. The same proportion can be applied to Latin America and AMENA (Association of the Middle East and North Africa), where the level of development is not as high as the development countries. In contrast, North America and Europe have a much more penetration of online users which means that the availability of the internet is equally distributed throughout the country.

This timeline displays a forecast of the number of digital buyers worldwide up to 2019 (Figure 3), based on factual numbers from 2014 to 2015. In 2019, over 2 billion people worldwide are expected to buy goods and services online, up from 1.46 billion global digital buyers in 2015.

Purchasing goods and services online has become a common practice among many people around the world. Some choose to make online purchases for convenience, others because of the competitive price

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Digital buyers' prediction (2016- 2019)



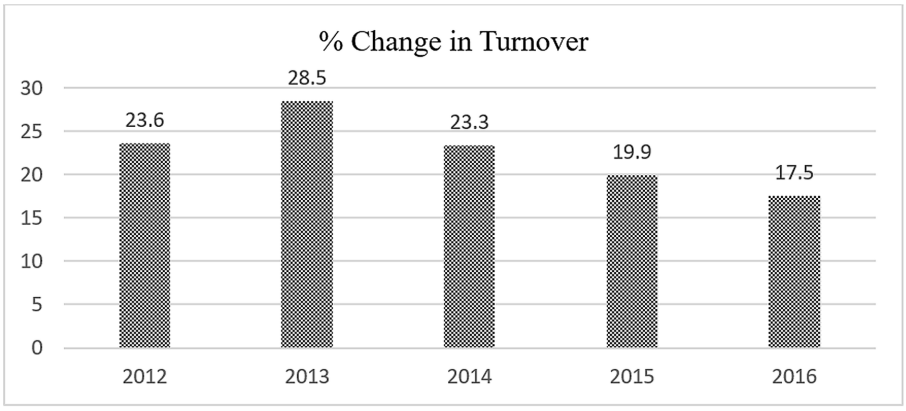
(Source: Global B2C E-commerce Report 2016)

offered by some e-commerce. Digital buyers can also be influenced by a range of digital resources when shopping, such as brand emails and product reviews. Reasons to purchase aside, the number of digital buyers is on the rise. Around 1.4 billion people made online purchases in 2015. This figure is forecast to constantly increase in the coming years, passing the two billion mark in 2019.

E-Commerce GDP

Global e-commerce sales have increased steadily, end the growth rate has been quite consistent as we can see in this graph. However, the result showed for 2016 indicate that the growth is not as high as before and it can be accredited to the settle of the global e-commerce market. See Figure 4.

Figure 4. Percentage (%) change in turnover



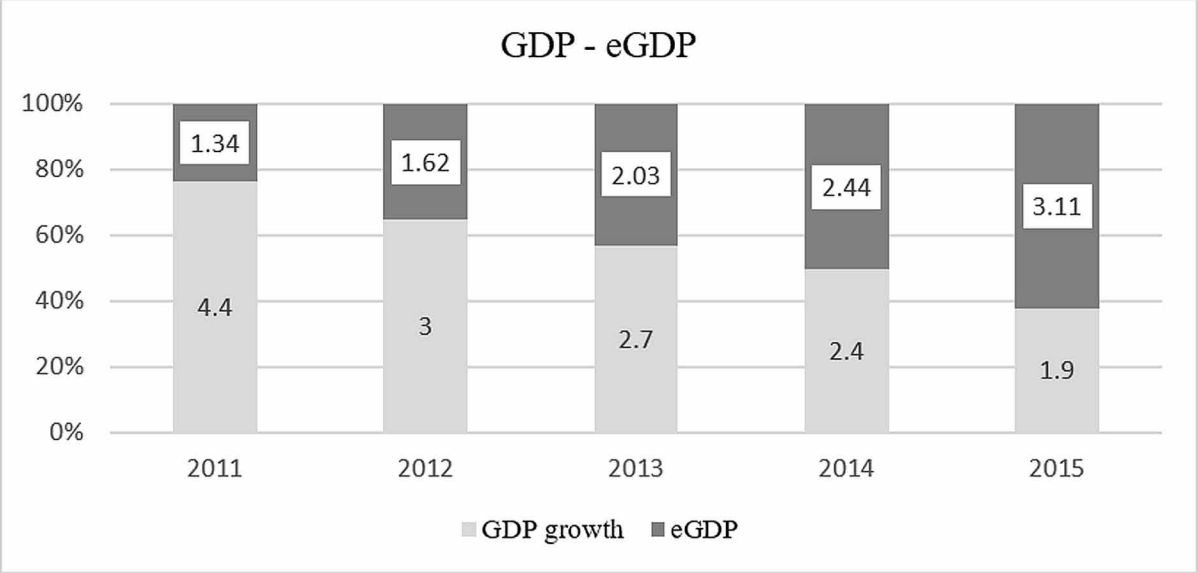
(Source: Global B2C E-commerce Report 2016)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Comparison of GDP with eGDP Per Year

GDP growth rate is decreasing. It was 1.9% in 2015 which was lower than the previous year 2.4%. In contrast, the share of e-commerce in the global GDP continued to increase. After reaching 1.34% in 2011, the eGDP raised gradually over the last few years to reach 3.11% in 2015. See Figure 5. The customer has been regarded as one of the most powerful forces in today's market place, equally important in e-commerce (Chen & Dubinsky, 2003; Shun & Yunjie, 2006). The customer expectation in e-commerce

Figure 5. Share of e-commerce in GDP of the total GDP growth



(Source: Global B2C E-commerce Report 2016)

is expected to increase in the formation of satisfaction.

This table and graphic shows the internet penetration (%) of the TOP 10 countries. The 10 countries together have a total penetration of 86% of the population (Figure 6).

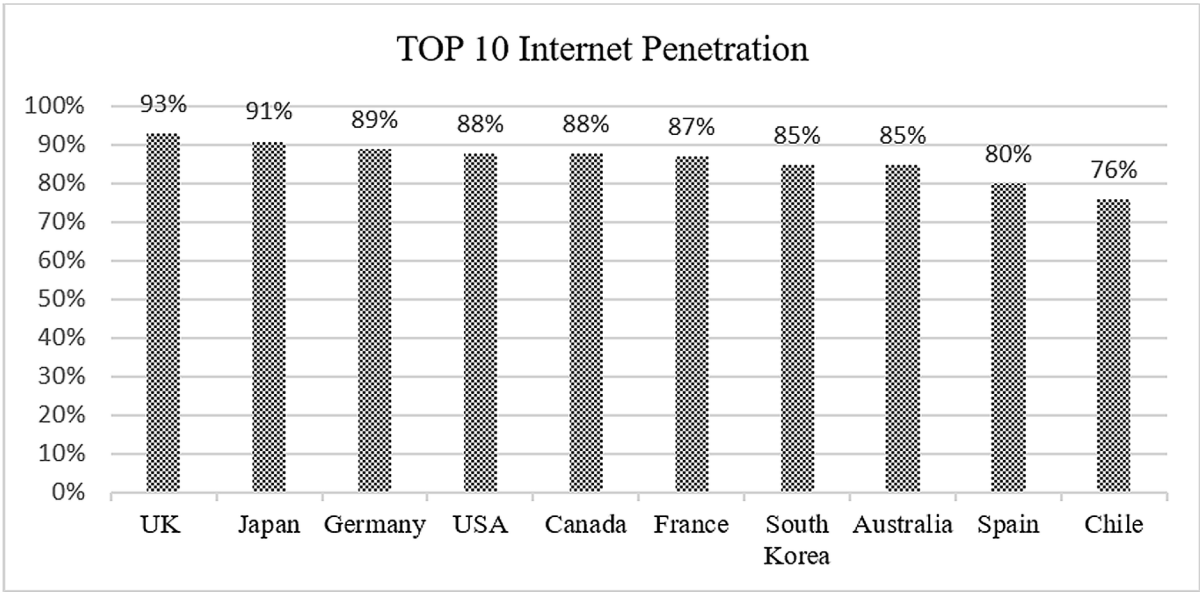
The above charts and diagram (Figure 5 and Figure 6) indicate customer participation in online marketing. Thus, customer perception on online service needs to be incorporated in establishing service strategy to predict customer's choice and future purchase intentions (Lee and Park, 2009).

INVENTORY PREDICTION SYSTEM

The success of e-commerce often describes with the ability to predict customers' intention to use e-commerce to buy a standard product. The matching of online demand with its supply is particularly challenging since the procurement decision must be made before observing demand. E-product demand

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Top 10 internet penetration (by country)



(Source: Global B2C E-commerce Report 2016)

is always stochastic. A decision tool is needed to understand the market in order to make the commitment to procure items before demand occurs. A newsvendor model may be applied in such settings, as the newsstand business model, to make the best judgment on how a firm decides to procure products for a given season. This scenario refers a considerable uncertainty in the e-commerce forecast despite the care and attention placed on the realization of the demand. The e-commerce demand forecasting decisions and order planning is actually the demonstration of managing strategy for e-merchant procurement and inventory. As traditional sales, the e-commerce involves in supply chain and warehouses to stock inventory. A firm needs to integrate the logistics process with the online ordering system to provide a uniform and seamless delivery system. The forecasting and replenishing inventory for the online products are sensitive due to the quick change of customer taste, style, and global competition.

E-procurement is fundamentally iterative in nature, which requires a deep understanding of customer needs, effective improvement and strategic modifications in designs, features, or schedule. The prediction model determines how much inventory to order prior to demand occurs. The uncertainty of demand leads to the decision point to select ordering quantity such that customer demand will be less than order, or demand will exceed the order). The balance between the excessive inventory and inadequate inventory is the theme of the newsvendor model. The lead time to source products also affects the decision. Considering the design attributes, product index, shopping mode, the firm decides the procurement quantity of a product to be Q units.

Hypothesis 1: The decision has a positive effect and the probability of demand will be less than or equal to Q units.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The operative decision problem can now be formulated as follows,

D = Uncertain demand
F_t = Forecast for a period, t
S = Sell price, (pair shoe)
C = Purchase charges,
V = Discount sell price
Q = Order quantity, decision variable (maximize expected profit, Q such that p($Q \leq D$)
$F(Q)$ = Probability of Q units to remain at inventory
C_o = Overage cost, (profit decreases loss by ordering one fewer unit, opportunity loss)
C_u = Underage cost, (profit increases by ordering one more unit).

Using per unit loss C_o, the expected loss on the Q^{th} unit = $C_o \times F(Q)$. Therefore, the expected gain on the Q^{th} unit = $C_u \times (1\text{-}F(Q))$. The probability that equals the critical ratio for Q^{th} unit, $C_o \times F(Q) = C_u \times (1–F(Q))$ gives, critical ratio, $F(Q) = C_u/(C_o+C_u)$.

For Normal distribution, $\Phi(z) = \dfrac{C_u}{C_0 + C_u}$

The ability to quickly respond to the changing customer expectations, and to manage procurement complexity will increase revenues. However, it requires an efficient decision-making process integrating past demand information, market analysis, customer response and flexible supply chain to maintain strategic procurement to deal with such complexity. Following steps describes the procedure:

Step 1: Select a product; assemble a dataset of product sale, S, and demand, D that are comparable (i.e., similar product). Obtain initial forecast and actual demand

Step 2: Evaluate A/F ratio (dataset)

a. Evaluate the average of A/F ratio
b. Evaluate the standard deviation of A/F ratio

Step 3: Predict a new sale forecast with a certainty. If new forecast is 90% confident, then smoothing constant, $\alpha = 0.9$, where $\alpha \in (0,1)$. Updated forecast is a weighted combination as,

a. $F_{t+1} = \alpha\left(D\right) + \left(1-\alpha\right)F_t$

Step 4: Set a Normal distribution function to predict the demand

a. Assess the mean and standard deviation as the following:
b. Determine the expected (demand) = Expected A/F ratio × Updated Forecast
c. Determine the standard deviation = Standard deviation A/F ratio × Updated Forecast

Step 5: Evaluate the critical ratio $\Phi(z) = \dfrac{C_u}{C_0 + C_u} = \gamma$

a. For forecast using Normal distribution, find z for Optimal Order Quantity Q, $z = \Phi^{-1}\left(\gamma\right)$

Step 6: Maximize profit, *convert z into Order Quantity, Q*, $z = \dfrac{Q-\mu}{\sigma}$

a. Therefore, $Q = \mu + z \times \sigma$.

The newsvendor model has extended theoretically in many directions, particularly pricing decision, inventory models safety stock level overbooking customers (Cachon & Terwiesch, 2012; Silver, Pyke, & Peterson, 1998; Nahmias & Olsen, 2015). The method is particularly important for multinational

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

companies, procure products from overseas with a long lead time. Certainly, e-commerce provides tools to control of marketing and distribution around the globe.

EMPIRICAL STUDY

A primary requirement of any e-commerce business is to employ a system to predict upcoming demand, manage orders and maintain inventory level efficiently. Procurement scheduling and capturing the main season sale demand are critical in e-commerce business because of the competition to get into the market first. Products that come to market later lose significant sales. In contrast, early availability in the market increases the profits. The prediction model uses the supply chain practices of a prominent online shoe seller (say, GW Inc.). GW is a European shoe designer, often sell a range 17 products, most of which are manufactured in South Asian countries. Although GW needs a long 10-12 weeks lead time to procure, their focus of online sale is mainly the order flexibility and cost-efficient delivery. As most online sellers, GW's priority is to balance the products procurement and customer order fulfillment for a target season. Extra products after the target season often sale with a discount price. Table 1 presents forecast and actual demand for GW's Shoe line data.

Table 1. GW's Shoes forecast and actual demand

Items	Cost	Forecast	Actual	Error	A/F Ratio	Rank	Percentile
Handmade Genuine Leather Men's	$29.98	319	119	200	0.373	1	5.88%
ROXDIA Spring Autumn Full Grain	$55.00	83	37	46	0.446	2	11.76%
Men Flats Shoes Luxury Brand	$52.85	122	72	50	0.590	3	17.65%
ZANVLLCHY 2017 Spring Summer	$43.86	122	78	44	0.639	4	23.53%
2017 Business Men Shoes Luxury	$42.16	43	28	15	0.651	5	29.41%
*Men Leather Flats High Quality (LF-HQ)**	$41.60	550	375	175	0.682	6	35.29%
JINTOHO Plus Size Men Flats Fashion	$37.99	72	50	22	0.694	7	41.18%
Fashion Men Shoes Luxury	$57.50	440	360	80	0.818	8	47.06%
Classical Men Dress Wedding Flat	$45.76	39	32	7	0.821	9	52.94%
Fashion breathable flats casual sh.	$42.36	47	56	-9	1.191	10	58.82%
LuoDiRam Brand 2016 Fashion Big Si.	$37.42	62	79	-17	1.274	11	64.71%

In the data collection phase, GW consults with designers and sale experts to project upcoming sales and use past sales data to revise main sale-season prediction. To better understand, GW's e-commerce supply chain procurement strategies and challenges, let's consider a particular item, Leather Flats High Quality (LF-HQ) men shoe, which is a newly redesigned product, target the upcoming summer selling season. Although GW's products are mostly casual and fashion shoes, some of the items are made for the professional sports. GW practices procuring items from the overseas supplier (i.e., shoe manufacturer) for the advantage of product variety, cost benefits, as well as their expertise to manufacture both casual, fashion and high-quality sports shoes. Due to the long lead time, GW must commit to procurement order prior to the target sale period. Therefore, strategic planning is a way for selecting uncertain procurement quantity long prior the target season despite their offerings and flexibility of shipment. GW's e-commerce inventory depends on the following hypothesis and steps,

Hypothesis 2: What is the upcoming forecast of LF-HQ and how many units should be ordered?

Following are the steps:

Step 1: Dataset and A/F ratio shows in Table 1.

Step 2: Item selected in the dataset, Table 1 as Leather Flats High Quality (LF-HQ) shoe:
Prior demand forecast = 550; New prediction = 800 units
With 60% weight (α =0.6) on new prediction, the weighted combination is given by,
(1-0.6) (550) + 0.6 (800) = 700 units

Step 3: Forecast is not random, but the A/F ratio is random
Set mean = Expected A/F ratio = 0.995
Set Standard deviation = 0.418
Expected (demand) = 0.995 × 700 = 697 units
Standard deviation (demand) = 0.418 × 700 = 293 units
Leather Flats High Quality show new forecast: Normal (697, 293)

Step 4: Assume Leather Flats High Quality shoe Cost
Each pair sells, S = \$41.6, purchase charges, C = \$23 and discount sell is V = \$17 per pair.
Loss: C_o = Cost – Salvage = C – V = 23– 17 = \$5
Gain: C_u = Price – Cost = S – C = 41.6 – 23 = \$18.6
Critical Ratio: $\Phi(z) = \dfrac{C_u}{C_0 + C_u} = \dfrac{18.6}{5 + 18.6} = 0.79$

Step 5: If the quantity ordered is Q, then with 79% probability,
Demand is Q or lower. Using z to find Q, (z = 0.84),

Step 6: The optimal quantity, $Q = \mu + z \times \sigma$. Therefore, Q = 697 + 0.84 ×0.84 = 943 units.

Above algorithm completes the necessary steps to forecast the LF-HQ demand for a target season. Note that a single sale forecast in e-commerce is not enough. The forecast has updated by integrating the potential variation of all sales, as (expected value and variation of A/F ratio) for all products in the e-brand.

CONCLUSION

This study employs a dynamic procurement models considering the market trend, updated design and customer demand in the online marketplace. The results of this study raise motivating theoretical and empirical points regarding the effect merchandise procurement and customer demand management. Although the results provide important guidelines for e-commerce development, it is practically impossible to perfectly match supply with the demand in due to the dynamic changes of customer expectations in e-commerce settings. The study has suggested that a newsvendor model is an effective tool for making such an instantaneous decision of ordering quantities when the quick response to the customer order is the main challenge in online marketplace. An efficient decision-making process integrating with customized information of the new demand information, contemporary fashion, customer response and flexibility in the supply chain are the key to advance e-commerce business.

E-commerce provides faster buying and selling procedure since the Internet provides more reach to customers for 24/7 buying and selling opportunity with no geographic limitations. E-commerce success includes performance issues, such as response time, international procurement lead time, or large demands in a small-time frame, order completeness and traceability of product delivery. Although a premium or express shipping service is available to major e-retailers, the delivery time may perceive a limitation compared to purchase in a store. Previous studies on the above-mentioned issues, however, have certain limitations. It is essential to be aware of the e-commerce challenges. The main challenge for sellers is the ability to analyze customer expectation, past sales, gathering information from the online pre-sales, the online market trend which are often difficult to track. The empirical analysis is shown here provided practical implications for sellers with basic information mainly collected from the internal excerpts and their projection for a product targeting the upcoming sales considering the design upgrade, and company's e-brand popularity, as well as the past sale data.

The greater part of the existing research focuses on tangible demand. Although it has become increasingly critical to deal with the variation of demand, safety stock, and unpredictability of the online business, much attention is needed to deal with the innovative products and faster customer response combined with competitive pricing and enhanced product quality. Furthermore, the sustainable resource planning, profit-maximizing and order fulfillment, and sustained seller reputation based on users' demographic, behavior, and expectations are remained to be investigated for the future.

Chapter 12
The Role of Social Commerce Components on the Consumer Decision-Making Process

ABSTRACT

Rapid changes in commerce, technology, and consumer behaviour are leading businesses to shift their online activities. The popularity of social media pushed online merchants to integrate these platforms into their online presence, leading to the rise of social commerce. Consumers' interaction and participation online create a massive amount of information. The use of social commerce components facilitates the interaction of consumers by sharing their experiences and learning from others' experiences. In this chapter, the authors look at how this process has impacts throughout the consumer decision-making process when making a purchase and suggests directions for future research.

INTRODUCTION

The increase of social media popularity is leading to the rise of social commerce (Lin, Li, & Wang, 2017; Wang & Yu, 2017). Social commerce is a subset of e-commerce based on social networks platforms. The possibility of interaction, the hallmark of social networks, is central to social commerce, allowing consumers to behave collaboratively by sharing information, recommending options and advising alternatives (Huang & Benyoucef, 2015). Research shows that consumers enjoy sharing their purchase information with their friends and contacts online and that they are receptive to following others' online recommendations when making purchase decisions (Chen & Shen, 2015). Often this type of informa-

tion is considered more reliable because it refers to an experienced user who has experience with the product (Kim & Park, 2013). Different factors impact on the willingness to be active online by providing recommendations and reviews. Website design in general, and social commerce features, in particular, have a high influence on consumers' participation online.

Despite the growing importance of social commerce, the impact of social commerce factors on consumers' purchase decision-making is under-researched (Chen, Lu, & Wang, 2017). In this vein, social commerce components are gaining scholars' and practitioners' interest. To the authors' best knowledge, although a few studies have researched the impact of social commerce components on consumer purchase decision process, there is a dearth of studies focusing on how consumers process the information acquired from the social commerce components and how this information impacts the purchase decision process (Chen, Lu, & Gupta, 2017).

In general, consumers share their opinion online about uncommon purchase experiences which they think may be helpful for others. For example, consumers may not share a "cigarette" purchase online with others unless they experienced an abnormal or a special situation in purchasing or in utilizing the product. In some cases, consumers share information about a purchase which have a high level of complexity. Other consumers will share purchases with a high-level of satisfaction (or dissatisfaction). Also, in the case of new products, early buyers may share their purchase experience since it is their first experience with this product. Thus, the information generated by consumers which will facilitate the purchase decision-making process of other consumers (Huang & Benyoucef, 2017), contributing to more accurate, faster decisions and, less effort.

Hence, this work aims at understanding both what drives consumers to share information online and the impact of such information in the buying decision process. We look at purchase decisions as cognitive behaviour. The chapter focuses on social commerce components to understand their impact on consumer purchase decision-making process. Chen and Gupta (2017) addressed the significance of ratings and reviews, recommendations, and communities and forums in improving the purchase decision. Ratings and reviews play a high role in minimizing consumers' uncertainty and consequently performing a high-quality decision by learning more about products' quality and attributes that other consumers had shared. The chapter aims to review the literature and propose directions for further research.

BACKGROUND

Social Commerce

Social commerce is a subset of e-commerce which may include two main types: a social network website that integrates commercial features enabling transactions and advertisement, or a traditional e-commerce website that includes social tools to enable social interactions. Central to social commerce are social networks and web technologies which allow users to acquire and share information and enable social commerce platforms to become an important learning platform. Social posts and information shared by earlier experienced consumers are learning sources for potential consumers; consumers are continuously learning from what other users are posting and sharing.

In the social media context, consumers' purchase decision-making processes are impacted by several factors such as website design, flow of experience, ease of technology, trust, and enjoyment (Lin et al., 2012; Parboteeah et al., 2009; Wu et al., 2016). The ease of use and learning facilitated by providing suit-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

able designed interfaces will result in easier acquisition of information by the user, which consequently leads users to execute a successful transaction (Lin & Lo, 2016).

Several studies use the flow of experience to capture the emotional motivation/reaction of users toward online shopping (Lu, Zhou, & Wang, 2009; Lin, Fernandez, & Gregor, 2012). Users will be more likely to sense enjoyment when they feel comfortable and confident during their shopping, and it may occur if consumers feel comfortable navigating and browsing online. Consequently, the enjoyment of consumers in their shopping experience and confidence using their online skills to overcome challenges during the shopping journey will raise positive feelings toward the task which will lead them to further interactions (Wu et al., 2016).

Social commerce provides consumers with an environment rich with information and experiences which enables them to learn and get knowledge on different interests. Consumers attempt to make an accurate purchase decision by relying on social commerce components and learning from others' experiences (Chen & Gupta, 2017).

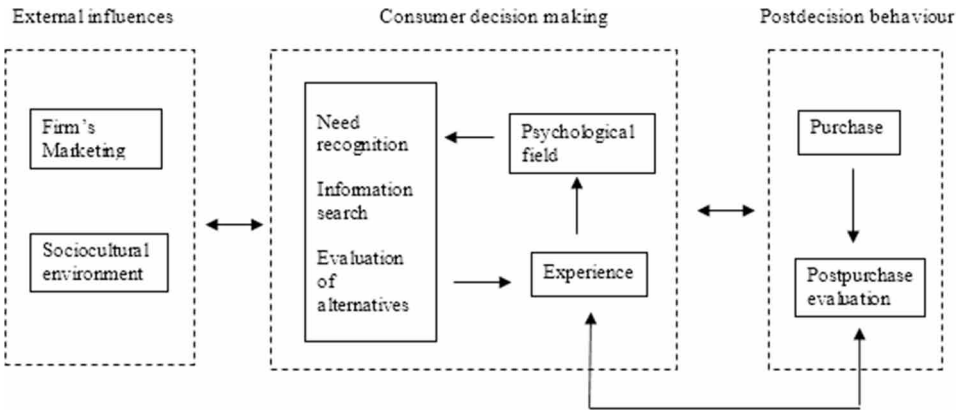
Consumer Decision Making Process Model

Consumer behaviour models provide an overview of the influences and processes involved in a given phenomena. Although they have limitations and should not be seen as aiming at providing an exhaustive picture of the complexities of consumer behaviour, models allow for a systematization of how and why consumers behave as they do.

Several models have been proposed to illustrate consumer decision making. Schiffman and Kanuk model of consumer decision making (Fig 1) has been used as a comprehensive frame of reference of the process and influences relevant for the understanding of the inputs, process, and output of consumer behaviour (Schiffman & Kanuk, 2007). The model includes three components: the input, the process, and the output.

The input component covers the external influences that impact consumers' behaviour, decisions, attitudes and values. These include marketing strategies and activities of companies (i. e. all the marketing mix decisions) and sociocultural influences.

Figure 1. A model of consumer decision making
Source: Soares and Malota (2008), p. 14



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The process component refers to how consumers make decisions. Psychological influences such as values, motivation and attitudes play a dominant role at this stage. There are three stages in this process: need recognition, pre-purchase search and evaluation of alternatives.

Finally, the output component of this model is concerned with post-decision behaviour, namely the purchase and post-purchase evaluation.

Extant research discussed different models explaining the online purchase decision-making process (for example Rad & Benyoucef, 2011; Chen *et al.*, 2015; Karimi, Papamichail & Holland, 2015; Karimi, Holland & Papamichail, 2018).

However, in general, the five-stage decision-making process model has also been considered useful to understand consumer behaviour online: need recognition, pre-purchase (information search and evaluation of alternatives), purchase, and post-purchase evaluation. Visual attention analysis has also shown that the decision-making process consists of stages (Zuschke, 2019).

Social Commerce and the Consumer Decision Making Process

With no prior aim of purchasing a product, consumers may recognize their need for a product while navigating online through social websites (Chen & Gupta, 2017). When a need is recognised, consumers may search for information and possible solutions for their problem. Consumers collect product-related information even when they are not planning to buy a product immediately.

Consumers go through several cycles during the information search stage (Karimi et al., 2018, 2015), these cycles are a result of formulation, evaluation, and appraise of information (Chen et al., 2015; Karimi et al., 2018, 2015). According to Zuschke (2019), consumers were found to switch between processing patterns depending on the task's complexity.

The information search process depends on the importance of satisfying the need, familiarity with available solutions and the amount of time available for the search. According to Beresford and Sloper (2008), decision strategies with high cognitive effort are more likely to be used when decision accuracy is prioritized over saving cognitive effort. Information search can be internal or external. Internal search is based on existing information in memory (quality, quantity, accuracy, relevance). External search is the information search beyond one's memory and comprises not only personal sources (friends, experts, salespeople) but also impersonal sources (advertising, internet). External search occurs when internal search is not perceived as sufficient for a confident decision and whenever the benefits of the additional information prevail over its costs. After the process of information search, the consumer should have a set of possible alternatives for satisfying his/her needs.

From a consumer perspective, the journey of gathering and evaluating information is a cycle aiming at making an adequate choice. According to Chen and Gupta (2017), consumers gather and evaluate information by learning from the social commerce components. During this stage, product alternatives are identified and evaluating criteria are determined (Karimi et al., 2015).

Choice/purchase is the stage of the buying decision process where consumers decide what to purchase in order to fulfil their needs and solve their problems. Payne, Bettman and Johnson (1993) concluded that decision-makers select a choice strategy as a result of a trade-off between accuracy and effort. Allen (2002) cited that Russo and Dosher developed the compensatory 'majority of confirming dimension' strategy (MCD). This strategy assumes that consumers who are confronted with multiple options consistently process all the available information in an attribute-wise and paired-comparison manner. According to Allen (2002 p.517), the rational choice theory depicted choice experience to be divided into two steps.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

"First, a chooser must anticipate future consequences associated with an array of current choice alternatives. Second, the chooser must consider or imagine what his or her future preferences will be for the currently anticipated consequences associated with the choice alternatives."

Finally, the last stage refers to the evaluation of the received product by consumers in light of their expectations, for example, in terms of quality, performance, delivery, etc. (Chen & Gupta, 2017). The post-purchase is considered as an influential stage in the social commerce mode, in which consumers may turn from being influenced to becoming a potential influencer (Rad & Benyoucef, 2011).

Hence, social commerce may have implications of all stages of the decision-making process.

Decision-Making Styles and Knowledge of Product

Research has shown that decision-making style and prior knowledge of the product are important for the pre-purchase stage. Karimi, Holland and Papamichail (2018) confirm that the whole purchase process duration varies and is correlated to the decision-making style of the consumer and the level of knowledge of the product. Earlier studies classified online consumer based on their decision-making style and knowledge of product (Karimi et al., 2015). Karimi et al. (2015) hold that each type consumers processes purchase decisions in a different manner. Consumers are classified into satisficers and maximisers based on their decision-making style. Satisficers are consumers who look for alternatives that are good enough (Karimi et al., 2015), rather than try to achieve an ideal outcome. Satisficers are critically selective when it comes to using and processing of information (Chang & Burke, 2007). On the contrary, maximisers are consumers who carry out an intensive search for information and browsing (Chowdhury, Ratneshwar, & Mohanty, 2009). They conduct an exhaustive search for all possibilities and analyse thoroughly the available information (Schwartz et al., 2002). Maximisers try to identify the best alternative. Schwartz et al., (2002) found that maximisers tend to rely on information about how others are doing as a way of assessing whether their chosen outcomes were indeed the best. It was also reported that maximisers engaged in more comparisons regarding their purchase decision (Schwartz et al., 2002).

The prior knowledge of the product was also found to have an impact on consumer online purchase behaviour (Karimi et al., 2015). The information search and information processing are influenced by prior knowledge of the product (Karimi et al., 2015). Prior knowledge of product make consumers more conscious of what they prefer, consider less information, and raise self-confidence (Karimi et al., 2015).

Social Commerce Components (SCCs)

Social commerce components include social media, social shopping, ratings and reviews, recommendation and referrals, and online social communities and forums in which information is produced and shared (Hajli, 2012a; Hajli, 2012b; Rad & Benyoucef, 2011; Hajli, 2013; Friedrich, 2015; Chen & Gupta, 2017; Chen et al., 2017).

Recommendations

Shadkam and O'Hara (2013) indicate that social recommendation refers to the use of social media to have and make recommendations on what to read, eat, see, buy and do. A social recommendation can be text, location, or a combination of photos and text (Chen et al., 2017). The customer tends to recommend

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

a product if s/he is satisfied (Andronikidis, 2009). Chang and Hsiao (2013) reported that the availability of the recommendation feature in social networks apps helps users to choose between alternatives. Consumers' recommendations and suggestions are important sources of information on social websites (Wang & Yu, 2017). Social media users and shoppers who had the real purchase experience are the main contributors to social recommendations on social media. Consequently, social commerce websites display such recommendations to potential analogous shoppers in characteristics of recommenders such as preference and social relations (Li, Wu, & Lai, 2013). According to Chen and Gupta (2017), consumers tend to share their experience in online community platforms and like to describe the experience more thoroughly. Thus, other consumers will have an advantage from the described experience and learn from it.

Virtual Communities and Forums

Consumers acquire various information using social commerce components to support their purchase decisions. Communities and forums are considered as product experience platforms that assist merchants and retailers in creating user-generated content that drives possible sale (Hajli et al., 2014). Communities and forums' members provide support for each other. Chen et al. (2013) argued that users' interaction and the mutual support between them will lead, in return, to trust in the network itself. Moreover, Hajli (2012b) found that such social commerce components increase consumer purchase intention by increasing trust and perceived ease of use. Online communities and forums constitute a rich source of information. Contributors and participants in communities and forums use text, photos, and even videos to share their experience and educate others. Thus, users can learn different dimensions of the product/service, such as attributes or practical use, easier in communities and forums (Chen & Gupta, 2017). Indeed, users' participation in communities and forum is related to their target product and interests. According to Chen and Gupta (2017), learning from communities and forums reduces consumers' demand uncertainty.

There is a wide variety of virtual communities and forums, hence it is necessary to differentiate between online communities. Online communities differ from each other in their structure, objectives, models and type of members/users. Therefore, it is more relevant for future research to study each type of online communities individually.

Ratings and Reviews

Ratings and reviews are original social commerce tools for both consumers and online merchants (Shadkam & O'Hara, 2013). Often, reviews have a short text format with some photos attached. Ratings typically are numerical ranging from low to high. In general, ratings and reviews are associated. Ratings and reviews enable consumers to exchange feedback regarding goods and services and recommend choices based on their personal experience and point of view. From a business perspective, social media tools assist them to integrate users' feedback into their websites directly. From the consumers' perspective, information provided by real shoppers and independent users has high credibility and is very useful for purchase decisions (Kim & Park, 2013). Such information provided in reviews will enable users to learn about product quality and increase users' confidence regarding produce performance/characteristics (Chen & Gupta, 2017) and reduce consumers' uncertainty. According to Chen and Gupta (2017), learning from ratings and reviews increase consumers' interest and increase the capacity of information processing.

Unlike recommendations and referrals which have only one direction (positive) of influence on consumers, ratings and reviews are characterized by two directions, negative and positive.

Understanding Information and Knowledge Sharing Processes in Social Commerce

Different theories have been used as underlying frameworks to understand consumer behaviour in social commerce. In this section, we present these theories and also identify approaches that can be useful to this endeavour.

Previous studies have mostly used the Theory of Reasoned Action (TRA) and Technology Acceptance Model (TAM) as two main theoretical backgrounds to studies in this area (Hajli, 2012b). TRA and TAM explain that the actual use of the system is predicted by the behavioural intention of the user to use the system. Moreover, the user's intention to use the system depends on the user's attitude towards the use of the system, which is determined by the user's perceived ease of use and perceived usefulness regarding the system (Friedrich, 2015). These models are useful to understand the adoption of social commerce but do not emphasize the process underlying the information sharing process.

The Trust Transfer Theory (TTT) has also been used in recent studies to understand the intention in social commerce, namely the role of trust towards members in social shopping intention and social sharing intention (Chen, Shen, & Chen, 2014). Trust transfer takes place when trust is transmitted from a known entity/person to another unknown in an association environment (Chen et al., 2014). The transfer process includes three parties, namely trustor, trustee and a trusted (third party). If a trustor has a strong belief in the trustworthiness of the trusted third party, such trust can be transferred to the trustee when there is a close relationship between the trustee and the third party (Chen et al., 2014). In particular, the trustee is called the target and the third party called the source of trust transfer, and trust can be transferred from different kinds of sources, such as individuals or a context, using communication or cognitive processes.

Finally, the social learning theory is a significant theory of learning and development, it is also linked to various concepts of conventional learning (Bandura, 1971). The theory includes some social elements. It highlights that humans can acquire knowledge of new behaviours and information by observation. In social commerce, buyers get social knowledge about the goods and services which interest them through browsing the information created by other buyers, this is known as the social learning process (Huang & Benyoucef, 2015). Social commerce components provide a good setting for shoppers to perceive others' behaviour. Consumers have access to social experiences and knowledge by participating in communities and forums, browsing reviews and ratings done by others, or bearing in mind recommendations in social networks (Huang & Benyoucef, 2015). For social learning to occur, social interaction between learners and role models is required (Chen & Gupta, 2017). Learning implies two different interaction processes, an external interaction when individuals interact with the surrounding environments (social, cultural and material), and an internal psychological process. According to Chen and Gupta (2017), consumer interaction behaviours with social commerce components are an external interaction process.

The constructive consumer choice process framework developed by Bettman, Luce and Payne (1998) considers that consumers are attempting to accomplish goals, what influences the information they attend to and how it is perceived or encoded, and what factors affect the heuristics consumers utilize to combine information and make a decision. A consumer making a decision has a goal hierarchy, often developed constructively on the spot, specifying the goals and sub-goals he or she must achieve. Consumers' goals for choice processing are maximizing the accuracy of a decision, minimizing the cognitive effort required for the decision, minimizing the experience of negative emotion while making the decision, or maximizing the ease with which a decision can be justified.

FUTURE RESEARCH DIRECTIONS

Understanding how consumers collect and acquire information is of extreme importance both from a micro-level and macro-level perspective. This process of searching for, learning and sharing information has implications throughout the five stages of consumer decision making.

Our review suggests a number of research questions for further research, such as: How do consumers process information during the pre-purchase process and prior to making their choice? How do ratings and reviews affect consumers' pre-purchase decision-making process outcomes? Since ratings and reviews are not structured or in an organized format, does the order and tidiness of information affect the acquisition of information and evaluation?

Merchants are considering different dimensions before investing in their online activities. It is essential to understand consumers' behaviour and factors facilitating the process of information acquisition and use. In addition, acknowledging the role of ratings and reviews is highly recommended due to the value of this type of information on different social commerce platforms. Therefore, focusing on these aspects by scholars may provide a clearer picture to improve the understanding of social commerce phenomenon. Our review suggests a number of research questions for further research, such as: How do consumers process information during the pre-purchase process and prior to making their choice? How do ratings and reviews affect consumers pre-purchase decision-making process outcomes? Since ratings and reviews are not structured or in an organized format, does the order and tidiness of information affect the acquisition of information and evaluation?

Research also shows that recommendations increase trust on members and consequently consumers trust on the network. In addition, it was reported that ratings and reviews increase trust in product and platforms. Thus, the process of learning from social commerce components has a link to consumers' trust. Therefore, future researches can be directed to study how learning can build consumer trust. Do rating and ratings and reviews impact consumers' decisions in the same manner regardless of consumers' decision-making style and prior knowledge of the product? Do consumers acquire information from ratings and review process the information in the same way? Do consumers follow different choice strategies when making their purchase choice on social commerce?

Consumers are learning from ratings and reviews, and these posts are valued because they are posted by consumers who had the purchase experience. It is very interesting to study if consumers will assess all posted ratings and reviews without taking into consideration the variety of different consumers' preferences? In regard to communities, it would be more applicable to studying the different types of online communities individually to understand better consumers' behaviour. Finally, future studies may focus on the motivation behind consumers' participation by sharing their experience through rating, reviewing or recommending a product they had purchased.

CONCLUSION

Social commerce components are tools for consumers' online interaction which impact the consumers' decision process. It is essential to study the impact of social commerce components for online commercial activities development. Online merchants and retailers attempt to influence consumers to share their purchase experience. The interaction of consumers impacts the purchase decision of other consumers. The pre-purchase stage of the decision-making process is the phase in which consumers gather and process

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

information. Consumers behaviour during the purchase decision-making process varies based on their decision-making style and prior knowledge of the product. That variation impacts the purchase process outcomes. In addition, the information acquired and processed has an impact on the process in general. A consumer can learn about the product and get knowledge to perform the best decision. Consumers always seek to reduce the effort and time spent to make a purchase decision. Thus, purchase experience shared socially will help consumers on their purchase task. Information gathered from ratings and reviews may assist consumers in building the product criteria, limits the number of alternatives, reduce the number of cycles needed to evaluate between products, and speed up the whole decision process.

Furthermore, studies highlight that relational ties are the main core of social media and the base for social commerce to expand. Thus, studies on social commerce have the social view of relationships that need to sustainable and transparent for the success of the business. Therefore, social information provides a supportive and rich content in which people are more likely to interact with each other for mutual benefits and further build strong relationships. The aim of this chapter is to contribute to the consumer behaviour literature in particular, and further contribute to information systems literature, by illustrating the information creation and sharing process and consumers' use of that information in social commerce platforms.

The managerial contribution of the study will be in providing insights for online merchants and practitioners on best online practices regarding website design and interaction tools, specifically what tools could be used and how such tools could help to achieve the required objectives. On the other hand, the study will provide a better understanding of distinctive online consumer archetypes and how these consumers behave on social commerce. Based on that, identifying each group may facilitate the targeting and online activities tasks to simplify consumers' decision-making process. From a marketing management point of view, it may contribute to designing more effective navigation and information sharing platforms.

KEY TERMS AND DEFINITIONS

Consumer Decision-Making Model: Graphic representation of the cross interaction between market, social, environment, and individual factors affecting the flow of decisions of consumers.

Online Social Interaction: The online exchange of ideas and preferences between two or more individuals which can take the form of a comment, like, or by sharing what others had posted.

Purchase Experience: The different dimensions in feeling, knowledge, and satisfaction that a shopper gains during and after performing a purchase.

Ratings and Reviews: The reflection of users' experience regarding goods and services. Ratings are usually presented in a scale from 1 to 5, and reviews are expressed in a text in which photos can be included.

Social Learning: Refers to acquiring new behaviour and knowledge by observing others, in particular individuals with high influence.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social Recommendations: Raising attention on product, place, or person to other users who intersect the social relation, characteristics, or interests of the recommender.

User-Generated Content: Information created by users of different online mediums to introduce their ideas and/or experiences aiming to educated or entertain others and shared publicly. This information could be in a text, photo, audio, or video format.

Chapter 13
Understanding User Social Commerce Usage Intention: A Stimulus–Organism–Response Perspective

Tao Zhou
School of Management, Hangzhou Dianzi University, Hangzhou, China

ABSTRACT

The integration of social media and e-commerce leads to the emergence of social commerce. Although previous research has examined social commerce user behaviour from multiple perspectives, it has focused on the effect of instrumental beliefs, such as perceived value, and has seldom examined the effect of emotional factors, such as sense of community on user behaviour. The purpose of this research is to draw on the stimulus-organism-response (SOR) model to examine the effect of sense of community on users' social commerce usage intention. The results indicate that both social support and service quality (stimulus) affect the sense of community (organism), which in turn affects users' sharing and participation intention (response). The results imply that service providers need to develop the user's sense of community in order to facilitate his or her social commerce usage intention.

INTRODUCTION

E-commerce has been developing rapidly in the world. A report indicated that about 533 million Chinese users have conducted online purchase, accounting for 69.1% of its internet population (CNNIC, 2018). In the US, this figure is about 80% (Pew Research Center, 2016). At the same time, social media sites such as Facebook, Twitter and WeChat have been integrated with e-commerce, which leads to the emergence of social commerce, such as F-commerce (Facebook). In China, Jingdong (JD), a leading e-commerce company, has cooperated with Tencent, which is the largest social networking company. Users can access JD to conduct purchase via WeChat, a leading social networking platform developed by Tencent. These examples indicate that social commerce has been attached importance by enterprises.

In the social commerce context, users interact between each other and exchange their opinions, ideas and experiences. This plays a great influence on users' behavioural decision. They rely on the comments, reviews and suggestions shared by other members rather than the information posted by online vendors to make their purchase decisions (Chen, Lu and Wang, 2017). However, prior research has found that users lack intention to participate in social commerce (Zhang, Lu, Gupta and Zhao, 2014) and share contents (Liang, Ho, Li and Turban, 2011; Chen and Shen, 2015). This may hinder the development of social commerce. A report indicated that 72% of online shoppers have never shared their purchase experiences (CNNIC, 2017). Service providers need to understand the factors affecting users' social commerce usage intention. Then they can adopt effective measures to facilitate user behaviour and ensure the success of social commerce.

The purpose of this research is to draw on the stimulus-organism-response (SOR) model to uncover the effect of sense of community on users' social commerce usage intention. The stimulus includes social support and community quality, which reflect the effect of community members and platforms, respectively. As users frequently interact between each other in social commerce communities, they may exchange social support, which reflects the advice, suggestions, empathy and encouragement. Social support including both informational and emotional support has been found to be a significant determinant of social commerce usage intention (Shanmugam, Sun, Amidi, Khani and Khani, 2016; Li and Ku, 2018). In addition, this research adopted three factors of system quality, information quality and service quality from the information systems (IS) success model to examine their effects on user intention (DeLone and McLean, 2004). These three factors reflect the community platform quality. The organism is represented by sense of community, which reflects a user's feelings of membership, belongingness and attachment to a community (Koh, Kim and Kim, 2003). Response includes sharing intention and participation intention, both of which have been examined as the social commerce users' behavioural variables (Zhang et al., 2014; Ko, 2018). We believe that SOR provides a useful lens to understand social commerce users' behavioral decision process, in which external stimulus affects the internal state that leads to user intention.

Previous research has examined users' social commerce usage intention from multiple perspectives, such as trust (Lu, Zeng and Fan, 2016a; Lu, Fan and Zhou, 2016b; Hajli, Sims, Zadeh and Richard, 2017), social interaction (Xiang, Zheng, Lee and Zhao, 2016; Zhang, Benyoucef and Zhao, 2016; Wang and Yu, 2017), and perceived value (Hu, Huang, Zhong, Davison and Zhao, 2016; Sun, Wei, Fan, Lu and Gupta, 2016; Chung, Song and Lee, 2017). However, it has mainly focused on the effect of instrumental beliefs such as perceived value and has seldom examined the effect of emotional beliefs on user behaviour. This may undermine our understanding of users' social commerce usage intention. Extant research has reported that an individual user's emotion is a significant determinant of his or her behaviour (Tsai and Bagozzi, 2014; Wan, Lu, Wang and Zhao, 2017). In this research, we examine users' social commerce usage intention from the emotional perspective of sense of community. When users interact with each other in a social commerce community, they may develop sense of community, which in turn affects their behavioural decision such as sharing and participation intention.

RESEARCH MODEL AND HYPOTHESES

Social Commerce Usage Intention

As an emerging model, social commerce usage intention has received great attention from information systems researchers. Due to the significant uncertainty and risk associated with social commerce, trust has been identified to be a significant factor affecting user behaviour. Kim and Park (2013) found that transaction safety, reputation and information quality affect users' trust in social commerce. Chen and Shen (2015) noted that social support affects trust, which in turn determines users' social sharing and shopping intention. Lu et al. (2016a) reported that institution-based trust affects users' transaction intention in social commerce marketplaces. Lu et al. (2016b) stated that social presence affects trust and a user's purchase intention in social commerce. These studies suggest that social commerce trust is affected by multiple factors such as reputation, social presence and social support.

In addition to trust, social interaction has also been examined in the social commerce context. As users conduct frequent social interaction, they may form close social networking relationships, which influence their behaviour. Wang and Yu (2017) argued that social interaction, which includes word-of-mouth (WOM) communication and observing other users' purchase, affects users' intention to purchase. Xiang et al. (2016) noted that parasocial interaction leads to users' impulse buying behaviour on social commerce platforms. Liu, Chu, Huang and Chen (2016) found that interpersonal interaction contributes to the flow experience, which reflects an optimal experience in social commerce. Zhang et al. (2016) stated that interactivity affects relationship quality, which in turn determines users' brand loyalty in social commerce. From these results, we can find that social interaction is a significant determinant of users' social commerce usage intention.

Previous research has also explored the effect of social support on user behaviour in the social commerce context. Liang et al. (2011) reported that social support including informational support and emotional support affects relationship quality and users' social commerce behaviour. Bai, Yao and Dou (2015) found that social support helps mitigate both product uncertainty and seller uncertainty, which in turn lead to social commerce users' purchase behaviour. Sun et al. (2016) stated that social support as a factor of social climate affects perceived value and users' purchase intention. These results highlight the necessity to take social support into consideration when examining social commerce user behaviour.

As evidenced by these studies, social commerce usage intention has been examined from multiple perspectives such as trust, social support and social interaction. However, they have seldom examined the effect of emotional beliefs such as sense of community on user intention. This research tries to fill the gap by drawing on the SOR model as the theoretical base.

SOR

The SOR originates from environmental psychology and it has been used to explain the effect of environmental factors on an individual user's psychological state and behaviour (Mehrabian and Russell, 1974). The theory proposes that environmental stimulus (S) may affect a user's internal state (O), which in turn affects his or her behavioral response (R). To some extent, stimulus reflects an input, whereas response reflects an output. Organism reflects the internal process. In this research, we include both social support and community quality as the stimulus (Hu et al., 2016), which reflect the effect of community members and platforms, respectively. The organism is represented by sense of community (Zhang,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2010), which reflects a user's affective states such as membership, belongingness and attachment to a community. Response includes both sharing intention and participation intention (Zhang et al., 2014). Sharing intention reflects a user's intention to share his or her experiences, advice and recommendations with other members (Chen and Shen, 2015), whereas participation intention reflects a user's intention to visit and use a community (Xu and Li, 2015).

SOR has been widely adopted to examine user behaviour in information systems research. Li, Dong and Chen (2012) examined the effects of both utilitarian and hedonic factors on mobile consumption experience. Zhang, Lu, Wang and Wu (2015) noted that site characteristics affect customers' co-creation experience and their intention to participate in co-creation. Hu et al. (2016) suggested that website features and peers' qualities affect shopping value, which further affects users' purchase intention. Liu et al. (2016) adopted SOR to find that interpersonal interaction affects the flow experience, which in turn affects purchase intention. These studies indicate that SOR provides a useful lens to explain user behaviour. This research generalizes it to the social commerce context.

Social Support

Social support reflects an individual user's experiences of being cared for, being responded to and being helped by other members in a community (Liang et al., 2011). As noted earlier, social support has been identified to be a significant factor determining user behaviour in social commerce (Zhang and Benyoucef, 2016). In line with these studies, we measured social support with two factors: informational support and emotional support (Liang et al., 2011). Informational support reflects the recommendations, advice, and suggestions that help to solve the problems (Liang et al., 2011). When users receive valuable information from other members, they may feel the utility and develop a sense of community, which includes membership and belongingness. Otherwise, they may feel that the community is useless to their working and life, which may lead to their disappointment and low sense of community. In addition, informational support can alleviate uncertainty and increase users' trust (Chen and Shen, 2015), which may help improve sense of community. Liang et al. (2011) found that informational support leads to a user's better relationship quality with a community. Lin (2011) reported that instrumental support (similar to informational support) affects a user's network ties and commitment to an instant messaging community. Thus, we suggest:

H1: Informational support is positively related to sense of community.

Emotional support reflects the caring, empathy and encouragement expressed by other members to an individual user (Liang et al., 2011). Compared to informational support that represents a direct support, emotional support is an indirect support. When users are in negative moods such as frustration and depression, they expect to receive emotional support from other members. The emotional support such as caring and encouragement may help relieve users' moods and facilitate their belongingness and attachment to a community. Lin, Hsu, Cheng and Chiu (2015) found that emotional support as a nurturant support affects community identification. Chen and Shen (2015) noted that emotional support affects a user's commitment to a community. Based on these results, we propose:

H2: Emotional support is positively related to sense of community.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Community Quality

In social commerce communities, users not only interact with other members, but also interact with the community platform. Thus, community platform quality as the stimulus may also affect their internal state. We draw on three factors of system quality, information quality and service quality from the IS success model to reflect the effect of community quality (DeLone and McLean, 2004).

System quality reflects the access speed, navigation and visual appeal of a community (Kim, Xu and Koh, 2004). System quality may form a user's initial impressions toward a community. When a community has fast access speed, effective navigation and an attractive interface, users may have good evaluations toward it and develop sense of community. In contrast, if the community has low system quality such as slow speed and a poor interface, users may feel that service providers lack the ability and integrity to provide quality platforms to them. They cannot develop belongingness and attachment to the community. Lin, Fan and Chau (2014) also found that system quality affects a user's sense of belonging to social networking sites. Thus, we suggest:

H3: System quality is positively related to sense of community.

Information quality reflects the relevance, timeliness and sufficiency of the information offered by communities (Kim et al., 2004). As information overload has become a common issue, providing relevant information to users based on their preferences is critical to ensuring a good experience (Hsu, Chang, Kuo and Cheng, 2017). This may help build users' trust in service providers and develop their identification to the community (Zhang et al., 2016). Similarly, timely and sufficient information may also demonstrate a service provider's trustworthiness. In contrast, users cannot build a sense of belonging to a community that provides low quality information to them. Thus, we suggest:

H4: Information quality is positively related to sense of community.

Service quality reflects the reliability, promptness and personalization of the services offered to a user (Kim et al., 2004). Users may expect to obtain reliable and personalized services when accessing social commerce communities. When this expectation is confirmed, they may become satisfied and develop a strong sense of community. In contrast, poor service quality may undermine a user's trust and his or her sense of belongingness and attachment. For example, if users wait much longer for the responses from communities, they may lack patience and drop their usage. Liang et al. (2011) found that service quality as a factor of website quality affects relationship quality, which includes trust, satisfaction and commitment. Thus, we state:

H5: Service quality is positively related to sense of community.

Sense of Community

Sense of community reflects an individual's feelings of relationship to a community (Koh et al., 2003). It often includes four factors: membership, influence, needs fulfillment and emotional connection (McMillan and Chavis, 1986). Membership reflects the feeling of belonging to a community. Influence reflects a user's feelings of control and influence over the community (Zhang, 2010). Needs fulfillment reflects

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

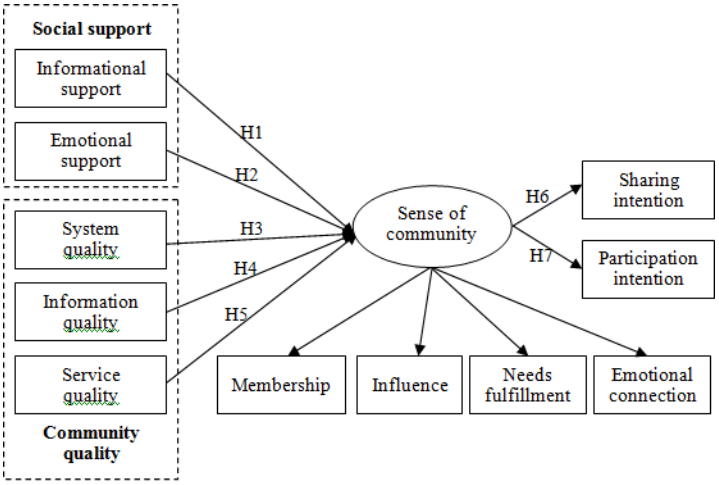
that users believe that a community will meet their needs. Emotional connection reflects the bonds developed among community members. Prior research has found that sense of community significantly affects social networking user behaviour (Zhang, 2010; Oh, Ozkaya and LaRose, 2014; Mamonov, Koufaris and Benbunan-Fich, 2016). We propose that it may also affect users' social commerce usage intention.

When users develop a sense of community, they may be motivated to actively share contents and participate in a community. They are proud of being a member of the community and perceive their value and influence in the community. In addition, they feel a sense of belongingness and attachment to the community. These feelings including membership, influence, needs fulfillment and emotional connection may facilitate their sharing and participation in the community. Mamonov et al. (2016) reported that sense of community affects users' contribution in social networking sites. Xu and Li (2015) noted that sense of belonging to a community affects community participation. Consistent with these studies, we suggest:

H6: Sense of community is positively related to sharing intention.
H7: Sense of community is positively related to participation intention.

Figure 1 presents the research model. Sense of community is a second-order factor, which includes four reflective factors: membership, influence, needs fulfillment and emotional connection.

Figure 1. Research model



METHOD

The research model includes eleven factors. Each factor was measured with multiple items. All items were adapted from extant literature to improve the content validity. Items of informational support and emotional support were adapted from Liang et al. (2011). Items of informational support (INS) reflect the advice and suggestions received from other members. Items of emotional support (EMS) reflect the caring, encouragement and empathy expressed by other members. Items of membership, influence, needs fulfillment and emotional connection were adapted from Zhang (2010). Items of membership

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(MEM) reflect the sense of belonging to a community. Items of influence (INFL) reflect a user's feeling of value and influence in a community. Items of needs fulfillment (NED) reflect that a community can meet a user's needs. Items of emotional connection (EMC) reflect the emotional bonds developed between members. Items of system quality, information quality and service quality were adapted from Zhou (2013). Items of system quality (SYS) measure the access speed, navigation and visual appeal of a community platform. Items of information quality (INF) measure the timeliness, accuracy, sufficiency and relevancy. Items of service quality (SER) measure the reliability, personalization and promptness. Items of sharing intention (SHA) were adapted from Chen and Shen (2015) to reflect a user's intention to share his or her experiences and recommendations with other members. Items of participation intention (PAR) were adapted from Zhang (2010) to reflect a user's intention to participate in a community.

These items were first translated into Chinese by a researcher. Then another researcher translated them back into English to ensure consistency. When the instrument was developed, it was tested among twenty users that had social commerce experience. Then according to their comments, we revised a few items to improve the clarity and understandability. The final items and sources are listed in the Appendix.

Data were collected at a university campus. We believe that university students are an appropriate sample for this research because social commerce as an emerging business model is popular among young adults. The CNNIC report (2018) indicated that users that were between twenty and twenty-nine years old are the largest group (30%) of internet users. In addition, students represent a majority (25.4%) of internet users. These data suggest that university students are an important group of internet users. Previous research has also adopted university students as the sample (Sim, Tan, Wong, Ooi and Hew, 2014; Teo, Tan, Ooi, Hew and Yew, 2015; Wong, Tan, Tan and Ooi, 2015). Data were collected in September 2017 at an eastern China city, where e-commerce is more developed than other regions. We randomly contacted students in the university and inquired whether they had social commerce experience. Then we asked those with positive answers to fill the paper questionnaire based on their experience. We scrutinized all responses and dropped those with too many missing values. As a result, we obtained 339 valid responses. Among them, 59% of male and 41% were female. A majority of them (75.5%) were between twenty and twenty-nine years old. About one third (37.8%) of them have used social commerce communities for more than a year. The frequently used social commerce communities include WeChat, Sina Weibo, Dianping, and Meilishuo, which represent a few well-known communities.

We conducted two tests to examine common method variance. First, we performed a Harman's single-factor test (Podsakoff, MacKenzie, Lee and Podsakoff, 2003). The results indicated that the largest variance explained by an individual factor is 22.65%. Thus, none of the factors can explain the majority of the variance. Second, we modeled all items as the indicators of a factor representing the method effect, and re-estimated the model (Malhotra, Kim and Patil, 2006). The results indicated a poor fitness. For example, the goodness of fit index (GFI) is 0.473 (< 0.90). The root mean square error of approximation (RMSEA) is 0.173 (> 0.08). The results of both tests indicated that common method variance is not a significant problem in this research.

RESULTS

Following a two-step approach, we first examined the measurement model to test reliability and validity. Then we examined the structural model to test research hypotheses.

First, we conducted a confirmatory factor analysis to examine the validity, which includes convergent validity and discriminant validity. Convergent validity measures whether items can effectively reflect their factor, whereas discriminant validity measures whether two factors are statistically different. Table 1 lists the standardized item loadings, the average variance extracted (AVE), the composite reliability (CR) and Cronbach Alpha values. As listed in the table, most item loadings are larger than 0.7. Each AVE exceeds 0.5, and each CR exceeds 0.7. This indicated the good convergent validity (Gefen, Straub and Boudreau, 2000). In addition, all Alpha values are larger than 0.7, demonstrating good reliability.

To examine the discriminant validity, we compared the square root of AVE and factor correlation coefficients. As listed in Table 2, for each factor, the square root of AVE is significantly larger than its correlation coefficients with other factors, suggesting good discriminant validity (Gefen et al., 2000).

Table 2. The square root of AVE (shown as bold at diagonal) and factor correlation coefficients

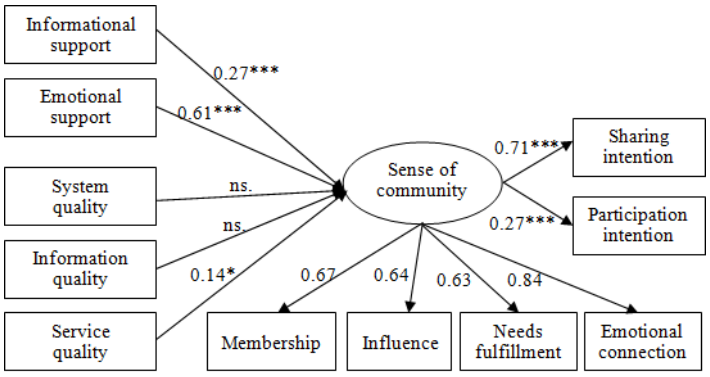
Figure 2. The results estimated by LISREL



(Note: *, P<0.05; ***, P<0.001; ns, not significant)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Second, we adopted structural equation modeling software LISREL to estimate the structural model. Figure 2 presents the results. Except H3 and H4, other hypotheses were supported. Four factors including membership, influence, needs fulfillment and emotional connection have high loadings on the second-order factor. Table 3 lists the recommended and actual values of a few indices. Except GFI, other fit indices have better actual values than the recommended values. The explained variance of sense of community, sharing intention and participation intention is 66.7%, 50.6%, and 7.5%, respectively.

Table 3. The recommended and actual values of fit indices

Fit Indices	chi^2/df	GFI	AGFI	CFI	NFI	NNFI	RMSEA
Recommended value	<3	>0.90	>0.80	>0.90	>0.90	>0.90	<0.08
Actual value	1.96	0.879	0.852	0.965	0.934	0.961	0.053

(Note: chi^2/df is the ratio between Chi-square and degrees of freedom, GFI is Goodness of Fit Index, AGFI is the Adjusted Goodness of Fit Index, CFI is the Comparative Fit Index, NFI is the Normed Fit Index, NNFI is the Non-Normed Fit Index, RMSEA is Root Mean Square Error of Approximation)

DISCUSSION

As shown in Figure 2, informational support, emotional support and service quality significantly affect sense of community, which in turn affects both sharing intention and participation intention. We did not find the effect of system quality and information quality on sense of community.

Compared to informational support, emotional support has a larger effect ($\gamma = 0.61, P < 0.001$) on sense of community. This suggests that users are much concerned with the emotional support when developing sense of community. To some extent, informational support is instrumental, whereas emotional support is affective. Users not only expect to obtain useful information from other members, but also expect to obtain emotional comfort to relieve their moods. When users receive the caring and encouragement from other members, they may build identification with a community (Lin et al., 2015) and form a strong sense of community. Mamonov et al. (2016) has found that social interaction is a significant factor affecting sense of community in the context of social networking sites. Our results indicated that social support also affects sense of community. Thus, service providers need to encourage users' exchange of social support including informational and emotional support in order to enhance their sense of community.

Among three factors of community quality, only service quality has a significant effect ($\gamma = 0.14$, $P < 0.05$) on sense of community. This indicated that users attach great importance to the services received from communities. Quality services such as personalized and reliable services may help build users' trust (Liang et al., 2011) and enhance their sense of community. For example, service providers have adopted location-based services to offer the personalized information and services to users based on their locations and preferences. This may help improve their sense of belongingness and attachment.

The results indicated that both system quality and information quality have no effect on sense of community. This is inconsistent with Zhang (2010), which found the effect of information quality on social networking users' sense of community in the US. The result may be explained for two reasons. First, our sample is composed of young adult users. They have relatively high self-efficacy and rich experience of using internet (Ifinedo, 2017). They are not much concerned with system quality when visiting a social commerce community. Second, our results found that informational support has a significant effect on

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

sense of community. This suggests that users paid more attention to the information received from other members rather than that from the community. They may feel that compared to the information offered by a community, the information offered other members is more helpful and useful to their working and life (Wang and Yu, 2017).

Sense of community has four high-loading factors: membership, influence, needs fulfillment and emotional connection. This suggests that it is appropriate to measure sense of community as a second-order factor. This is consistent with prior research (Zhang, 2010). Among these four factors, emotional connection has a relatively larger loading (0.84) on sense of community. This highlights the central role of emotional connection in sense of community. The results indicated that sense of community affects both sharing intention and participation intention. The effect of sense of community on sharing intention is especially strong *(*$\beta = 0.71$, $P < 0.001$). These results show that sense of community is a significant factor determining users' social commerce usage intention.

IMPLICATIONS AND LIMITATIONS

From a theoretical perspective, this research draws on the SOR model to examine the effect of sense of community on users' social commerce usage intention. As noted earlier, although previous research has examined social commerce user behaviour from multiple perspectives such as trust, social interaction and perceived value, it has focused on the instrumental beliefs and has seldom disclosed the effect of emotional beliefs such as sense of community on user behaviour. This research tries to fill the gap. The results indicated that both social support and service quality as the stimulus affect sense of community, which in turn determines users' sharing and participation intention in social commerce. These results advance our understanding of social commerce user behaviour. Future research may pay more attention to the effect of emotional beliefs such as flow when examining social commerce user behaviour. Second, we found that social support, which includes informational support and emotional support, has a significant effect on sense of community. The effect of emotional support on sense of community is especially strong. This suggests that sense of community as an emotional belief receives significant influence from emotional support. These results extend extant research, which has found the effect of social interaction on sense of community (Mamonov et al., 2016). Third, the results indicated that service quality of a community significantly affects sense of community. Thus, offering reliable and personalized services is helpful for improving sense of community. This enriches extant research, which has reported the effect of information quality on sense of community in the social networking context (Zhang, 2010).

From a managerial perspective, the results imply that service providers need to develop users' sense of community in order to facilitate their social commerce usage intention. On one hand, service providers need to create a supportive climate in social commerce communities. They can use incentives such as points to encourage users' exchanging social support between each other. They can also encourage opinion leaders to actively offer social support and act as examples. On the other hand, they need to improve the community platform and offer quality services to users. They may use location-based services to offer contextual information to users. This may better meet users' needs and help develop their sense of community. At the same time, service providers need to be concerned with information privacy and should obtain users' permissions before pushing location-based services to them.

This research has the following limitations. First, the sample is mainly composed of university students. Although they represent an important group of internet users, future research needs to generalize

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the results to other samples, such as enterprise employees. Second, we focused on the effect of sense of community on user behaviour and neglected the possible effect of other control variables such as user experience and satisfaction. Future research can examine their effects. Third, we examined users' sharing and participation intention in this research. Although behavioral intention is a significant determinant of actual behaviour, future research needs to test the actual user behaviour. Fourth, we conducted a cross-sectional study. However, user behaviour is dynamic. Thus, a longitudinal research may provide more insights into user behavioural development.

APPENDIX: MEASUREMENT SCALE AND ITEMS

Informational support (INS): Adapted from Liang et al. (2011):
INS1: When I encountered a problem, some people in the community would give me information to help me overcome the problem.
INS2: When faced with difficulties, some people in the community would help me discover the cause and provide me with suggestions.
INS3: In the community, some people would offer suggestions when I needed help.
Emotional support (EMS): Adapted from Liang et al. (2011):
EMS1: When faced with difficulties, some people in the community are on my side with me.
EMS2: When faced with difficulties, some people in the community comforted and encouraged me.
EMS3: When faced with difficulties, some people in the community listened to me talk about my private feelings.
EMS4: When faced with difficulties, some people in the community expressed interest and concern in my well-being.
Membership (MEM): Adapted from Zhang (2010):
MEM1: I feel that I am a member of the community.
MEM2: I have been in the community for a long time.
MEM3: I feel a sense of belonging to the community.
Influence (INFL): Adapted from Zhang (2010):
INFL1: I have a chance to provide advice or suggestions to other members of the community.
INFL2: Often there are some people that respond to my comments or the problems I posted in the community.
INFL3: I am an active member of the community.
INFL4: I care about what other members think of me.
Needs fulfillment (NED): Adapted from Zhang (2010):
NED1: In the community, my needs can be satisfied.
NED2: In the community, I can exchange with other members about the problems and get help.
NED3: It is worthwhile to spend time on the community.
Emotional connection (EMC): Adapted from Zhang (2010):
EMC1: I often discuss with other member of the community and enjoy the time.
EMC2: In the community, I and other members witnessed a few important matters.
EMC3: I have positive expectations toward the future of the community.
System quality (SYS): Adapted from Zhou (2013):
SYS1: The community runs smoothly.
SYS2: The community is easy to navigate.
SYS3: The community is visually attractive.
SYS4: The community quickly loads all the text and graphics.
Information quality (INF): Adapted from Zhou (2013):
INF1: The community provides me with up-to-date information.
INF2: The community provides me with accurate information.
INF3: The community provides me with information relevant to my needs.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

INF4: The community provides me with sufficient information.
Service quality (SER): Adapted from Zhou (2013):
SER1: The community provides reliable services.
SER2: The community provides personalized services.
SER3: The community provides prompt responses.
Sharing intention (SHA): Adapted from Chen and Shen (2015):
SHA1: I am willing to provide my experiences and suggestions when other members of the community want my advice on something.
SHA2: I am willing to share my own experience with other members of the community.
SHA3: I am willing to recommend this community to other people.
Participation intention (PAR): Adapted from Zhang (2010):
PAR1: If some people recommend this community to me, I will use it.
PAR2: I am willing to spend more time and effort on participating in the community.
PAR3: When I visit this kind of communities, this one is my first choice.

Chapter 14
Consumer Protection in Online Shopping:
An Investigation of Virtual Credit Card Awareness in Turkey

Emre Yildirim
https://orcid.org/0000-0001-8703-7743
Sakarya University, Turkey

ABSTRACT

The main purposes of this research are (1) to reveal the virtual credit card (VCC) awareness of online shoppers and (2) to prepare a to do list for managers and relevant institutions to provide a more secured internet shopping process by enhancing the trust perception of consumers. To this end, a structured questionnaire consists of three sections was designed and conducted during the period April-May 2018 in Turkey. The findings achieved show that online shoppers mostly attach importance to the recognition of the website, which means they seek trust in online shopping process. On the other hand, they mostly use credit and debit cards, which may make consumers encounter serious fraud issues. VCC usage is only 4.9% in general although VCC awareness is 55.1%. This low level of VCC awareness is associated with education level and the information provided by the financial banks.

1. INTRODUCTION

Today's increasing competitive market forces companies to keep pace with the technology, new trends and innovative changes to capture customer value (Berman, 2012). These attempts and investments are not a preference for companies, but a must when the consumers' power in terms of limitless choice among the variety of brands is considered. The main purpose is to be able to up to date; in other words, companies have to create new ways of doing business. Today, they succeed this by benefiting from the digital transformation. They can boost their sales, productivity and profits as well by serving more and more customers beyond the traditional ways (Matt et al., 2015). In this manner, every company wants

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

to cross the limits via digitalization, but this attempt heavily depends on the Information Technologies (IT) ability and the internet infrastructure.

Considering the internet infrastructure worldwide, Asia is the continent where the most internet users live with the rate of 49% according to the global internet usage statistics of Internet World Stats by 2018 (internetworldstats.com, 2018). On the second position, Europe comes with 16.8% and Africa follows with 11% on the third position. These statistics show that almost half of the internet users live in Asia. However, a different picture appears when the number of internet users is proportioned to the total population of the continents, also called as internet penetration. In this context, North America has the first place with the penetration rate of 95%, Europe comes second with 85.2% and Australia/Oceania is the third with 68.9% according to the new picture. These internet penetration rates indicate that the individuals at North America and Europe use the internet with a ratio over 80%.

Europe statistics by 2018 imply that the internet penetration throughout the Europe is increasing rapidly. According to the report prepared by Ecommerce Foundation, Sweden has the highest penetration rate with 99.7% while Switzerland is at the second position with 98.3% and Iceland is the third with the ratio of 98% (Ecommerce Foundation, 2018). On the other hand, Ukraine is at the bottom of the list with 66% when Turkey has a ratio of 68.4%, which means Turkey's penetration is one of the lowest ratios among European countries. This state of Turkey indicates that the country is supposed to cover a lot of ground to catch up with the level of the developed countries in Europe where the internet penetration ratio is remarkable over 85%.

The other issue closely related to internet penetration is online shopping which has a high importance in today's economic system. In this context, considering the European region statistics again, the most online shoppers live in the Netherlands and Switzerland with the ratio of 82% according to the report prepared by Ecommerce Foundation. Sweden is the second with 81% when Denmark and Luxembourg follow it with 80% (Ecommerce Foundation, 2018). As understood from here, internet penetration and online shopping differ widely across the EU. The highest internet penetration rates do not mean a highest online shopping volume. Then, the question, "why does not high penetration rates guarantee high online shopping volumes?" comes to the mind.

In response to this question, the background of online shopping has to be initially comprehended. Online shopping is a system that creates closer relationships by benefiting virtual infrastructure of the internet based on the exchange of products and money among producers and consumers, reduces the costs, and gives opportunity to consumers to reach the products/services easily and independently of time and space (Chang & Chen, 2008; Lee et al., 2010; Gomez-Herrera et al., 2014). Online shopping has many advantages for both producers and consumers. It makes easier the way of doing business via digitalization; it provides a limitless choice of products/services and comparison of them to get with a better price (Mokhtarian, 2003; Liu & Forsythe, 2010).

However, there is a heavy cost coming with this online system. As Yıldırım (2013) mentioned, the digitalization of the transactions between producers and consumers makes the virtual environment uncertain and risky. The reasons resulting from lack of face-to-face communication, not being able to touch and see the products physically (unobservability), the problems associated with delivery and payment transactions, and theft of personal and/or financial information pose an obstacle to the development of online shopping. In addition to these factors, cultural values may sometimes create barriers as well (Kueh & Voon, 2007). Consumers tend to avoid online shopping especially when they have high levels of uncertainty avoidance scores. They feel uncomfortable and do not prefer to purchase online because of the factors associated with uncertainty such as information asymmetry, and the possibility of third

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

parties' abusive intentions like information theft and financial frauds (Patterson, 2012; Petrova & Valles, 2012; Yıldırım & Barutçu, 2016).

In this manner, the importance of being secured financially stands out among online shoppers in Turkey where the uncertainty avoidance score is 85% (Hofstede Insights, 2019). Although there are some tools such as anti-virus software, security certificates (SET, SSL etc.) and secured http (Diker & Varol, 2013) to prevent the online frauds, none of them is found completely enough. Accordingly, other tools were needed, especially in the payment process, to make the price-sensitive consumers pay and purchase online (Valls et al., 2011). One of the tools developed to provide payment security is called Virtual Credit Card (VCC). This system works as a virtual reflection of the physical credit card without having a real limit. It is not physically available, and has a different card number. The most important feature of it is to allow the owner to make the limit zero when not in use (Oz, 2002; Erdağ & Batuman, 2006; Kaya, 2009). In this regard, VCC is thought to be a promising system in terms of consumer protection in online shopping process when considering the low level of Turkey's online shopping turnover and high level of uncertainty avoidance score.

In the light of all these information, it can be said that today's main problems are (1) how to provide a secured online shopping process to consumers, and (2) how to make them aware of the systems that provide security. Within this direction, this study is designed to (1) reveal the awareness of consumers through VCC and to (2) prepare a to do list for shareholders such as consumers, consumer agencies and other relevant institutions of the government and organizations based on the results to enhance the awareness of VCC. Providing a more secured internet shopping issue is thought to be significantly important in Turkey where the price-sensitive, uncertain-avoidant and conventionally purchasing consumers live.

2. BACKGROUND

2.1. Current State of Online Shopping in Turkey

As mentioned above, high levels of internet penetration rates do not guarantee the high volumes of online shopping. In the meantime, it is getting worse if the penetration level is low. Turkey is almost in the middle position with the ratio of 53% (Montenegro is the last with 13%), although it is one of the countries that have lowest internet penetration rates. Despite Turkey has shown a great progress when compared to last year's ratio, which is 29% (Ecommerce Foundation, 2017), there is still much to reach the level of the developed countries. The B2C turnover of Turkey, which is €12.5 billion, is also an evidence that supports the current state of online shopping where the UK is the first with 177.7, France with 93.2 and Germany with €93 billion. According to the report named as 'Household Information Technology Usage Report' released by TSI (Turkish Statistical Institute, 2018), the ratio of purchasing goods and services from the internet has increased from 11.8% to 29.3% in the last five years. Although this ratio increased approximately 4.5 point when compared to the previous year, online shoppers have to be encouraged to spend more in online shopping in order to reach a greater turnover.

The reasons why the online shopping turnover of Turkey is low can be explained with some reasons: low ratio of internet access, also called as internet penetration with 68.4%, the insufficient technological infrastructure, the problems caused by the e-retailer or e-seller and online shopping process, and other reasons such as trust issue and lack of experience of usage towards IT. Considering the ratio of purchasing goods and services from the internet, which is 29.3% by 2018 as mentioned before, also indicates the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

consumers who do not shop online. Stated in other words, the ratio of consumers who do not prefer to shop online can be expressed as 70.7%, which is significantly high. The reasons why consumers do not prefer to shop online in Turkey are explained in the report of TSI (2015) related to this topic. According to this report, the first reason not to shop online, which has a ratio of 81.2%, stems from the traditional shopping habits such as purchasing the products in person, like to see or touch the products and being loyal to the physical store. The latter is 'payment security and privacy concerns' with 44.2% and the third reason is distrust towards the process of receiving or returning goods with the ratio of 27%. As seen from here, excluding the first reason which is associated with traditionalism and regular practicing towards purchasing the products by seeing and touching more, the second most important factor that generates barriers towards developing the online shopping volume by enhancing the risk perceptions of consumers is payment security and privacy concerns. This concern leads consumer to feel financially insecure.

The privacy concerns of consumers in online shopping process generally stems from fraud and financial information theft that frequently occur. The state of unobservability and information asymmetry by the structure of the internet, which is attractive to malevolent third parties, enhances the risk perception of consumers (Tan & Thoen, 2010; Liu & Wei, 2003). The JavaScript codes uploaded to e-commerce sites by these malevolent individuals (Constantin, 2016), fake web sites, security vulnerability, virus attacks etc. are the some kinds of methods used for fraud (Aslanyürek, 2016). Preventing these kinds of fraud methods via websites and providing a more secured online shopping process are the businesses of the managers of e-commerce sites that directly interact with the online shoppers. These kinds of websites try to prevent the information leakage in the virtual environment by using tools such as anti-virus software, security certificates (SET, SSL etc.) and secured http (Diker & Varol, 2013). Besides the software security, some systems that guarantee payment process are also used. For instance, online shoppers have the chance of paying at the door concurrently with the delivery. However, consumers generally prefer to use credit cards due to the advantages such as the ease of use and installment option (Zengin & Güngördü, 2013; Kahraman, 2016) in online shopping. The statistics of 'Online Card Payment Transactions' that were released by The Interbank Card Center (ICC, 2018) in Turkey also support this tendency of online shoppers. According to the statistics of the last three years, domestic and international use of domestic card transactions amounted to 68.8 million Turkish Liras (TL) in 2016, TL 98.2 million in 2017 and TL 95.8 million in the first three quarter of 2018 that indicates a rising graph over years.

The rise of credit card usage in online shopping over years reveals that consumers have to be protected more at the point of online payment. In the contrary case, consumers may be vulnerable and encounter problems such as fraud and financial information theft. These kinds of problems may negatively influence the attitudes of consumers towards the next online payment preference via credit cards. Regarding this issue, the problems that consumers encounter in online shopping were announced by TSI (2018) in the 'Household Information Technology Usage Report'. Considering the results of the report, 21.5% of the consumers who shop online encountered at least one problem in the online shopping process by 2017. The most encountered problem is the delivery of wrong or damaged goods/services with the ratio of 49.1%. After that, the delayed delivery comes with the ratio of 46.5% and technical failure during the ordering or payment process follows it with 20.1%. In addition to these, fraud issue that contains the misuse of credit card information has a ratio of 15%. This ratio shows significant increase when compared to last years, which is 10.6%. This rise displays that online shoppers are now under financial fraud risk so much that they cannot be overlooked.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.2. Online Payment Methods and Virtual Credit Card (VCC)

Consumers cannot give up using credit cards and debit cards in online shopping due to some advantages they offer such as the ease of use, installment options etc., and this increases the volume of the use of cards in online shopping. This intense card usage, which creates a very attractive environment for third parties, caused an increase in the number of card fraud cases based on stealing card information and this situation made the banks involved in the procedure as well. Banks assure the payment procedure via the system called as 3D Secure by sending a confirmation code to consumers' cellphones (Kaya, 2009). Since there appears the law "Debit Cards and Credit Cards Law" no. 5464, which holds the banks responsible for providing system security, and does not make the card holders responsible for the losses that may occur through the theft of card information (Uçar, 2015). In other words, the unjust treatments, which are likely to occur through the theft of card information in online shopping, have to be undertaken by the financial banks. However, not all online sellers use this system enhancing the payment security yet because it is not mandatory.

All these previously mentioned issues show that the security of payment procedure in internet shopping cannot be fully satisfied with the efforts of a single party. In other words, the way to increase security in payment procedure is to use more than one security technique at the same time. In fact, the security of the online payment process on the websites, which have security certificates, cannot be fully assured by the security of the banks with 3D secure. On the other side, the banks do not want to suffer from the weighty responsibility that was imposed by the Law no. 5464. With this purpose, banks serve another secured payment system called as 'Virtual Credit Card (VCC)' to their customers in order to secure themselves and respond to the requests due to the aforementioned advantages.

VCC is connected with the digital information of the physical credit card, and it is not physically available as a form of plastic card (Oz, 2002). In other words, VCC has no chip or magnetic strip. It can only be viewed online and there is no risk of loss or theft because the cardholder does not need to carry on it (Kaya, 2009). VCC corresponds to the same account number as the physical credit card of the customer; however, it has a different card number, expiration date and CVC code (Erdağ & Batuman, 2006). VCC can only be used for the purchases and other transactions made from the internet. The limit of VCC can be reset when not in use and it can be increased just before online shopping (Konuk & Yıldırım, 2012). Thus, it cannot be used in the physical shopping environments such as stores. Through the VCC, it is aimed to decrease and block the online card frauds based on credit card information theft in online shopping (Özgüven, 2011). The ability of consumers to determine the credit card limit as they wish in online shopping and to reset it when not in use minimizes the loss that may occur even if the card information is stolen by third parties. In such a case, it will be impossible to make a purchase with a zero card limit.

Although secure payment can be provided by VCC, it is seen that there are a lot of credit card fraud cases carried out with the stolen card information nowadays. It is thought that this is associated with the lowness of VCC awareness, and low usage as well. In other words, greater awareness in VCC leads to greater usage of VCC in online shopping by more consumers. Otherwise, low level of awareness will cause financial frauds to increase over time. In a study carried out by Konuk and Yıldırım (2012) at Sakarya province of Turkey, it was concluded that 63% of the participants who had the majority of education level as high school with 56.5% did not hear about the VCC before. In other saying, the ratio of the VCC awareness is only 37%. In addition to this, the ratio of VCC usage is only 26.8% inside this group. With reference to this point, it can be assumed that it is not enough to have only awareness about

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the VCC because according to results of the same research, the participants claimed that the banks did not provide adequate information about the VCC.

As can be seen from the results of the research of Konuk and Yıldırım (2012), low level of VCC awareness may cause low level of VCC usage. From different point of view, the way to increase the level of VCC usage is to raise the awareness of consumers about VCC. At this point, the research called as "Turkey Internet Measurement Research" done by IAB Turkey (2012) has rich content about the internet usage of Turkish consumers and VCC usage as well. According to the results of this research that represents the general internet profile of Turkish consumers who are primary school and high school graduate with a clear majority of 60%, VCC usage ratio is only 12.16% among the other online payment methods. Considering the payment methods, credit card usage leads the way with the ratio of 77.28%. On the other hand, VCC usage comes after the cash on delivery method (19.31%) and money order/electronic funds transfer (EFT) method (16.92%) as the fourth with this ratio. Another research conducted by Çetin and Irmak (2014) lays out that VCC usage is 28.1% among the other payment methods. This result is much higher than the results of IAB Turkey, but still not enough. One of the reasons to reach a higher VCC usage ratio is possibly the education level of the participants who have PhD degree in majority with the ratio of 66.2% in this research.

Consequently, the level of VCC awareness among Turkish consumers is seen low, and this negativity may bring significant losses in the future. The current condition of the level of VCC awareness clearly states that VCC should be used in online shopping more. The usage of VCC by more consumers through providing the high awareness will also decrease the pressure of the Law no. 5464 on financial banks, and prepare a more secured shopping process as well by benefiting the advantages of physical credit cards. Starting from this point, it can be put forward that making the consumers use VCC in online shopping process can be provided by raising the level of VCC awareness.

Considering the literature as a whole, this research is expected to answer the following questions:

1) Which factors do consumers consider in online shopping?
2) Which payment methods do consumers generally prefer and use in online shopping?
3) What are the reasons to prefer the relevant payment method?
4) What are the strengths and weaknesses of online payment methods?
5) Do consumers have any knowledge/awareness about VCC?
6) Which factors are important to be aware about VCC?

3. METHODOLOGY

The main purposes of this research are (1) to reveal the Virtual Credit Card (VCC) awareness of online shoppers and (2) to prepare a to do list for managers and relevant institutions to provide a more secured internet shopping process by enhancing the trust perception of consumers. In this general framework, in order to minimize the fraud issues especially during the online payment process and to protect the consumers from serious financial losses in online shopping procedure:

Purpose 1: To reveal the awareness of consumers through VCC, and to identify possible factors that reduce and/or block level of VCC awareness. In this context, it is aimed to;

- Determine the payment methods used by consumers in online shopping.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Reveal the levels of VCC awareness within these payment methods.
- Reach the main reasons by identifying the factors that reduce and/or block level of VCC awareness.
- Develop the possible factors that have the potential to enhance the awareness after identifying them.

Purpose 2: To prepare a to do list based on the results of the 'purpose 1' and to inform the shareholders such as consumers, consumer agencies and other relevant institutions of the government and organizations to enhance the awareness of VCC level to provide a more secured internet shopping process. In this context, it is aimed to;

- Provide information what VCC is, how it is used and what factors to be considered when using it.
- Raise the awareness of the public through VCC.
- Minimize the fraud issues that consumers may encounter during online payment process.

To this end, firstly, a couple of interviews with two academics and two experts from the field were performed to make revisions and to have a better understanding about the questions, which were planned to use in the survey. Some of the questions were gathered from the previous study of Konuk and Yıldırım (2012), and the interviewers determined the rest. After that, a structured questionnaire consists of three sections including the questions to measure the (1) online payment systems, (2) virtual card awareness and (3) demographic characteristics of the participants that were designed according to the findings of the interviews. The questionnaires were conducted via face-to-face interviews during April-May 2018 in Turkey and 325 questionnaires were gained via convenience sampling. After the elimination, 314 questionnaires were analyzed. This research employs the non-parametric statistical tests in order to reach the findings of VCC awareness. The reason to benefit from the exploratory research is to reveal the deeper insights about VCC when considering the lack of the VCC studies in the literature.

4. FINDINGS

Table 1 shows the demographic characteristics of the participants.

In this context, females are in majority with the ratio of 56.1%, and single participants are with the ratio of 58.9% as well. Considering the education level that is very important for this study, the participants who are high-school graduate are in majority with 48.7% that represents almost the half. Subsequently, graduate participants come with 30.6% and upper secondary comes after it with the ratio of 11.5%. The ratio of the participants from primary school is significantly low with 5.1%. Regarding the occupation, the participants are mostly from private sector with the ratio of 40.1%, and the participants who have no work come after it with 32.5%. Lastly, the income level shows that the major group is 1501-3000 TL with the ratio of 41.7%.

Table 2 represents the factors that are considered primarily in online shopping process. As can be seen from the table above, the most important factor that online shoppers attach is the recognition of the website with the ratio of 18.1%. Guarantee, return and exchange policies provided by the website come as the second one with 14%, and customer reviews appear as the third one with the ratio of 11.1%. Besides, payment options come as 4th with 10.9. Regarding the table as a whole, it can be stated that online shoppers mostly attach importance to feel secure in online shopping. They prefer to purchase

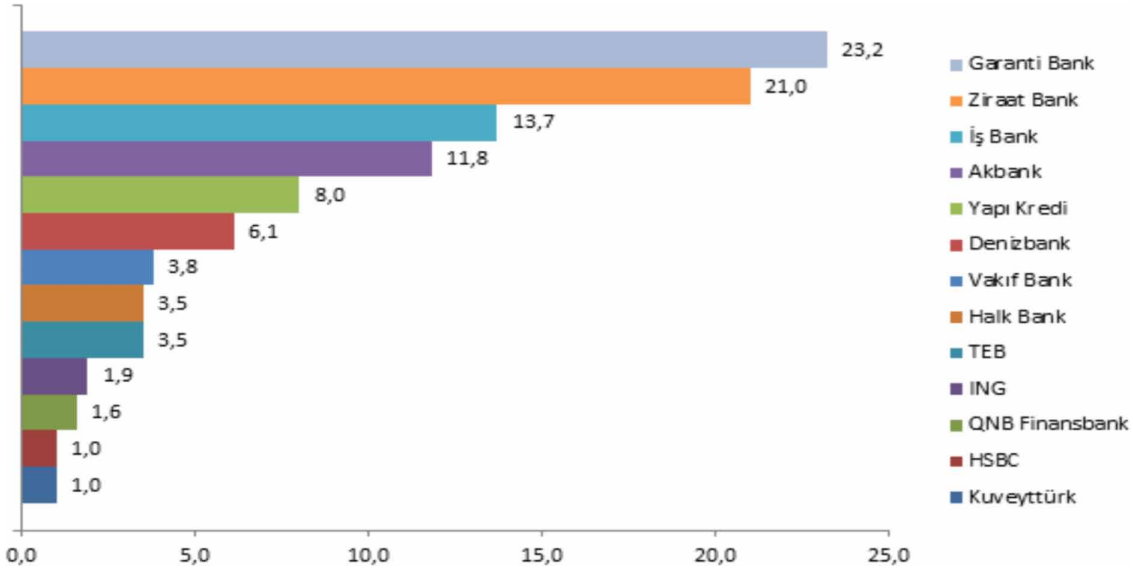
Figure 1. Preferred banks in online shopping



from the well-known websites, they want to see other customers' experiences about the website, and they want to see the security tools such as SET and SSL protocols not to be exposed to fraud issues. At the same time, they request different payment options; because, one option may not fit the customers' needs. When the website provides only one payment method, customers who are very sensitive to security may not purchase from there.

Figure 1 displays the bank choices of consumers in online shopping. As can be seen from the figure, the most preferred bank is Garanti Bank with the ratio of 23.2%, which represents almost one quarter of the participants. Ziraat Bank comes with 21% right after Garanti. These two banks lead the way among all the banks in this case. Additionally, Ziraat Bank and Garanti Bank are the most valuable brands among the banks, respectively (Brand Finance, 2019). On the other hand, HSBC, QNB Finansbank, ING and TEB do not have many consumers and not widely preferred as others have.

Figure 2 shows the payment methods that are generally preferred and recently used by online shoppers. Considering the first graph, credit card is the most preferred payment method with the ratio of 52.4%, which represents half of the whole. Secondly, debit card comes with 23.9% and in the third place; there is cash on delivery method with 13.5%. On the other hand, VCC choice is only 4.9% (only preferred by 22 participants) which shows a significant lowness. Regarding the second graph, it is seen that the levels of all payment methods except credit card are decreasing. This indicates that online shoppers cannot give up using credit cards in online shopping due to the aforementioned advantages although this payment method has several risks. Therefore, the importance of VCC comes into prominence again. However, the usage of VCC is only 3.5% as the last online shopping payment method. This may stem from the low level of VCC awareness as mentioned before.

Right after the Figure 2, Figure 3 represents the reasons why online shoppers prefer the relevant payment method in their last online purchase. In this context, the first reason to use the relevant payment method is the ease of use with the ratio of 39.1% in majority. This finding is mostly associated with the physical credit cards. The second reason is the payment security provided with 22.8% when installment

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Generally preferred and recently used payment methods in online shopping

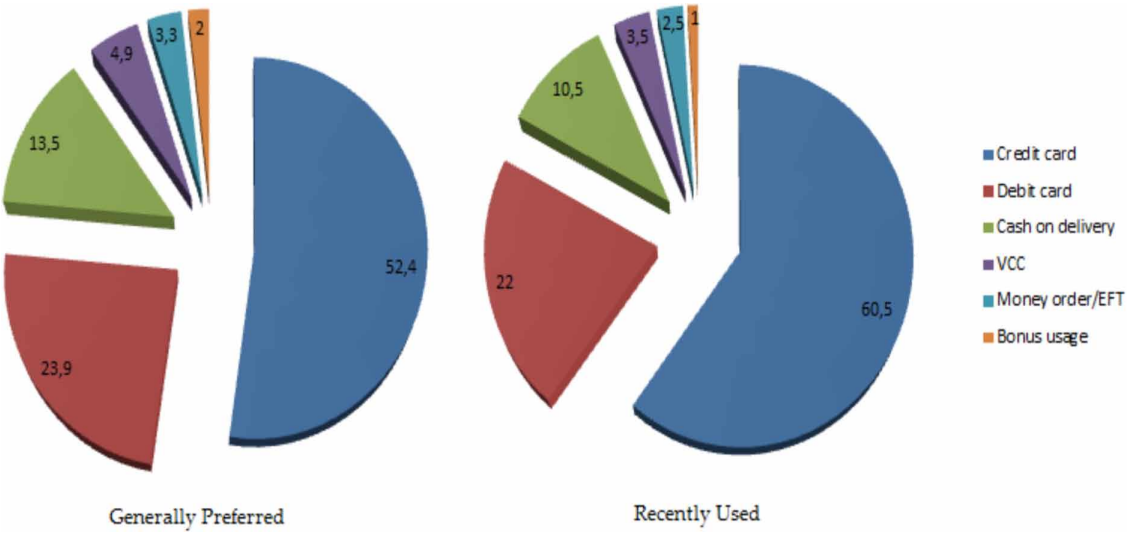


Figure 3. Reasons to prefer the recently used payment method

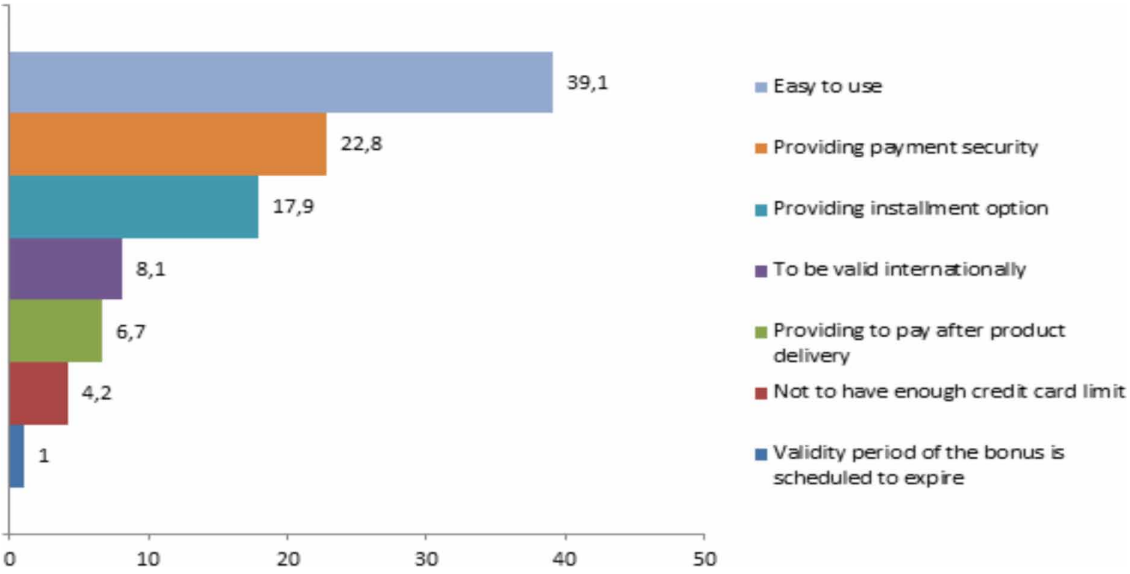


option is the third with 17.9%. The other reasons do not come into prominence with low ratios as these first three do. Moving from here, online shoppers mostly seek easiness, security and installment options in the purchase process.

Table 3 was generated in order to reveal the reasons associated with the payment methods to use in online shopping. With reference to this point, the reason 'easy to use' is mostly associated with credit card (67.5%) and debit cards (25%). This is not a surprise, because their usage is so simple by taking

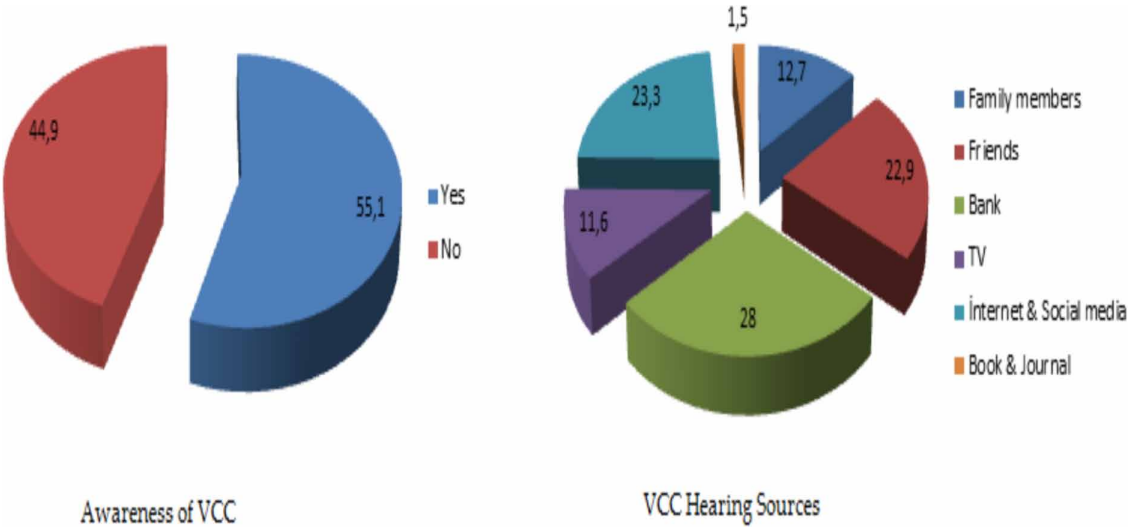
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Crosstabs of the recently payment method and the reason to prefer

	Credit Card	Debit Card	VCC	Money Order/EFT	Cash on Delivery	Bonus Usage	Total
Easy to use	135	50	1	3	9	2	200
Providing payment security	65	21	10	4	22	1	123
Providing installment option	77	12	3	-	1	-	93
To be valid internationally	27	11	2	1	1	1	43
Providing to pay after delivery	14	4	-	2	14	1	35
Not to have enough credit card limit	13	5	-	2	1	1	22
Validity period of the bonus	3	2	-	-	-	-	5
Total	334	105	16	12	48	6	

them out from the wallet/purse and typing the numbers on them into the online purchase screen. On the other hand, VCC is not found to be easy to use by online shoppers because of the working principle of it. Consumers have to log in their bank accounts, determine the limit and then they can purchase the order. This process prevents consumers from using VCC. The interesting point here is that 'providing payment security' is again mostly associated with credit cards (52.8%) although it has many fraud risks in online shopping. Consumers may not be aware of the risks they may encounter on the internet. 'Cash on delivery' is the second with 17.8% and debit card using is the third with the ratio of 17% although it has the same risks with credit cards. Considering VCC, the ratio is low with 8.1%, but the ratio is 62.5% when a self-evaluation is made. In other words, consumers who prefer VCC in their last online shopping use VCC because it provides payment security. Moving from here, VCC is also preferred because of the reasons which are providing installment option, to be valid internationally and easy to use, respectively.

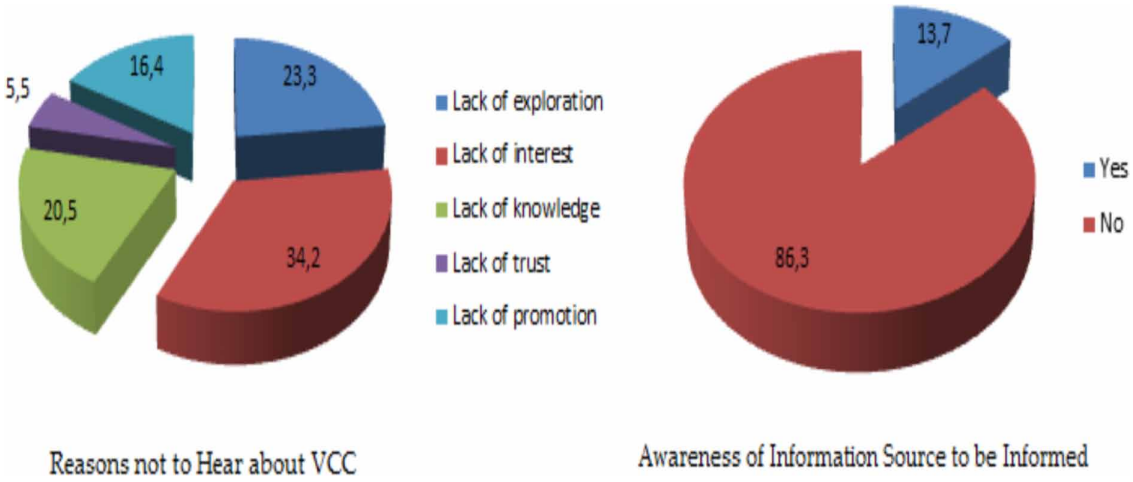
Figure 4. Awareness of VCC and VCC hearing sources



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4 shows the level of VCC awareness of online shoppers and sources of this awareness. In this context, consumers are mostly aware of VCC with the ratio of 55.1%. On the other hand, the level of consumers who do not know VCC is not low enough to be ignored with the ratio of 44.9%. Considering the sources, online shoppers mostly hear this payment method from financial banks with 28%, internet & social media with 23.3% and friends with 22.9%, respectively. In addition to these, family members (12.7%) and TV (11.6%) are important sources about VCC awareness as well. From this point forth, it can be stated that VCC has an average awareness level, which cannot be seen as enough for consumer protection in online shopping. Moreover, the share of financial banks, which have the first responsibility in case of fraud cases, is considerably low although it is the first source of information. Additionally, the level of internet & social media has to be increased by benefiting from the power of it to make the consumers be aware of VCC.

Figure 5. Reasons not to hear about VCC and awareness of information source to be informed



Considering the abovementioned graphs in Figure 5, the participants were asked to write the possible reasons why they have not heard about VCC so far, and whether they knew from which sources they can get information about VCC. In this context, the most encountered reason, why online shoppers have not heard about VCC, is the lack of interest with the ratio of 34.2% in majority. In other words, consumers are not interested in VCC, because they mostly attach importance to the ease of use of the payment method as mentioned in Figure 3. The second important reason is the lack of exploration with 23.3% and the third one is the lack of knowledge with 20.5%, which are also associated with consumers' interest. Besides, financial banks are also responsible for the low awareness, because they do not make promotions (16.4%) to give information about VCC. The second graph supports this finding as well. Regarding the second graph, most of the consumers with 86.3% do not know where they can get information about the VCC. These findings may be seen as the reasons why VCC awareness is not enough among online shoppers.

Figure 6 represents the awareness of online shoppers about VCC provided by their banks and whether adequate information is provided. Moving from here, consumers are mostly not aware of their bank's VCC application with the ratio of 64.3%. On the other hand, consumers who are aware of VCC state that the bank did not provide adequate information, which means consumers learn about the VCC from

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 6. Awareness of the chosen bank's VCC application and providing adequate information

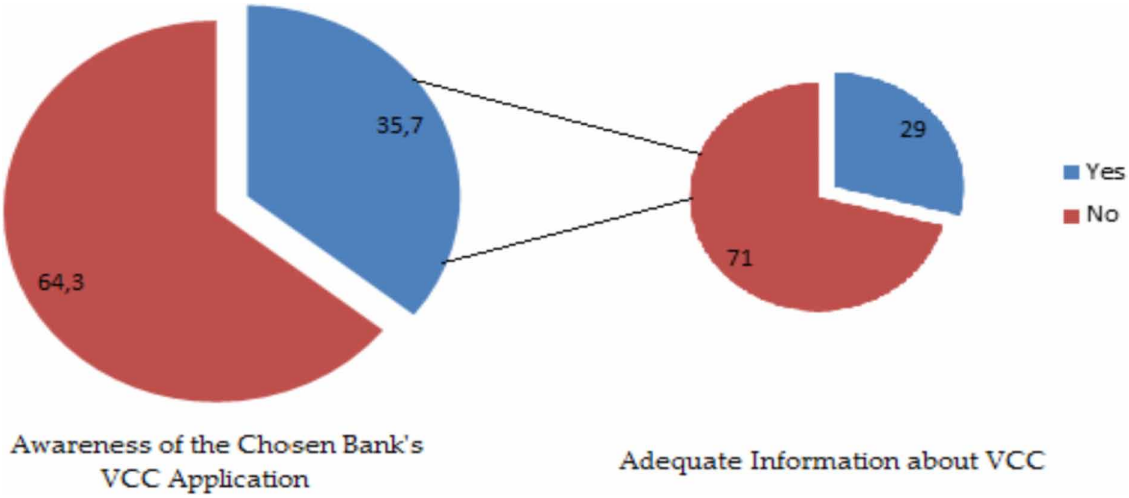


Table 4. Chi-square analysis through awareness of the chosen bank's VCC application and adequate information provided

		Adequate Information Provided?			Chi-square (sig.)
		Yes	**No**	**Total**	
Awareness of the Chosen Bank's VCC Application	Yes	86	26	112	,000***
	No	5	197	202	
	Total	91	223		

***sig.<0,001

other sources aforementioned before in Figure 4. Therefore, it can be re-expressed that the banks do not carry out their duties although their role is quite important for consumer protection in online shopping. This can be seen in detail below in Table 4.

Table 4 shows the crosstabs through awareness of the chosen bank's VCC application and whether adequate information is provided. In this context, online shoppers who are aware of their bank's VCC application also state that provided information about VCC is not enough (76.7%). In parallel, consumers who are not aware of the VCC application utter that no adequate information was provided (97.5%). In this regard, it also means that only 2.5% part of them was equipped with adequate information about VCC by their banks. It seems that there is a relationship between these two variables; therefore, chi-square analysis was conducted to test this relationship. As seen from Table 4, the significant level of chi-square analysis is under 0,001, which means this relationship is significantly supported by the data. In other words, as the banks provide adequate information for their customers, VCC awareness of the customer raises.

Table 5 indicates the crosstabs through awareness of VCC and education level. Considering the table, most of the online shoppers, who are primary and high school graduates, are not aware of VCC. More precisely, considering these education levels, 62.5% of primary school graduate consumers and 54.2%

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Chi-square analysis through education level and awareness of VCC

		Awareness of VCC			Chi-square (sig.)
		Yes	**No**	**Total**	
Education Level	Primary-school	6	10	16	,003**
	High-school	70	83	153	
	Upper secondary	26	10	36	
	Graduate	63	33	86	
	Postgraduate	8	5	13	
	Total	173	141		

**sig.<0,01

of high school graduate consumers are away from VCC awareness. On the other hand, a significant breaking point is seen with upper-secondary graduate consumers. 72.2% of these consumers have VCC awareness when graduate ones are at 73.2% and postgraduate ones are at 61.5% ratio. Moving from here, the group with the highest VCC awareness level is the consumers who have graduate level. It seems that there is a relationship between these two variables; therefore, chi-square analysis was conducted to test this relationship. As can be seen from Table 5, the significant level of chi-square analysis is under 0,01, which means this relationship is significantly supported by the data. That is to say, as education level increases, VCC awareness also increases.

CONCLUSION

Today's consumer purchase preference is mostly shaped around online shopping due to the developments in the Internet and Information Technologies. This virtual environment has its own rules and way of working. It has several advantages, but also disadvantages such as intangibility, fraud issues and so on. These issues make consumers more sensitive in online shopping procedure especially at the point of payment. It enhances the risk perceptions of consumers while decreasing the online purchase volumes for the danger of encountering serious financial problems. Therefore, the payment security has to be provided by relevant institutions and organizations.

In this research, it is concluded that online shoppers primarily consider the recognition of the website at the beginning of online shopping process. In other words, they do not prefer the websites that they are not acquainted with because they seek trust. Besides, consumers in online shopping also see the clarity of the policies that the website has and other customers' reviews as important factors. All these factors can be considered as the effort of the consumers to seek trust. Furthermore, they mostly prefer credit and debit cards as online payment methods. They prefer these payment methods due to some advantages, especially the ease of use during the process. Moreover, in the recent online shopping they used these payment methods, particularly the credit cards increasingly. However, these preferences as online payment methods throw online shoppers into the fire. As previously mentioned, they seek trust in online shopping but they do not know how to achieve this via payment methods exactly, because they have a misunderstanding about credit and debit cards provide payment security as well.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

In parallel, consumers do not mostly prefer VCC in their online shopping process, although the level of VCC awareness is surprisingly about 55%. More than half of online shoppers are aware of VCC, but fewer of them know its benefits. Accordingly, VCC awareness is not low enough to be ignored with 45%, because the ratio of consumers who use this payment method is only 4.9%. This may stem from the insufficient efforts of financial banks as an information source although they have the first responsibility in case fraud issues occur. Internet & social media and friends have almost the same percentage with banks, which means consumers seek information about VCC outdoor since banks do not do their part.

On the other hand, online shoppers are as guilty as financial banks, because they mostly attach importance to the ease of use of the payment methods. They seek trust but not interested in VCC; they have lack of knowledge and lack of exploration. In other words, it can be stated that online shoppers seek payment security in wrong places. The low level of awareness of information source that consumers can get information also supports this. The significantly high percentage with 86% shows that online shoppers are not aware of the information sources to be informed about the VCC. In addition to this, most consumers also do not know whether there is a VCC application in their chosen banks, because their banks did not provide adequate information about VCC. These results can be considered as the reasons why VCC awareness is not enough among online shoppers. As seen, this is a reciprocal procedure; therefore, consumers and banks have close responsibilities to decrease the level of online payment fraud issues. Moreover, education level is also important, because consumers who have low level of education do not have adequate information about VCC. Therefore, such problems can be solved via training programs provided by the relevant institutions.

This research also has some limitations. First of all, it has been tried to reveal the awareness of VCC. To this end, the questionnaire was designed in terms of descriptive statistics due to the lack of VCC studies in the literature. There are not any questions associated with the use of VCC, so further researches can be conducted in the light of the results of this research. The other thing is sampling method. Convenience sampling was used to gather data due to the lack of time and effort, and the study was carried out almost in two months. It can be extended over a period of time to enrich the results.

MANAGERIAL IMPLICATIONS

Considering the weighty responsibility imposed by the Law no. 5464 to financial banks, it can be stated that the only way for banks to wash their hands is to provide payment security for consumers in online shopping. According to the obtained results of the present research, there is a method providing payment security and half of the consumers know it. However, the results show that fewer consumers, who are aware of VCC, use this method. This proves the informing issue. Therefore, top organization of the financial banks called "Banking Regulation and Supervision Agency" should consider the results of this study, and make the banks give broad information about the VCC application. The banks can decrease the level of fraud issues all together and even prevent them. By doing this, they can create a trustworthy online shopping and protect themselves from the weighty responsibility of Law no. 5464.

Another relevant organization called "Information and Communication Technologies Authority" should also consider the results. There is a misunderstanding about VCC and consumers generally do not prefer to use it because of lack of interest, exploration and knowledge. In parallel, consumers mostly attach importance to the ease of use of the payment methods. From this point of view, regarding the relationship between VCC awareness and education level, when the usage of VCC is facilitated

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

via technological investments, consumers may be willing to use it more. In addition to this, the results provide important feedbacks to "Consumer Problems Association". If an increase can be achieved in VCC awareness and usage as well, the complaints stemming from the fraud issues in online shopping process can be decreased. This positive development will reduce the workload of "Consumer Arbitration Committees" which is one of the stakeholders in resolving complaints.

Consequently, the main purpose of both the institutions and the government is to make online shoppers use VCC in their shopping process. Almost there is no exact way to prevent financial frauds in the virtual environment, but it is possible to avoid. However, this is only possible when consumers know how to protect themselves against malevolent third parties. In this manner, VCC awareness can increase the use of VCC, and VCC usage can enhance consumers' trust perception especially at the point of online payment. Ultimately, all these developments contribute to the online shopping turnover of Turkey.

KEY TERMS AND DEFINITIONS

Bonus: Extra money which is too little and uploaded to the credit and debit cards through the shopping amount.

Cash on Delivery: The system enables to pay after taking the products.

Installment: The payment option that enables consumers to pay in parts.

Online Shopper: Consumers who purchase from the internet.

VCC Awareness: The knowledge level of consumers about virtual credit card.

Virtual Credit Card: The virtual version of the physical credit card with different numbers.

Chapter 15
Understanding Country Level Adoption of E-Commerce:
A Theoretical Model Including Technological, Institutional, and Cultural Factors

Punit Ahluwalia
University of Texas Rio Grande Valley, Edinburg, USA

Mohammad I. Merhi
Indiana University South Bend, South Bend, USA

ABSTRACT

This paper provides a theoretically grounded model of e-commerce adoption to explain differences in adoption rates among countries. The model extends the existing culture-policy-technology (CPT) framework to examine causal relationships between the technological, institutional, and cultural factors in order to examine country-level e-commerce adoption. Thus, interesting relationships among macro-level factors are hypothesized. The paper highlights the important of risk mitigating mechanisms or institutions to facilitate adoption of e-commerce in countries with high uncertainty avoidance. A call for empirical examination into country level adoption is answered by analyzing macro level data from 69 countries. The hypotheses are confirmed using PLS analytical procedures. The study is timely as e-commerce technology has now taken hold in several countries but its revenues in proportion to the overall total revenues remain low. The study is motivated by significant different in e-commerce adoption rates among countries. The paper makes significant contributions to literature and practice.

1. INTRODUCTION

In an ICT (Internet and Communication Technologies) enabled interdependent world, most countries consider e-commerce as a significant instrument for economic growth (Merhi & Ahluwalia, 2018; Zhu

DOI: 10.4018/978-1-7998-8957-1.ch015

& Thatcher, 2010). However, despite early promise, overall e-commerce revenues remain insignificant in comparison to the overall business volumes (D'Onfro, 2015; Edquid, 2017) and e-commerce adoption at the global level remains low (Commission, 2011; EUR, 2013; Postnord, 2014; Stambor, 2010). Research shows that e-commerce adoption rates among different countries and regions exhibit significant variations (Zhu & Thatcher, 2010; Statista, 2017). For example, in 2017 e-commerce sales accounted for only 2.2% of the total retail sales in India, 23.1% in China, and 16% in Korea (Statista, 2017). Disparities exist even within the same continent or the same group of nations (developed vs. emerging). For example, in Europe, online shoppers in the age group between 15 and 79 ranged from less than 40% in Italy to more than 80% in United Kingdom (Postnord, 2014). Statista (2017) reported that in 2017 the share of e-commerce sales in the total retail sales is 19.1% in UK, 12.6% in Denmark, and 7.9% in Germany. According to a study by Business.com in 2017, the e-commerce share of total retail sales in Japan 5.4%, France 5.1%, Canada 5.7%, Russia 2%, and Brazil 2.8% (Edquid, 2017). The question then arises, "what causes such variations?" Additionally, because of gradual and consistent accretion in e-commerce trade volumes in recent times, governments across the nation states are focused on improving their share in the overall global trade. Therefore, it is important to examine the important drivers of e-commerce adoption at a country level.

In the existing literature, studies focusing on macro-level determinants of e-commerce adoption are few; most of this research mainly emphasizes individual and organizational environments (Delone & Mclean, 2004; Grandon et al., 2011; Chiu et al., 2014). Although individual and firm level factors are important, they do not explain significant differences in e-commerce adoption among countries. Moreover, because of sampling constraints, the generalization of the results reported in the existing research that examine macro-level determinants of e-commerce adoption is rather limited. Most existing studies focus on adoption factors within one country (Stylianou et al., 2003; Yoon, 2009; Al-Hudhaif & Alkubeyyer, 2011; Jehangir et al., 2011). Also, a significant number of these studies are based on qualitative methodology (Aleid et al., 2009; Choudrie & Dwivedi, 2005). As a result, Tan et al. (2007) called for empirical research into cross-cultural and cross-country analysis of e-commerce adoption factors.

Moreover, most existing research examining e-commerce adoption by higher-order entities is exploratory and is not theoretically grounded, the only exceptions being Molla and Licker (2005b). They proposed the perceived e-readiness model based on the interactionism doctrine; but this model is targeted for organizations, not countries (Molla & Licker 2005b). Bajaj and Leonard (2004) proposed the CPT model targeted toward country-level e-commerce adoption in which they identified Culture, Policy, and Technology as the main first-order drivers underlying adoption. This paper draws from the CPT framework (Bajaj & Leonard, 2004) to propose a causal model that includes technological, institutional, and cultural factors as antecedents of e-commerce adoption. In doing so, we introduce increasingly pertinent factors (e.g. perceived efficacy of safety nets as an antecedent of e-commerce adoption) and drop factors that have become irrelevant (e.g. hard-wired vs wireless Internet). The present paper draws from the CPT framework yet significantly extends its propositions. With the passage of nearly 15 years since the CPT framework was initially published, there have been radical changes in the Internet and e-commerce milieu. With significant evolution in the quality, availability, and accessibility of wireless Internet as well as very high level of diffusion of wireless Internet, the user-perceptible differences between wireless and hard-wired Internet access have virtually disappeared. For example, the CPT framework considers hard-wired Internet and wireless Internet as separate technological factors. Additionally, the CPT model advances propositions based on logical arguments. This paper significantly advances the research of Bajaj and Leonard (2004) by grounding the present research in established theories. Even though building

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

upon the CPT framework, this research does not very strictly associate each of the factors included in the research model in a higher order factor. For example, the PEISN factor presented in the paper may be described as a cultural factor but also has significant policy implications. Yet another distinction between the CPT model and the research model presented in this paper is that we do not claim that our model provides comprehensive explanation of e-commerce adoption by countries. Unlike in Bajaj and Leonard (2004), we investigate a causal model to investigate the relationships among various factors of interest.

Now, we briefly introduce the factors included in our model, but expand their discussion in the subsequent sections of the paper. The technology drivers are captured in the composite index called "Maturity and Reach of Internet Technologies (MRIT)." MRIT includes dimensions such as accessibility, adequate bandwidth, diffusion of mobile networks, and implementation of security protocols. Research shows that governments are the primary agents for devising and implementing policies and creating channels for investments towards implementation of IT infrastructure (Picot & Wernick, 2007; Stoica et al., 2005); thus, government's focus on IT is a key driver of MRIT. Based on the Theory of Planned Behavior (TPB) and the Social Cognitive theory (Bandura, 1986), we argue that the perceived efficacy in using technology is an important driver of e-commerce adoption. We call this index "technological and entrepreneurial efficacy (TEE)." In order to mitigate the effect of uncertainty avoidance, institutional safety nets can safeguard the risks faced by the more vulnerable of the transacting parties. We also examine the role of perceived efficacy of institutional safety nets (PEISN) in facilitating adoption of e-commerce by people. To the best of our knowledge, this is the first paper that inquires into the effect of TEE, PEISN and uncertainty avoidance on country level adoption of e-commerce.

This paper makes significant contributions to research and practice. First, it contributes to the literature by examining the socio-technical determinants of country-level e-commerce adoption by developing a theoretically grounded research model that includes macro-level antecedents of e-commerce adoption. Second, this is the first paper that examines the role of safety nets as risk mitigating entities in e-commerce adoption. Third, the findings of this paper contribute to practice by suggesting the type and level of relationships of various factors of interest with e-commerce adoption. Fourth, the authors answer Tan et al. (2007)'s call for research by generating a significantly robust sampling frame comprising of sixty-nine countries in order to improve the generalizability of the findings reported in this paper. We make novel use of country-level data published by reputable organizations. The GFIT, MRIT, TEE, and e-commerce adoption indexes were published in the digital economy ranking study conducted by EIU (EIU, 2010). The PEISN data is sourced from the World Economic Forum (https://www.weforum.org/reports).

The paper answers the following research questions:

a) What are the relevant antecedents of e-commerce adoption at the country level in technological, social, and institutional domains?
b) What are the inter-relationships between various factors and country level e-commerce adoption?

The remainder of this paper is organized as follows. Section 2 provides background of the existing literature and the concepts examined in this paper. Section 3 describes the theoretical underpinnings of the research model and postulates different hypotheses examined in the paper. Section 4 provides information about the data used for empirical analysis. In section 5, the results are presented, and their implications are discussed. Lastly, section 6 concludes the paper by summarizing its important findings, highlighting its contributions, noting its limitations, and identifying opportunities for future research.

2. BACKGROUND

The units of analysis of most e-commerce adoption research are consumers and businesses. Kalakota and Whinston (1996) focus on consumers as they define e-commerce as "the delivery of information, products/services, or payments via telephone lines, computer networks or any other means." Zwass (1996) provides an organizational context to e-commerce by describing it as "the sharing of business information, maintaining business relationships, and conducting business transactions by means of telecommunications networks." Treese and Stewart (1998) define e-commerce more generally by stating that it is the "use of the global Internet for purchase and sale of goods and services, including services and support after the sale." While scholars have abundantly explored the individual and organizational perspectives, theory-based research into country level e-commerce adoption remains scarce. This paper attempts to bridge this gap in the current literature.

The e-commerce revenues continue to grow across the world because of explosion of Internet adoption (EMarketer, 2016). The development of reliable and advanced m-commerce technologies and the exponential increase in the use of smart devices is fueling this growth even more. Yet, the total e-commerce retail sales were a meager 7.4% ($1.671 trillion) of the total worldwide retail sales of $22 million (EMarketer, 2016).

Considering that e-commerce offers many benefits, the ratio of e-commerce sales to the total sales is likely to continue to increase in the coming years. Because of the widespread diffusion of the Internet, and unlimited availability of information to consumers, electronic markets are considered more efficient than the traditional markets (Calabrese et al., 2014; Blažic et al., 2015; Cui et al., 2015; Ghose & Yao, 2011; Wang et al., 2015). Consumers can purchase products without having to travel to the stores, saving them time and money; moreover, they have access to a wider selection of products. A comparison between B2C e-commerce and brick and mortar shopping reveals various convenience advantages associated with e-shopping; namely search convenience defined as "products easy to find and compare" (Kaufman-Scarborough & Lindquist, 2002), possession convenience, time convenience, and schedule convenience (Pavlou & Gefen, 2004). E-retail provides consumers with enhanced services; namely the ability to research and compare products, expanded choice in products, and ability to transact anytime-anywhere (Wu & Tsai, 2018). As the search costs are trivial and there is no restriction of geographical product differentiation, mass-produced physical goods are expected to exhibit none or at most minimal price differentiation, making electronic markets attractive to the consumers (Luo et al., 2007). According to one estimate, the year on year growth in e-commerce retail sales was nearly 25% in 2015 (EMarketer, 2016). Organizations tracking e-commerce sales have also reported significant diversity in growth rates among different countries: examples being 22.3% in Argentina, 12.2% in China, and 3.7% in USA (EMarketer, 2016). These studies have also reported significant diversity in percentage retail e-commerce sales in different countries. Table 1 shows the annual sales and the e-commerce share of total retail sales in year 2016 (Edquid, 2017).

Even though some researchers have looked into the causes of between-country divergences in adoption of e-commerce, there is a lack of theory-based empirical research that examines the relationships among the factors underlying such divergences. Tan et al. (2007) gave a call for research to examine intercultural and inter-country differences in e-commerce adoption. Most studies that examined country-level adoption of e-commerce are case studies based on data from single countries. Many of these are based on qualitative analysis of interview data. Nevertheless, these research studies are valuable because they

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. E-commerce sales as a percentage of total sales in 2016 (Edquid, 2016)

Country	Annual online sales	E-commerce share of total retail sales
China	$672 billion	15.9%
U.S.	$340 billion	7.5%
U.K.	$99 billion	14.5%
Japan	$79 billion	5.4%
Germany	$73 billion	8.4%
France	$43 billion	5.1%
South Korea	$37 billion	9.8%
Canada	$30 billion	5.7%
Russia	$20 billion	2%
Brazil	$19 billion	2.8%

illuminate significant drivers of country level e-commerce adoption. A succinct review of this literature is provided next.

Examples of studies focusing on e-commerce adoption in one country are: Saudi Arabia (Al-Hudhaif & Alkubeyyer, 2011), France (Brousseau, 2003), Taiwan (Chen & Barnes, 2007), China (Stylianou et al., 2003; Yoon, 2009), India (Vyas & Gupta, 2017) and Singapore (Wong, 2003). Some studies compared two or more countries as case studies: examples being USA and Saudi Arabia (Brosdahl & Almousa, 2013); USA and China (Tong, 2010); South Africa and Sub-Saharan countries (Molla & Licker, 2005b) and USA and Canada (Hong & Zhu, 2006).

Wong (2003) found that demographic structure, financial and legal institutions, physical infrastructure, human resources, and e-commerce policy initiatives impacted the adoption of e-commerce in Singapore. Molla and Licker (2005b) indicated that perceived organizational e-readiness (POER) and perceived environmental e-readiness (PEER) influenced e-commerce adoption in South Africa. Ho et al. (2007) found that Internet penetration, telecommunication investment intensity, educational level, and regional contagion affected e-commerce adoption in 17 European countries. Government policies, supportive legal environment, compatible socio-cultural infrastructure, ICT infrastructure, and culture differences also affect e-commerce adoption (Ferguson & Yen, 2006; Javalgi & Ramsey, 2001; Merhi & Ahluwalia, 2018; Zhu & Thatcher, 2010). Merhi and Ahluwalia (2015, 2016) argue that Internet connectivity, social and cultural environment and legal environment influenced e-commerce adoption at the country level.

Papazafeiropoulou (2004) examined e-commerce adoption in South European countries using the demand-pull and supply-push framework and made policy recommendations for better diffusion of technology in this region. Tan et al. (2007) examined organizational e-commerce adoption in China by using a perceived eReadiness Model framework earlier proposed by Molla and Licker (2005b). Although the study focused on organizational adoption, the eReadiness model includes external (to the organizations) factors such as Government eReadiness, Market Forces eReadiness, and Support Industries eReadiness. These factors are also relevant to country-level examination of the diffusion process. Tan et al. (2007) acknowledged that their study was conducted in one of the most advanced regions of China and gave a call for large, cross-cultural and cross country examination of the e-readiness model. Aleid et al. (2009) investigated the factors that influenced consumers' e-commerce adoption in Saudi Arabia. Based on the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

analysis of interview data, they reported availability, cost, and speed of broadband; the business process of delivery and returns; information about terms and conditions; security concerns; legal framework; government responsibility; and people's education as the important factors that affected e-commerce adoption in the country. Consumer trust, awareness of technology, technological infrastructure, e-maturity, education, and government policies have been identified as pertinent macro-level factors underlying e-commerce adoption (Mahmood et al., 2004; Pavlou & Gefen, 2004; Rose & Straub, 2001).

Most literature examining country-level e-commerce adoption comprises of exploratory studies, therefore they do not provide a cogent model or framework that could be applied in subsequent research. The first theoretically grounded model, named perceived eReadiness model (PERM), was proposed by Molla and Licker (2005b) which classified various pertinent factors of e-commerce adoption into organization and external factors. This eReadiness model presupposes the context as innovation adoption by organizations. The present study looks at the e-commerce adoption at a more general level and is not restricted to the organizational context. However, the theoretical reasoning underlying the PERM model can well be applied to the focus of the inquiry of this paper (Molla & Licker, 2005b). Particularly relevant is the interactionism doctrine which argues for collective treatment of multiple imperatives, that is, technology, managerial, organization, and environmental imperatives, in one framework. A framework focused on country-level adoption of e-commerce at a macro-level, and not constrained by the organizational context, is the Culture, Policy, and Technology (CPT) framework (Bajaj & Leonard, 2004). The CPT framework is not as explicitly grounded in theory as the PERM model[1], but is similar to the latter, except that it is focused on macro-level factors of adoption. The culture construct in the CPT framework identifies the dimensions of trust, corruption, and the patterns of communication. The policy factor includes the dimensions focused on general trade and on Internet usage and e-commerce. The technology factor comprises of three dimensions, namely, maturity of hard-wired telecommunication infrastructure, technical expertise within a country, and the level of wireless infrastructure.

We draw from the CPT model (Bajaj & Leonard, 2004) to frame the research model of the present study. Some changes in the CPT model may be necessary because of the evolution of different factors with the passage of time. For example, the wireless networks, devices, and applications have made quantum leaps in capability and diffusion from the time when the model was published. In the present times, users feel little difference in the reliability and bandwidth of Internet connections when using hard-wired or mobile Internet. Therefore, it may not be necessary to distinguish between hard wired networks and wireless networks in the context of e-commerce adoption as was conceptualized in the CPT framework. In this paper, we examine the impacts of two technological constructs, MRIT and TEE. As numerous articles reported the key role of government in implementation of IT infrastructure, we include Government Focus on IT (GFIT) in our model. Also, several articles emphasize that culture is a key factor why the adoption rates vary among countries. In particular, the exploratory studies that examined e-commerce adoption in developing countries highlight uncertainty and risk as significant concerns in the minds of potential adopters of e-commerce, especially in developing countries. Therefore, the role of uncertainty avoidance and perceived efficacy of institutional safety nets in affecting country-level e-commerce adoption is worthy of a rigorous investigation.

In e-commerce literature, researchers have only chosen, out of all other cultural dimensions of Hofstede, to examine the impact of uncertainty avoidance on e-commerce adoption. These studies have examined the influence of uncertainty avoidance based on primary data collected from individuals of certain countries. Belkhamza and Wafa (2014) examined the impact of uncertainty avoidance on e-commerce adoption using data collected from Malaysia and Algeria. They found that uncertainty avoidance

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

moderates the relationships between perceived usefulness, subjective norm, attitude, and intention to use e-commerce. In a study that investigated the impact of uncertainty avoidance and perceived risk on e-commerce in USA, Jordan, and India, Al Kailani and Kumar (2011) found that uncertainty avoidance and perceived risk negatively impact e-commerce adoption. Karahanna et al. (2013) collected data from 3500 consumers from 38 countries and found that uncertainty avoidance moderates the relationships between information quality and perceived usefulness, and between trust and e-loyalty.

Although these studies are important, they lack generalizability. We argue that in order to examine the impact of cultural impact on a phenomenon, country level data are required. For this reason, we investigate the impact of uncertainty avoidance on e-commerce adoption using Hofstede index.

Therefore, we include uncertainty avoidance in the research model of the present study. Finally, we borrow from the safety-net literature to posit perceived efficacy of institutional safety nets (PEISN) as an important determinant of e-commerce adoption. PEISN is an important factor especially in cultures where people associate greater risk with usage of e-commerce and presence of safety nets can instill the necessary confidence in people.

3. RESEARCH MODEL AND HYPOTHESES

This section explains the theoretical reasoning underlying different hypotheses examined in the present paper.

3.1. Government's Focus on IT and Maturity and Reach of Internet Technologies

The stakeholder theory provides a lens through which government's role in technology diffusion can be examined; political and economic philosophies and culture being other important factors. Governments' eminent role in diffusion of new technologies is widely reported in the literature (Papazafeiropoulou & Pouloudi, 2000). Japan and countries in Europe and North America designed and implemented technology policies dating back to 1970s (Papazafeiropoulou & Pouloudi, 2000). Freeman and Reed (1983) in their initial explication of stakeholder theory espoused the argument that organizations need to meet their goals by "balancing the conflicting claims" of its various stakeholders. The term stakeholder has been defined in several ways in the literature, ranging from a very restrictive to a very expansive view. The stakeholder theory changes the paradigm of organizational governance by shifting the focus from stockholders to stakeholders. Government's role in promoting technology and innovation can be classified into three technology policy paradigms, namely; market failure, mission mode, and cooperative paradigms. The "Market Failure" paradigm propounds that private markets are the best places for technology innovation, and the role of the government is restricted in the areas of defense and in times of market failure. The "mission mode" paradigm asserts a more participatory role of the government in which it acts as a complementary agent to the private sector by participating through grants and funding of universities and R&D organizations; the government does not compete with the private sector in this paradigm. In the "cooperative paradigm," governments can participate in technology development and innovation, especially for use of private sector (Bozeman, 2000). This framework explains different strategies adopted by different governments in promoting IT infrastructure in their respective countries.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Digital economy has become a significant contributor to the overall economic well-being of countries. In an increasingly interconnected world, countries are constantly competing with each other in order to increase their share in global trade and commerce. With digital economy becoming an increasingly significant platform for conducting trade and commerce, it is natural that governments would focus their attention and resources on putting in place adequate supporting ICT infrastructure in order to augment the access and quality of information technologies. In their study of diffusion of e-commerce in southeastern European countries, Papazafeiropoulou (2004) found that all governments supported the use of Internet and e-commerce.

Furthermore, governments are providers of efficient and unmediated services to its citizens through digital applications using ICT platforms. E-government applications have yielded expanded reach, faster speeds, and greater effectiveness in providing essential services to citizens (Merhi & Koong, 2013). As keepers of public interest, responsible governments are obliged to pay attention to reducing digital divide and to provide a fair technological platform for private sector to participate and compete. IT products and services now contribute significantly to the national assets of many countries. Research shows that governments make efforts to digitize the public sector not only to organize them better and make them more efficient, but also to offer indirect benefits by disseminating best practices to the industry and making people familiar with the technologies (Chen et al., 2006; Papazafeiropoulou, 2004). Thus:

Hypothesis 1: Government's greater focus on IT (GFIT) is positively related to, and is an antecedent of, the maturity and reach of Internet technologies (MRIT).

3.2. Maturity and Reach of Internet Technologies (MRIT), Technological and Entrepreneurial Efficacy (TEE) and E-Commerce Adoption

Implementation of an robust and reliable ICT infrastructure is an essential driver of e-commerce adoption (Okoli et al., 2010; Zwick & Dholakia, 2008, Mbarika et al., 2005). Similarly, the lack of telecommunication infrastructure is known to act as a barrier in the growth of e-commerce adoption (Kaba et al., 2009). Research shows that e-commerce depends on quality and effectiveness of Internet and mobile phone communications (Zwick & Dholakia, 2008) and computers (Elen et al., 2010). Higher broadband penetration, low prices of internet access, and good quality of network connections are likely to facilitate e-commerce adoption. Stylianou et al. (2003) found that even though the business climate in China was conducive to e-commerce adoption, it was hindered by inadequate technological infrastructure. Thus, ubiquitous availability of Internet access, reliable network connections, affordable prices, and implementation of adequate security protocols in the network and web technologies are fundamental drivers of e-commerce adoption. Thus:

Hypothesis 2: Maturity and reach of Internet technologies (MRIT) is positively related to, and is an antecedent of, e-commerce adoption.

Self-efficacy is defined as the belief "in one's capabilities to organize and execute the courses of action required to produce given attainments" (Bandura, 1997). According to social cognitive theory (Bandura, 1986, 1997), self-efficacy is considered as a form of self-evaluation that affects individuals' decisions about what behaviors to undertake, the amount of effort needed when faced with obstacles, and the mastery of their behavior. Therefore, individuals having low levels of self-efficacy are less likely

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

to perform a related behavior in the future than those with high degree of self-efficacy (Bandura, 1997). The IS literature has affirmed the importance of IT self-efficacy in adopting e-commerce (Bhattacherjee, 2000; Hsu & Chiu, 2004). These studies show that higher IT self-efficacy leads to greater e-commerce adoption. Molla and Licker (2005a) suggest technological preparedness and capability of organizations to adopt e-commerce. Aleid et al. (2009) suggested that people's education about e-commerce and lack of specialized IT companies and professionals were significant factors affecting e-commerce adoption in Saudi Arabia. Similar findings were reported in the investigation of e-commerce adoption by small and medium enterprises in Indonesia (Govindaraju & Chandra, 2011). They reported that number of educated people and people with IT skills, knowledge about the benefits of e-commerce, and the organization's way of doing business restricted the adoption. The foregoing explanation leads to the third hypothesis of this study:

Hypothesis 3: Technological and entrepreneurial efficacy (TEE) is positively related to, and is an antecedent of e-commerce adoption.

Gist and Mitchell (1992) suggest that analysis of task requirements, attributional analysis of experience, and assessment of personal and situational resources/constraints are the three important determinants of self-efficacy. The analysis of task requirements involves inferences about personal skills or qualities to perform an action. Attributional analysis is more about past experiences of performing similar tasks in the past. The third factor of personal and situation resources/constraints pertains to the assessment of the availability of different resources for performing specific tasks. We argue that MRIT (maturity and reach of Internet technologies) facilitates the analysis of task performance by individuals and overcomes personal and situational resources/constraints. Reliable Internet connections can ease people's concerns about the likelihood of interruption of online transactions before they are completed successfully. A sense of assurance about the security of Internet channel contributes to increased confidence that conducting online transactions do not involve financial and personal risks. Research shows that low levels of ICT diffusion can limit awareness about information and e-commerce technologies (Molla & Licker, 2005a). Based on the foregoing discussion, the fourth hypothesis can be stated as:

Hypothesis 4: Maturity and reach of Internet technologies (MRIT) is positively related to, and is an antecedent of, technological and entrepreneurial efficacy (TEE).

3.3. Uncertainty Avoidance (UA), Perceived Efficacy of Institutional Safety-Net (PEISN) and E-Commerce Adoption

Diffusion of Innovation theory asserts that the rates of diffusion are dependent on the characteristics of the adopters, the social network, the communication, and the characteristics of the innovation and the promoters. The characteristics of the adopters within a particular homogeneous group may be reflected by certain traits. Hofstede (1980) defined culture as a "collective programming" of minds of people within a society. The apprehension that their sensitive information may be stolen and misused is a key reason why many consumers feel anxious in using e-commerce. Uncertainty avoidance, a sense of discomfort with vulnerability and/or uncertainty, is a cultural construct (Hofstede, 1980). Research shows that security, privacy, and fraud are significant concerns in the minds of e-commerce consumers (Aleid et al., 2009). Uncertainty avoidance is defined as "the extent of feeling threatened by uncertain or unknown

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

situations" (Dorfman & Howell, 1997). In countries with high uncertainty avoidance, individuals tend to minimize ambiguity because they feel anxious in uncertain situations (Hofstede, 1980). In contrast, people in countries with low uncertainty avoidance feel relatively more comfortable with uncertain situations and can tolerate different opinions and behaviors.

Several scholars have criticized using aggregate measures of cultural constructs published by Hofstede (1980) for assessing individual level differences among different cultures (Bearden et al., 2006; Lim et al., 2006; Zhao et al., 2014). However, Hofstede's (1980) measures are appropriate to use for country-level assessment of cultures. (Smith et al., 2013). Researchers from many disciplines have replicated Hofstede's empirical results and used his cultural dimensions (Akinduko et al., 2017; Hallikainen & Laukkanen, 2018; Karahanna et al., 2013; Merhi, 2018; Merhi & Ahluwalia, 2015; Merkin, 2006; Mladenović et al., 2017). Unlike studies that are at the individual level at which Hofstede measures are often criticized, this manuscript correctly utilizes Hofstede to do a national level data analysis.

Uncertainty avoidance was found to negatively impact consumers' buying decision on Internet (Lim et al., 2004) and adoption of technology products (Bagchi et al., 2003). Typically, e-commerce puts the purchasers in a weaker position relative to the sellers, therefore invoking unbalanced risks against purchasers. Some examples of risk perceptions faced by e-commerce consumers are: receiving a product different from one expected, not receiving a product at all even after payment is made, not receiving product when it was promised, and breach of personal and financial information. Hofstede (1980) argues that individuals in countries with high uncertainty avoidance values are generally less willing to accept personal risk than those in countries that have low uncertainty avoidance index. People in high uncertainty avoidance societies are expected to avoid risky behavior (Kahneman & Tversky, 1979). Thus,

Hypothesis 5: Uncertainty avoidance is negatively related to, and is an antecedent of, e-commerce adoption.

Lyytinen and Damsgaard (2001) argue that the diffusion of innovation theory by itself is not adequate to explain the diffusion of information technologies in organizations because the technologies are subject to multiple forces, such as the influences of institutions, business context, and the economic and technological constraints. These forces, when exerting different pressures, can result in significant variations in diffusion of similar technologies. For example, considerable variations in the adoption of EDI technologies in Hong Kong, Denmark, and Finland were reported even though the motivations for the innovation were similar (Lyytinen & Damsgaard, 2001). The effectiveness of institutions in regulating fair trade practices and protecting the rights of consumers are significant factors in enabling adoption of innovation. For example, protection from credit card fraud emboldens people to conduct online transactions. Research shows that in general, people perceive e-commerce as more risky than conventional commerce (Chiu et al., 2014; Brosdahl & Almousa, 2013). Therefore, people's perceptions about the efficacy of institutions in delivering legitimate protection to them is an important determinant of e-commerce adoption. Presence of risk mitigating institutions can serve as coping mechanisms against perceived risks faced by consumers. Legal approach is the most common method of seeking justice; and effectiveness of laws is among the factors proposed in the CPT framework (Bajaj & Leonard, 2004). However, in many countries, seeking legal remedies is expensive and takes a very long time. People need remedies that are swift and which they can trust. For example, most retail businesses in USA state their return policies encouraging consumers to purchase the products, even for "just trying them out." Safety nets is defined in Wordnet as "a guarantee of professional or financial security" (WordNet2.1, 2005). Safety nets are

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

risk-shifting devices that are used in situations where normal-risks cannot be tolerated (Hovakimian et al., 2003). This paper draws from the safety-net literature to propose a new construct called Perceived Efficacy of Institutional Safety-Nets (PEISN) and empirically examines its relationship with e-commerce adoption. PEISN provides a sense of assurance that the online transactions are backed by institutions that are designed to safeguard consumers' interests by providing financial or professional guarantees.

As mentioned previously, PEISN is a perception about the effectiveness of safety nets that are hedging devices against risks associated with e-commerce. PEISN reflects people's assessment of the effectiveness of safety nets such as protection to buyers of online products and services. Uncertainty avoidance is also associated with risk; societies with greater uncertainty avoidance tend to minimize risks. Additionally, the societies with higher uncertainty avoidance prefer structured lives, and expect formal institutions to enforce stricter rules and laws covering most situations (House et al., 2004). Accordingly, people with higher uncertainty avoidance have lower acceptance of uncertainty and higher needs for structures, i.e. stronger formal rules and regulations (Lim et al., 2004). Consequently, people in societies with high uncertainty avoidance perceive a greater need for more effective safety nets, and they are likely to expect stricter standards for these institutions compared to people in societies with low uncertainty avoidance. Using the expectation disconfirmation principle (Oliver, 1977), the sixth hypothesis is now stated.

Hypothesis 6: Uncertainty avoidance (UA) is negatively related to, and is an antecedent of, perceived efficacy of institutional safety nets (PEISN).

Institutional safety nets such as efficient legal system protecting consumer rights can assuage the anxiousness of those who consider that online buying involve risks. Organizations like Better Business Bureau's (www.bbb.com) and TRUSTe (www.etrust.com) also provide structural assurances to customers by providing their reliability seals (Gefen et al., 2003). In a country where the legal systems are well developed, and enforcement mechanisms are efficient, individuals feel confident that their interests are protected. Research shows that potential and existing adopters of e-commerce are wary about consumer protection enforcement and laws governing e-commerce transactions (Aleid et al., 2009). People are reluctant to adopt an innovation unless they feel the confidence that their risks are contained (Kwast & Passmore, 2000). Because effective safety nets mitigate risks, the seventh hypothesis posits that:

Hypothesis 7: Perceived efficacy of institutional safety-net (PEISN) is positively related to, and is an antecedent of, e-commerce adoption.

Figure 1 summarizes the discussion in this section by showing all seven hypothesized relationships.

Figure 1. The research model

4. DATA

Country level secondary data consisting of seventy countries formed the initial sample for conducting the empirical analysis of the hypothesized relationships. Because the determinants comprise of macro-level indicators at the country-level, the sampling frame was formed by the data published by large, reputable organizations, which possess the wherewithal to collect data at a global scale. The data for GFIT, MRIT, TEE, and e-commerce adoption indexes were obtained from digital economy ranking study conducted by EIU (EIU, 2010). Table 2 shows different items comprising various indexes and their respective

Table 2. Factor indexes

Item		Weight
GFIT		
Government spend on ICT as a proportion of GDP		5%
Digital development strategy		25%
E-government strategy		20%
Online procurement		5%
Availability of online public services for citizens and businesses		15%
E-participation, based on the UN e-participation index		15%
	MRIT	
Broadband penetration		15%
Broadband quality		10%
Broadband affordability		10%
Mobile-phone penetration		15%
Mobile quality		10%
Internet user penetration		15%
International Internet bandwidth		10%
Internet security		15%
	TEE	
Educational level		20%
Internet literacy		20%
Degree of entrepreneurship		20%
Technical skills of workforce		20%
Degree of innovation (measured by the generation of patents and trademarks, as well as R&D spending		20%
Adoption		
Consumer spending on ICT per head		15%
Level of e-business development		10%
Use of Internet by consumers, assessing both the range of Internet features used by individuals and their online purchasing activity		25%
Use of online public services by citizens		25%
Use of online public services by businesses		25%

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

weights. The PEISN data is based on the survey items related to the effectiveness of ICT related regulatory environment and dispute resolution. These data are sourced from the "Executive Opinion Survey" of World Economic Forum (https://www.weforum.org/reports).

At this stage, data of 70 countries were available for further processing and analysis. The uncertainty avoidance index was drawn from the Hofstede cultural study (Hofstede, 1980; Hofstede et al., 2010). The uncertainty avoidance data for six of the seventy countries comprising the sampling frame was not available in the Hofstede's study, therefore separate procedures were adapted to impute the missing data for these countries. The six countries were Ukraine, Lithuania, Latvia, Kazakhstan, Azerbaijan, and Bermuda. Uncertainty avoidance indexes for Ukraine, Lithuania, and Latvia were directly available at www.Hofstede-insights.com. Indexes for Kazakhstan and Azerbaijan were imputed by using two-step triangulation. We explain the triangulation method next. Several cultural studies have been conducted after the publication of Hofstede's study. In the first step, the countries whose uncertainty avoidance scores were available in Hofstede's and whose scores were nearly equal to those of Kazakhstan and Azerbaijan in different studies were identified (House et al., 2004; Kaasa, 2016). In the second step, the uncertainty avoidance scores in Hofstede's cultural index tables were determined for the equivalent countries and these index scores were substituted for the respective countries, namely, Kazakhstan and Azerbaijan. No tangible uncertainty avoidance score was found for Bermuda in the literature, therefore it was dropped from subsequent analysis, leaving 69 countries in the sampling frame. Table 3 shows the descriptive statistics of the data set.

Table 3. Descriptive statistics

VAR	N	Mean	SD	Skew	Kurtosis	SE
GFIT	69	6.26	1.89	-0.08	-1.06	0.23
MRIT	69	5.13	1.96	0.03	-1.47	0.24
TEE	69	6.23	1.57	-0.07	-1.06	0.19
UA	69	64.64	22.55	-0.32	-0.49	2.71
PEISN	69	4.50	0.80	-0.26	-0.82	0.10
ADOPTION	69	5.71	2.17	-0.09	-1.36	0.26

5. EMPIRICAL ANALYSIS AND DISCUSSION

The hypothesized relationships were analyzed using partial least square modeling. The MatrixPLS package, a part of R statistical repository, was used to conduct the PLS analysis (Ronkk¨ o, 2017). The analytic results were cross-validated by using the SmartPLS software.

We used PLS because we have formative and not reflective measures (Lowry & Gaskin, 2014). Hair et al. (2017) offers rules of thumb for choosing between PLS-SEM and Covariance based-SEM. Hair et al. (2017) advise that it is best to use PLS-SEM when the data used in the analysis are secondary/archival, particularly single-item measures, and when the research objective is just to explain the relationships between exogenous and endogenous constructs. PLS-SEM is also the preferred method when sample size is below 100 and the constructs are formative (Hair et al., 2017). Our study meets all these criteria and we thus choose PLS-SEM.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The regression results of the bootstrapping analysis are shown in Table 4. The standardized path coefficients of the hypothesized relationships and the R^2 values of the endogenous variables are shown in Figure 2. Except for the relationship between uncertainty avoidance and e-commerce adoption (H5), all other hypothesized relationships were found to be statistically significant. The results and their implications are discussed next.

According to the first hypothesis (H1), government's focus on IT (GFIT) is a significant antecedent of maturity and reach of Internet technologies (MRIT) in a country. The MRIT construct includes access, quality, cost, and security dimensions of the Internet technologies within a country. In the contemporary digital global economy, the implementation and execution of public policies strongly influence IT capabilities and environment (Bhattacherjee & Sanford, 2006; Stoica et al., 2005). Many factors prompt increasing focus of governments on IT. This is because IT, directly and indirectly, is reported to contribute to the economic well-being of many countries (Van Dijk, 2003). Therefore, it is reasonable to expect that most governments would make conducive policies and work towards implementing and sustaining a robust IT infrastructure. Moreover, governments are expected to fulfill their fundamental responsibilities of framing and implementing policies for equitable participation of all stakeholders in the development and operation of IT infrastructure. Thus, government's involvement in diffusion of IT can be considered as a market regulator and as a provider of public good (Picot & Wernick, 2007). Governments are also direct beneficiaries from the affordances offered by IT applications as they offer many of its services (e.g. e-tax) to citizens using digital platforms in order to reduce costs, improve speed, and empower people. The empirical results confirmed hypothesis one.

The second hypothesis postulated that greater MRIT results in greater adoption of e-commerce (H2). The MRIT construct includes technological factors (broadband and Internet user penetration) that are essential for sustaining electronic transactions. Other factors such as cost and quality promote usage. MRIT also includes the dimension of Internet security, which is an important factor in users' adoption of e-commerce (Albrechtsen, 2007; Bones et al., 2007; Flavian & Guinaliu, 2006). The results show that MRIT is a strong driver of e-commerce adoption.

Technological and entrepreneurial efficacy (TEE) taps into educational, technical, and Internet efficacy, and entrepreneurial factors. Perceived efficacy is one's confidence in the capacity to successfully complete a task (e.g. make an online purchase). Cognitive relational theory suggests that people form a sense about their capability to perform actions by appraising their environment (Lazarus & Launier, 1978). Having access to the required technologies (i.e. broadband Internet, mobile wireless) at affordable cost and good quality (i.e. Internet security) lends confidence to the interested e-commerce users, thus augmenting their TEE. The results confirmed the positive relationship between MRIT and TEE.

TEE taps into educational and technical efficacy levels of people. Several studies have examined the role of efficacy in promoting use of IT at the individual level (Krueger & Dickson, 1994; McElroy et al., 2007; McFarland, 2001; Thatcher & Perrewe, 2002). Adequate confidence in security and quality of technologies is necessary before people feel assured to conduct e-commerce. This study also confirms the positive relationship between TEE and e-commerce adoption.

Uncertainty avoidance taps into the perception that people feel threatened by uncertain, unstructured situations, and ambiguity (Yoon, 2009). Individuals in countries with higher uncertainty avoidance index are more reluctant to engage with ambiguous situations (Hofstede, 1980). E-commerce transactions are characterized by presence of uncertainty because of spatial and temporal separation between buyers and sellers. This puts buyers in weaker positions compared to sellers, because in most cases, buyers complete their obligations before experiencing the purchased products. Therefore, societies with high

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

uncertainty avoidance are likely to be deterred from using e-commerce. The data failed to confirm the direct relationship between UA and e-commerce adoption. This result is in consonance with the findings reported by the earlier studies that show that the main effect of UA on ecommerce adoption was not statistically significant (Lim et al., 2004). The results show that PEISN mediates the path between UA and e-commerce adoption. The data support this mediated relationship (H6).

The practical implication of this finding is that effective institutional mechanisms can mitigate the consequences of uncertainty avoidance. For example, governments can set up effective and easy to use risk lowering mechanisms that can expeditiously arbiter disputes arising from e-commerce transactions. Industries can device their own mechanisms that serve as deterrents for dishonest digital firms. For example, in USA, the Best Business Bureau allows consumers to file complaints against businesses and provide information to other consumers about the complaint-data. At the firm level, companies can clearly state and honor hassle free return policies and provide easy to use communication methods (i.e. telephone, email, mailing address) that consumers can use to seek help and request redress. Legal remedies in most countries, especially in developing countries, are expensive and take very long to complete. In many countries, the existing laws may have been designed in the context of non-digital commerce. Setting up effective institutions that can act as safety nets can encourage people to adopt e-commerce.

6. CONCLUSION

This study investigates the causes of country-level differences in e-commerce adoption by examining specific macro-level drivers of e-commerce adoption. PLS analytic procedure was used to confirm the hypothesized relationships. This study contributes to the literature in many ways. This paper proposes a rigorous causal model to assess inter-country adoption of e-commerce. The model is solidly grounded in theory, drawing from the relevant theories, namely: the stakeholder theory, the e-readiness model, the theory of planned behavior, the PEISN literature, and the CPT framework (Molla & Licker, 2005a; Bajaj & Leonard, 2004; Ajzen, 2002). Thus, the paper makes significant contributions to the literature, and also answers an important call for inter-country empirical research into e-commerce adoption (Tan et al., 2007). This paper makes an important contribution to practice by proposing that setting up effective risk lowering mechanisms may encourage people to adopt e-commerce, especially in societies with high uncertainty avoidance. Finally, by using a robust data set comprising 69 countries, the paper improves the generalizability of its findings. This is a substantial improvement over the existing literature, which is mostly based on one country or at most a comparison of a few countries.

The findings of this paper offer important implications for policy makers. The research model provides a diagnostic tool for policy makers and governments to find out which specific areas need more attention in advancing e-commerce adoption. The ability to transact digitally provides organizations and consumers with numerous advantages such as cost savings, greater deficiencies, faster time-to-completion, more efficient inventories and supply chain management (Uzoka, 2008; Zhu & Thatcher, 2010). According to the findings of our study, policy makers need to consider their country's institutional and cultural environments. For instance, when people are reluctant to conduct Internet-based commercial transactions because of uncertainty avoidance, setting up effective safety nets can be beneficial in mitigating deterrent concerns of potential adopters. Industry and individual firms can device their own safety nets. The results show that government's role in implementing IT infrastructure in a country is a significant contributor to e-commerce adoption (total effect 0.68). The stakeholder theory explains different perspectives that the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

governments may take in implementing IT infrastructure in a country. In some countries, government owned organizations participate directly in ICT markets along with other private players (e.g. India); whereas in other countries governments confine their roles to policymaking and regulation (e.g. USA).

While this study makes many significant contributions to practice and research, its few limitations provide opportunities for further research on this important topic. Firstly, the findings are based on secondary data published by various organizations. Therefore, the findings reflect various indexes published by the source organizations. Studies of this nature have to depend on resourceful organizations such as the United Nations, ITU, EIU, and others for across countries data. Sourcing data from credible organizations lends integrity and authenticity to the findings. At the same time, the researchers are dependent on the composition of indexes and the times at which the data is made available by the sourcing organizations. For example, the cultural data published by Hofstede is several years old. The GLOBE cultural study (House et al., 2004) is more recent than the Hofstede study (Hofstede, 1980), but the data for this report was also collected prior to year 2000. A contemporary study comparable to Hofstede or GLOBE studies can provide updated scores of cultural factors. Moreover, data for all countries is not available in the Hofstede and the GLOBE studies. Therefore, uncertainty avoidance scores of five countries were substituted using other sources. We call upon additional research to examine inter-country adoption of e-commerce by improving these limitations.

Chapter 16
A Cloud Computing–Based Model of E-Commerce Adoption for Developing Countries

Ghada Refaat El Said
Management Information Systems Department, Future University in Egypt (FUE), New Cairo, Egypt

ABSTRACT

While e-commerce can contribute significantly to the economies of developing countries, challenges may include a lack of telecommunications infrastructure, low Internet and credit card penetration, lack of skilled professionals and insufficient delivery systems. Cloud computing offers a solution to most of these challenges, providing access to a low-cost, reliable and flexible internet-based infrastructure. However, there is little empirical validation of the adoption of cloud computing in e-commerce; to bridge that gap, the present study proposes a cloud-based model of e-commerce adoption. Based on a survey of leaders of 175 small, medium, and large ICT firms in Egypt, a developing country where e-commerce is expected to boom in the coming years, the proposed model empirically validates organizational, technical and contextual factors that would make e-commerce adoption more effective for business, governments and service providers.

LITERATURE REVIEW AND RESEARCH MOTIVATION

E-Commerce Adoption in Developing Countries

Several studies of e-commerce adoption in developing countries have emphasized the effect of contextual factors such as technological, economical, legal and financial infrastructures (Travica et al., 2002; Jennex et al., 2002) while others have looked at managerial and organizational factors affecting the adoption decision (Daniel et al., 2002). Molla and Licker (2005a, 2005b) developed the Perceived E-Readiness Model (PERM) for e-commerce in developing countries, integrating contextual and organizational factors. That model considers a number of internal organizational factors (e.g. organization's perception of e-commerce and its potential benefits and risks, managers' commitment, resources), as well as contextual

factors (e.g. government support, market forces, support industries' e-readiness) as important elements in e-commerce adoption. PERM has been validated as an effective e-commerce adoption model in a number of countries, including China (Tan et al., 2007), Bahrain (Ali et al., 2014) and Iran (Fathian et al., 2008). These studies highlighted critical issues for e-commerce e-readiness, including organizational features, technology infrastructures, IT availability and security environment.

However, all of the above studies are limited by their failure to address important organizational factors, such as Internet-based technology innovations currently adopted in these countries that can significantly impact e-commerce. In Egypt, e-commerce remains underdeveloped; according to the Egypt Business Directory (El-Behary, 2015), despite a 400% increase in Internet penetration between 2004 and 2015 to 31 million Internet users, only 2% of those users shopped online in 2015, and 80% paid on delivery. One key challenge for e-commerce in Egypt is low credit card penetration. In 2015, only 7% of Egyptians had a bank account, and only 7.6 million had a credit or debit card (El-Behary, 2015). This is expected to change during the next decade, with a massive increase in pre-paid and credit card penetration accompanying an e-commerce boom (El-Behary, 2015). The Internet contribution to GDP is projected to rise significantly to 1.6% of GDP in 2017 (Boston Consulting Group, 2012).

Other challenges obstructing e-commerce development in Egypt include a lack of technological infrastructure and the weak readiness of support industries like banking and tax and customs administrations (El-Behary, 2015). In similar countries, such as the Kingdom of Saudi Arabia, the lack of clear regulations and government support are thought to be key influences on e-commerce adoption (Al-Ghamdi et al., 2011). However, explanations of low e-commerce penetration within this fast-growing Internet population have not been empirically tested, and nothing is known about organizational, individual, contextual and technological factors affecting e-commerce adoption in Egypt.

Cloud Computing Adoption and E-Commerce

The importance of investment in cloud computing (CC) technology for conducting business has been widely acknowledged (e.g. Armbrust et al., 2010). As well as reducing cost, this Internet-based innovation can enhance the reliability, availability and flexibility of e-business (Tuncay, 2010). Like electricity, water, gas and telephony, which are accessed so frequently that they are always-on and paid for by consumer usage, CC is expected to become the fifth utility (Misra et al., 2011).

Among studies of CC adoption in technologically developing communities, Low et al. (2011) conducted a questionnaire-based survey of 111 high-tech firms in Taiwan. Their findings revealed that technological context (relative advantage, complexity and compatibility) and organizational context (top management support, firm size and technology readiness) significantly affect CC adoption. Investigating CC adoption in Saudi Arabia, Alhammadi et al. (2015) found that security concerns and government support were more influential than in technologically developed countries.

Few cost-benefit analyses have provided direct costings of CC implementation (Maheswaran, 2008; Schadler, 2009), and ROI has rarely been calculated (Misra et al., 2011). Some models suggest that cloud pricing makes it more suitable for small and medium rather than larger enterprises (Alhammadi et al., 2015). However, there is also evidence that CC capability contributes to e-commerce competitive advantage by enhancing methods of buying, selling and dealing with customers (Armbrust et al., 2010). Theoretically at least, cloud computing technology can address many e-commerce challenges through high service and infrastructure performance, cost savings and business security (Shah, 2014). To the best

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of the author's knowledge, however, no previous work has proposed or empirically tested a CC-based model for e-commerce adoption.

Research Model

The main aim of the current research was to explore the factors affecting CC-based e-commerce adoption and to suggest a model for a developing country. Emphasis was placed on user perceptions of organizational, technological and environmental factors, as these broadly encompass the e-commerce antecedents likely to be considered by business leaders (Molla et al., 2005a, 2005b; Tan et al., 2007, 2008) such as those sampled here. The literature review described earlier identified a number of relevant constructs; as the existing literature is characterized by an absence of rigorous research linking CC and e-commerce, the chosen constructs were those shown to be of relevance in both contexts. Given the exploratory stage of this research, thirteen constructs were selected to ensure wide coverage of potentially relevant variables, resulting in a relatively large number of initial hypotheses (twelve), subsequently refined through validity and reliability assessment as reported below.

From the existing literature, the following organization-related constructs were identified as relevant: firm size (FS) (Xu et al., 2004); organizational awareness (A) (Tan et al., 2007; Molla et al., 2005a; Blount et al., 2005); management commitment (C) (Molla et al., 2005a; Aljifri et al., 2003); available resources (R) (Zhuang et al., 2006); and management governance (G) (Tan et al., 2007; Molla et al., 2005a; Chatterjee et al., 2002). These constructs were hypothesized to affect e-commerce adoption in the present context as follows.

H1: Firm Size (FS) will have a positive impact on initial CC e-commerce adoption.
H2: Organizational awareness (A) will have a positive impact on initial CC e-commerce adoption.
H3: Management commitment (C) will have a positive impact on initial CC e-commerce adoption.
H4: Available resources (R) will have a positive impact on initial CC e-commerce adoption.
H5: Management governance (G) will have a positive impact on initial CC e-commerce adoption.

Again, building on previous research, the following cloud computing/technological constructs were identified as relevant: relative advantage (RA) (To et al., 2006); compatibility (CT) (Tan et al., 2008); complexity (CL) (Tan et al., 2008); and security concerns (SC) (Gangwar et al., 2015). These constructs were hypothesized to affect CC e-commerce adoption in the present context as follows.

H6: Relative advantage (RA) will have a positive impact on initial CC e-commerce adoption.
H7: Compatibility (CT) will have a positive impact on initial CC e-commerce adoption.
H8: Complexity (CL) will have a positive impact on initial CC e-commerce adoption.
H9: Security concerns (SC) will have a positive impact on initial CC e-commerce adoption.

On the same basis, the following environmental constructs were identified as relevant: government readiness (GVeR) (Kuan et al., 2001; Molla et al., 2005a); support industries' e-readiness (SIeR) (Au et al., 2001); and market forces e-readiness (SIeR) (Kshetri et al., 2002; Molla et al., 2005a). These constructs were hypothesized to affect CC e-commerce adoption in the present context as follows.

H10: Government readiness (GVeR) will have a positive impact on initial CC e-commerce adoption.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H11: Support industries' e-readiness (SIeR) will have a positive impact on initial CC e-commerce adoption.
H12: Market forces e-readiness (SIeR) will have a positive impact on initial CC e-commerce adoption.

For present purposes, CC-based e-commerce adoption is the key dependent variable, defined as interactive online selling and purchasing using CC technology (Tan et al., 2007; Molla et al., 2005a, 2005b; Zhu et al., 2003). CC-based e-commerce adoption is measured here on a scale rather than as a binary issue of whether companies adopted or not. Based on Molla et al.'s (2005a) scale, CC-based e-commerce adoption includes an interactive website for accepting orders and queries, as well as online selling and purchasing. Beyond the scope of this research, more advanced adoption may include company integration with suppliers, customers and back office systems for electronic completion of most business transactions.

The survey used here was based primarily on scales used in previous research on e-commerce and cloud computing adoption; independent variable items were assessed using a five-point Likert-type scale, ranging from strongly agree (1) to strongly disagree (5). The questionnaire was in English, which is the working language of a majority of companies in Egypt, especially in the IT sector. The following scales were adapted from Molla et al. (2005a): awareness (10 items), commitment (7 items), resources (16 items), governance (8 items), government e-readiness (5 items), support industries' e-readiness (4 items), market forces e-readiness (2 items) and CC-based e-commerce initial adoption (6 items). Scales for compatibility (3 items) and complexity (2 items) were adopted from Tan et al. (2008). Firm size (1 item) scale was adopted from Tan et al. (2007). The relative advantage scale (3 items) was adopted from To et al. (2006) and the security concerns scale (3 items) from Gangwar et al. (2015).

All research constructs, along with definitions, measurement item statements and previous use are listed in Table 7 in the Appendix. The survey form included a space at the end for an open-ended account of why a firm did or did not adopt CC-based e-commerce.

METHOD

Sampling and Procedure

The goal of the present study was to explain the role of organizational, technical and environmental factors in CC-based e-commerce adoption as perceived by top-level executives. Previous research in similar contexts suggested that this population would be sufficiently well-informed for present purposes (Molla et al., 2005a; Molla et al., 2005b; Tan et al., 2008; Tan et al., 2007). The data were collected in Egypt, which as a key player in African and Middle Eastern regions is widely seen as a model of information and communication (ICT) development (Boston Consulting Group, 2012). Although a regional leader in terms of web uptake, Egypt is also considered least prepared for e-commerce, and achieving widespread adoption is seen as a real challenge (El-Behary, 2015). Egypt's experience in this regard is informative for other developing countries.

The study sample was drawn from IT organizations in Egypt as listed in the official 2015 directory of the Egyptian Information Technology Industry Development Agency (ITIDA), a government entity spearheading the development of Egypt's ICT industry. Listing 1562 micro, small, medium and large companies, including 954 located exclusively in Cairo, the directory provided website and contact details for each company, including managing directors' email addresses. Managing directors of Cairo-based

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

companies were emailed the self-administered questionnaire, along with a covering letter introducing the researcher and the purpose of the study, explaining how to complete the questionnaire and the return deadline. Of 954 emails sent out in October 2015. 235 returned as undeliverable, either because of business closure or change of email address. To increase the response rate, a follow-up email was sent within two weeks. By the deadline, 187 responses were received, of which 12 were invalid because of missing data, yielding a total of 175 responses for a response rate approaching 26%. This sample size and response rate is considered adequate for technology adoption survey research (Molla et al., 2005b).

Data Analysis

Statistical analysis began with a descriptive analysis involving data screening. The validity and reliability of the research items and constructs were then assessed prior to model testing using multiple discriminant function analysis (MDFA). Calculation of CC ROI was based on responses to open-ended questions concerning CC costs and ROI.

Data Screening

Before data entry, questionnaires were coded and screened; each questionnaire was assigned a unique number, and each item was assigned a code to facilitate entry into SPSS. Each variable's frequency and range was assessed, and outliers (e.g. 22 or 44 entries) were corrected by revisiting the original questionnaire. Cases with missing values were evaluated for elimination; missing data may be ignored, representing 6% of sample size.

Item Reliability

Although all items were reported to be reliable in the literature, item reliability was checked by examining each item's loading and its correlation with the corresponding construct. According to Chin (1998), item loading and item-construct correlation should be at least 0.60. Based on the data in Table 1, items A1, A2, A5, A6, A9, R2, R5, R6, R8, R9, R10, R15 and R16 failed to meet this criterion, and these items were dropped. All remaining items were found to achieve adequate reliability.

Construct Reliability

Construct reliability was assessed by examining construct composite reliability, Average Variance Extracted (AVE) and Cronbach's alpha. According to Fornell and Larker (1981), a composite reliability value of .80 or greater indicates strong composite reliability; AVE should be greater than 0.50 to demonstrate significant variance, with a Cronbach's alpha of at least 0.6 (Keil et al., 2000). As shown in Table 2, the constructs commitment and governance achieved composite reliability, AVE and Cronbach's Alpha less than 0.5. Accordingly, these two constructs were dropped from the research model. In contrast, all remaining constructs returned composite reliability scores above 0.8, with AVE scores exceeding 0.5 and Cronbach's alpha higher than 0.6. On that basis, these remaining constructs showed adequate reliability.

Item Correlations

Each item was found to correlate more highly with other questions measuring the same construct than with other items measuring other constructs, confirming discriminant validity (Keil et al., 2000). A confirmatory factor analysis calculating T-values for item loadings verified that each item's loading was much higher on its assigned construct than on other constructs (Gefen, 2000), confirming their discriminant validity.

Construct Validity

Although all research constructs were measured using established scales, it was still necessary to validate the measures, using the correlation coefficient between each construct and its associated items as measured by Pearson's correlation coefficient. A significant correlation was found between all constructs and their associated items. Correlations between variables are presented in Table 3; these were significant for most model constructs.

Table 3. Correlation Coefficient between Constructs

Constructs		A	R	RA	CT	CL	SC	GVeR	SIeR	MFeR

Final Reliability

As illustrated in Table 4, a reliability check was done for the final instrument, which included 9 constructs and 35 items, including 5 assessing *awareness*, 8 assessing *resources* and 5 assessing *government e-readiness*. Relative advantage, compatibility, complexity, security concerns and support industries' e-readiness were each assessed by three items, and market forces e-readiness by two items. To be considered reliable, a measure's Cronbach alpha should not be less than 0.80; all the reliability coefficients satisfied this minimum criterion, indicating that the instrument was sufficiently reliable.

Table 4. Instrument Reliability

Construct	Number of Items	Cronbach Alpha
Awareness (A)	5	0.821
Resources (R)	8	0.869
Relative Advantage (RA)	3	0.801
Compatibility (CT)	3	0.897
Complexity (CL)	3	0.802
Security Concerns (SC)	3	0.912
Government e-readiness (GVeR)	5	0.867
Supportive Industries e-Readiness (SIeR)	3	0.923
Market Forces e-Readiness (MFeR)	2	0.834

RESULTS

Sample

In total, 175 top-level executives completed and returned the survey. A majority of these companies (64%) had been in business for more than 5 years, and 55% had 50–500 employees. A majority of respondents (59%) were managing directors or general managers; others included technical IT directors (24%), marketing directors (10%) and accounting directors (7%).

Cloud-Based E-Commerce Adoption

Of the 175 respondents, 50 (28%) indicated that their company was connected to the Internet with email and a static website, publishing company information without interactivity. A further 104 respondents (60%) indicated that their company was connected to the Internet with an interactive website accepting queries and entry from users. Finally, 21 respondents (12%) indicated that their company conducting online selling of products and services using the cloud.

Participating firms were categorized by number of employees as follows: small (50 employees or fewer); medium (50–500); and large (more than 500). The results suggest that small and medium size firms were more willing to adopt e-commerce. As all 21 firms reporting initial adoption of cloud-based e-commerce were either small or medium sized, hypothesis H1 was supported (Table 5).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. CC-based e-commerce adoption (self-report)

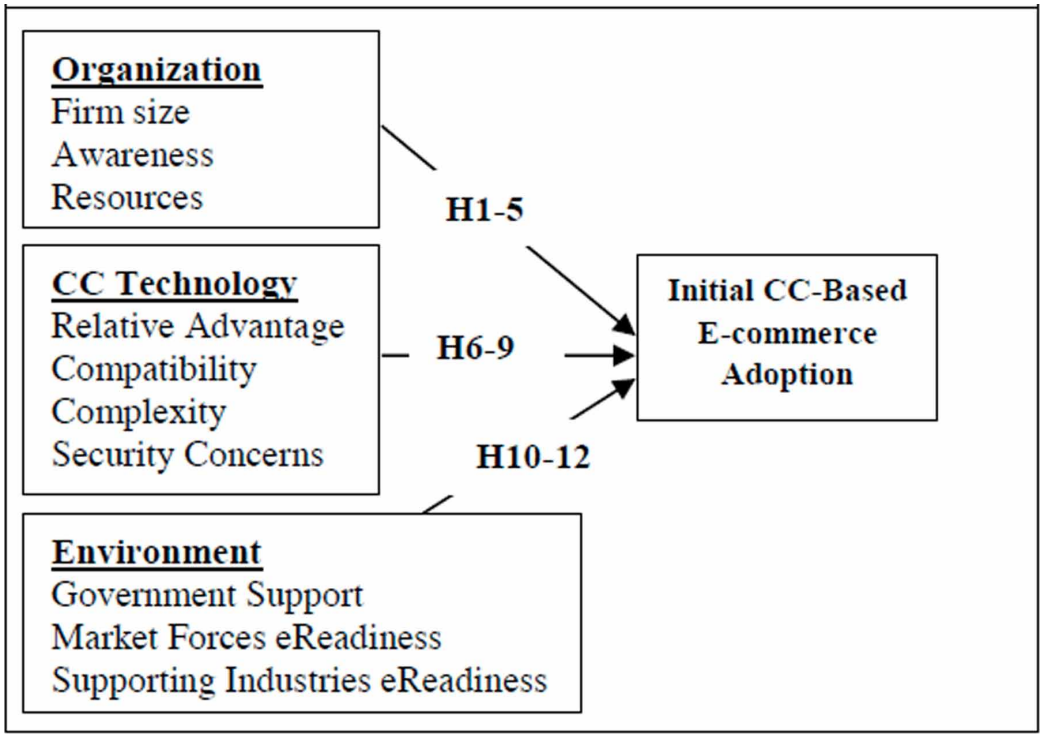
Adoption Level	Frequency	Percentage
Not connected to the Internet with no emails	0	0
Connected to the Internet with emails but no web site	0	0
Static web site publishing basic company information without interactivity	50	28
Interactive web site accepting queries and entry from users	104	60
Interactive CC-based e-commerce online selling and purchasing	21	12

Model Testing

The proposed model of CC-based e-commerce adoption in **Figure 1** was tested using multiple discriminant function analysis (MDFA). This technique is appropriate in cases involving interval independent variables and categorical dependent variables (Hair et al., 1995). Here, all independent variables were measured on a five-point Likert scale while dependent variables were operationalized as categories, selecting among five levels of initial adoption.

Following Hair et al.'s (1995) guidelines, MDFA included derivation, validation and interpretation. The derivation stage determined whether a statistically significant discriminant function distinguished between adopters and non-adopters. The validation stage checked predictive accuracy using the hit ratio and the Mahalanobis distance. In the interpretation stage, independent variables with factor loadings greater than or equal to 0.30 were identified as significant contributors to the model (Hair et al., 1995).

Figure 1. Cloud computing-based e-commerce suggested model



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

For present purposes, initial adopters were identified as companies using interactive e-commerce for exchange of product and services online through CC technology (Molla et al., 2005a). Non-adopters were those with either a static website or a dynamic one accepting only queries with no transactions, or those without a web presence. Based on Hair et al.'s (1995) significance levels, MDFA for the initial adoption model showed a statistically significant function (Wilks's $\lambda = 0.23$; $\chi 2 = 187.54$; df = 8; $F = 42.55$, $p < 0.0001$), indicating that the model satisfactorily discriminates between initial adopters and non-adopters, correctly classifying 78% of the businesses in the sample by hit ratio. Hair et al. (1995) defined the acceptable hit rate as 52.6%; additionally, the Mahalanobis distance ($D2$) is 9, which suffices to support validity. Accordingly, the model can be said to be a valid predictor of CC-based e-commerce adopters and non-adopters.

Based on the discriminant loadings and probabilities for *f* statistics in Table 6, the following constructs can be said to significantly affect initial CC-based e-commerce adoption: *awareness*, *resources*, *compatibility*, *government e-readiness*, support industries' e-readiness and *market forces e-readiness*. As these factors seem likely to significantly affect initial adoption of CC-based e-commerce, hypotheses H2, H4, H7, H10, H11, and H12 were supported.

Table 6. Discriminant Analysis of the Initial Adoption of CC-based e-commerce

Construct	Discriminant Loading	*F*-Value	*P*-Level	Coefficient	Non-Adopters (N= 154)		Adopters (N= 21)	
					Mean	SD	Mean	SD
H2: Awareness (A)→ EA: Supported	0.632	61	0.000	0.671	2.57	0.71	3.45	1.04

Return on Investment

While cost was not among the constructs considered here, responses to the survey's open-ended questions highlighted the importance of cloud cost for the adoption decision. For that reason, the researcher contacted a number of the participating firms to follow up on CC cost and ROI issues.

Cloud costs are calculated on a monthly or yearly basis of pay-per-use. For startups who used cloud technology rather than investing in data centres, cloud return on investment could be calculated simply as ((annual profit - cloud cost)/cloud cost). For firms shifting from data centres to cloud, cost saving

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

would be the elimination of all datacenter costs (following complete migration) or a reduction in datacenter costs (following partial migration). Increased profits related to CC can be calculated as annual profit increase plus decrease in disaster recovery cost (Misra et al., 2011). On that basis, the following equations enable calculation of cloud ROI.

$$ROI_{\text{per year}} = (\text{profit increase}_{\text{per year}} + \text{cost reduction}_{\text{per year}} - \text{cloud cost}_{\text{per year}}) \div (\text{cloud cost}_{\text{per year}}),$$

where $\text{profit increase}_{\text{per year}} = (\text{annual profit}_{\text{after cloud adoption}} - \text{annual profit}_{\text{before cloud adoption}}) + (\text{disaster recovery cost}_{\text{before cloud adoption}} - \text{disaster recovery cost}_{\text{after cloud adoption}})$.

$\text{Cost reduction}_{\text{per year}} = (\#\text{ of servers}_{\text{before cloud adoption}} - \#\text{ of servers}_{\text{after cloud adoption}}) \times \text{server cost}_{\text{per year}}$.
$\text{Server cost}_{\text{per year}} = \text{yearly cost of (electricity + manpower + maintenance + software + backup)}$.
$\text{Cloud cost}_{\text{per year}} = \text{yearly cost of (storage in cloud + bandwidth + application use)}$.
$\text{Storage cost}_{\text{per year}} = \#\text{ of GB stored in cloud} \times \text{cost per GB}_{\text{per year}}$.
$\text{Bandwidth cost}_{\text{per year}} = (\#\text{ of incoming GB} + \#\text{ of outgoing GB})_{\text{per year}} \times \text{cost per GB}_{\text{per year}}$.
$\text{Application cost}_{\text{per year}} = \#\text{ of application used} \times \text{time of application use}_{\text{per hour}} \times \text{cost}_{\text{per hour per application}}$.

While no detailed costs were disclosed, one startup and one large firm (with more than 500 employees) provided holistic ROI data. The start-up firm had worked for three years in e-booking for hotels and vans with a cloud-based infrastructure and reported an approximate annual ROI of 20%. The large firm had worked for ten years on B2B with global partners and reported a 0.5% ROI following recent partial migration from data centres to cloud technology. In this firm, the decision to migrate to cloud was based on faster time to market, fulfilment of partners' needs and additional revenue, even if running costs were higher.

DISCUSSION

This study establishes a novel framework for integrating e-commerce and cloud computing in a single model, which was empirically tested and highlights factors that may affect CC e-commerce adoption in developing countries. The model was found valid in discriminating between adopters and non-adopters as well as the degree of initial adoption in the present context. These findings indicate that adoption of innovations like cloud computing and e-commerce, which are relatively new to some developing countries, depends to a considerable extent on organizational, technological and environmental factors.

Among organizational determinants, firm size, awareness and resources were found to affect CC-based e-commerce adoption. While small and medium-sized firms might lack technological and financial resources, their less complex structure makes them more adaptable to change and more willing to adopt new technologies.

The findings lend empirical support to the previously reported positive effect of organizational awareness on adoption of e-commerce (Tan et al., 2007; Molla et al., 2005a; Blount et al., 2005) and cloud computing (Low et al., 2011), indicating that the organizations in developing countries most likely to move to cloud computing e-commerce are those most conscious of and responsive to the application of IT innovations in terms of opportunities, potential benefits and possible threats, and with a good understanding of relevant business models and application solutions.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

In the present context, technological, business and manpower resources can be seen to significantly affect CC e-commerce adoption. Organizations with appropriate human expertise, flexible systems, and cloud-friendly technical infrastructure are keener to adopt CC-based e-commerce. According to respondents, data centres are much less expensive in Egypt than the large bandwidth required for cloud. Organizations that have already invested in large, stable data centres are unlikely to forego these for more costly and risky options. Additionally, as technical manpower is available and cheap in Egypt, large organizations with sufficient technical staff are unlikely to adopt CC to reduce human resource costs. For these reasons, the competitive advance of CC as an inexpensive and utility technology may prove more significant in other countries where bandwidth is cheaper and technical manpower is more expensive.

Among technological determinants, only CC compatibility was found to influence initial adoption. This suggests migration is more likely if CC is perceived to align with an organization's existing systems and needs. The remaining technological variables (relative advantage, complexity and security concerns) appear to have no significant effect on adoption of CC e-commerce in the present context, which is inconsistent with previous studies (Tan et al., 2008; To et al., 2006; Low et al., 2011; Alhammadi et al., 2015; Gangwar et al., 2015). One possible explanation is that these factors are necessary but insufficient; validation of this finding would require further investigation of the model in another developing country. Another possible reason, as discussed previously, is that cloud computing is a relatively new and expensive technology, at least in Egypt.

Supporting industries, government and market forces are three factors that appear to affect initial adoption of e-commerce. The findings indicate that government support can motivate CC-based e-commerce applications through effective legislation, as well as legal, customs and tax environments. Support industries' e-readiness, in terms of the availability of secured telecommunication infrastructures, was also found to be essential for e-commerce diffusion. In some developing countries, telecommunications infrastructure is provided solely by government entities, lending further importance to government support in terms of legal frameworks as well as telecommunications and security infrastructure. More specifically, in a cloud computing context, government regulation and initiatives in technologically developing countries play a major role in encouraging enterprises to adopt new technologies (Alhammadi et al., 2015). According to our respondents, as the few cloud services providers in Egypt commonly provide only hosting services, their reliability is not yet well established. Instead, most businesses employ cloud providers in the US or Europe, adding further to operational costs. However, market forces were found to have a significant effect on adoption, supporting previous evidence of this factor's role in facilitating e-commerce diffusion (Molla et al., 2005a; Kshetri et al., 2002). It seems clear that, in developing countries, businesses with global customers and business partners and/or multinational supply chains are most likely to spearhead the latest technology to avoid market displacement.

CONCLUSION

This study advanced and empirically tested a novel framework, integrating adoption of e-commerce and cloud computing in a single model. The organizational, technical and environmental antecedents of cloud computing-based e-commerce adoption were explored in Egypt as an example of a developing country. The findings identified organizational resources related to technology, business and manpower, and the compatibility of these resources with cloud computing technologies, as significant influences on cloud computing-based ecommerce adoption. Organizational awareness of opportunities, potential

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

benefits and possible threats were also found to affect the adoption decision. Small and medium-sized firms were found to be more ready to adopt cloud computing-based e-commerce, as ROI was found to be higher in small or start-up firms when compared to larger companies.

Supporting industries, governments and market forces readiness were identified as three contextual factors that affect initial adoption of cloud-based e-commerce. In many developing countries, government support is even more important, comprising legal support as well as provision of telecommunications and security infrastructure, along with appropriate tax and customs regulations. The current lack of local and regional cloud providers means that many businesses in Egypt employ cloud providers in US or Europe, adding further operational costs. The findings also indicate that in some developing countries with high-cost telecommunications and low-cost manpower, cloud computing may not be the best option for some firms. Those with links to global customers and business partners and/or multinational supply chains are most likely to deploy cloud e-commerce technology to ensure faster time to market.

In summary, cloud-based e-commerce can play a major role in boosting developing countries' economies, with adoption of such technologies built on government support, cloud providers and multinational partners. Awareness within the organization and compatibility of existing resources with cloud play a major role in adoption, with a higher return on investment for small to medium firms. Government, non-government organizations and business leaders can draw on the implications of this study to identify internal and external opportunities for CC e-commerce initiatives in technologically developing communities.

Methodological Implications

A key methodological strength of this research was the integration of antecedents of e-commerce and cloud computing adoption in a single model, along with validation of this model as a relevant framework for studying cloud-based e-commerce in developing countries. The proposed model encompasses most aspects of innovation adoption under three major research constructs: organizational, technical and environmental factors. This research contributes methodologically to the study of CC e-commerce adoption. First, contrary to assumptions in most of the existing literature, cloud adoption in developing countries is affected more by readiness and support within and outside organizations than by technical issues. These findings challenge the previous focus on technical aspects of cloud computing (such as relative advantage, security issues and technical complexity) as the main constraints on adoption, aligning instead with previous findings concerning the importance of internal organizational capabilities and the compatibility of organization's resources with the innovation technology for adoption in developing countries. The present findings suggest that firms with human, technological and business resources that are perceived as compatible with cloud computing technology are more open to cloud e-commerce adoption, not least because they also have an adequate awareness of potential benefits and threats. Second, the study highlights the major role of government as the main and sometimes sole provider of infrastructure and services in most developing countries. Finally, the study highlights the influence of international markets on developing markets, where new technologies in global markets serve as a catalyst for developing market innovation.

Practical Implications

Business leaders can apply the current findings to assess business, technical and human resources within their organization and to evaluate the compatibility of these resources with cloud-based e-commerce

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

adoption. Potential risks were identified in terms of government readiness related to legal infrastructure, as well as service providers' readiness concerning available, reliable and affordable secured technical infrastructure. The equations for return on investment in cloud computing provided here may encourage business leaders and new startup entrepreneurs to calculate cost savings and profit increase in migrating to cloud. This research may also encourage developing organizations to monitor new innovations in international markets and to become more aware of how these changes impact on their revenue. Organizations with international partners are keener to adopt such innovations in pursuit of faster time to global market.

Service providers, government entities and international organizations seeking to expand in developing markets could use the proposed model to understand the factors affecting cloud e-commerce adoption in developing countries. In most developing countries, although Internet infrastructure is reliable enough, and there is affordable and skilled technical manpower, e-business remains underdeveloped. The present findings suggest that this owes in part to a lack of credibility of local service providers, as well as the high cost of communication lines. It follows that investment in appropriate legal regulation and lower-cost bandwidth is a pressing issue for governments and private service providers. As essential steps, governments of developing countries must encourage high technology service providers while also legislating to control online payments and charging mechanisms for cloud services.

Limitations and Future Work

The present study is among the first to link cloud computing technology with an e-commerce adoption model in the context of a developing country. Further testing and refinement of the proposed model is needed to resolve issues related to the items and constructs dropped from the model. As the study investigated only IT companies working in Egypt, future research using a larger sample drawn from various industries and applied in other developing countries can test the relevance of the model and whether these results are replicable.

Additionally, the quantitative approach adopted here could not fully capture the reasons underlying participants' perceptions of key constructs. Their qualitative responses at the end of the survey highlighted additional themes not included in the model, such as the high cost of communication lines and the small number of cloud providers in Egypt. These findings suggest additional constructs that could usefully be explored further.

APPENDIX

Table 7. Survey items

Constructs & References	Items	Measures
Firm Size (FS) Tan et al., 2007	FS1	how many employees are there in your company? (> 50, 50-500, more than 500)
Awareness (A) Molla et al., 2005a	A1	CC-based e-commerce is not yet applicable to our environment
	A2	CC-based e-commerce applications are becoming common with our partners
	A3	Businesses with whom our organization is competing are implementing CC-based e-commerce
	A4	Our business recognizes the opportunities and threats enabled by CC-based e-commerce
	A5	We has a good understanding of CC-based e-commerce business models applicable to our business
	A6	We have a good understanding of CC-based e-commerce application solutions for our business
	A7	We have a clear understanding of the potential benefits of CC-based e-commerce to our business
	A8	Our organization believes that the gain from CC-based e-commerce outweighs its cost
	A9	We consider that CC-based e-commerce has a tremendous impact on our business
	A10	In general our business has adequate awareness about CC-based e-commerce
Commitment (C) Molla et al., 2005a	C1	We have a clear vision on CC-based e-commerce
	C2	Vision of CC-based e-commerce activities is understood in our company
	C3	Our CC-based e-commerce implementations are strategy-led
	C4	Senior management lead our CC-based e-commerce initiatives
	C5	We have staffed our CC-based e-commerce projects with the proper resources to achieve their goals
	C6	We have CC-based e-commerce mind-set at all levels of management
	C7	Our business demonstrates adequate level of commitment in CC-based e-commerce
Human Resources (HR) Tan et al., 2007	R1	Most of our employees are computer literate
	R2	Most of our employees have unrestricted access to computers
	R3	Most of our employees have unrestricted Internet access
Business Resources (BR) Molla et al., 2005a	R4	We have necessary technical and managerial skills to implement CC-based e-commerce
	R5	Our organization has a culture of enterprise wide information sharing
	R6	We have a policy that encourages CC-based e-commerce initiatives
	R7	We are aggressive in experimenting with new technologies
	R8	Failure can be tolerated in our organization
	R9	Our organization is capable of dealing with rapid changes
	R10	We have strong relationships with our suppliers and customers
	R11	We have sufficient experience with network based applications
	R12	We sufficiently invest in our CC-based e-commerce projects
	R13	We have business resources to implement CC-based e-commerce
	R14	Our existing systems allow us to make changes for CC-based e-commerce applications
	R15	We have an established enterprise-wide IT infrastructure
	R16	Our existing systems are flexible

Table 7. Continued

Constructs & References	Items	Measures
Governance (G) Molla et al., 2005a	G1	Roles and responsibilities are clear for CC-based e-commerce initiative
	G2	CC-based e-commerce accountability is extracted via on-going responsibility
	G3	Decision-making authority has been clearly assigned for all CC-based e-commerce initiatives
	G4	Our managers demonstrate readiness for change
	G5	We thoroughly analyze the possible changes to be caused in our organization, suppliers, partners, and customers as a result of each CC-based e-commerce implementation
	G6	We follow a systematic process for managing change issues as a result of CC-based e-commerce
	G7	We have clearly defined metrics for assessing the impact of our CC-based e-commerce initiatives
	G8	We have an effective governance model in our CC-based e-commerce
Relative Advantage (RA) To et al., 2006	RA1	Using CC-based e-commerce technology would increase our business opportunities
	RA2	Using CC-based e-commerce would improve our customer services
	RA3	Using CC-based e-commerce would enhance our competitiveness
Compatibility (CT) Tan et al., 2008	CT1	CC-based e-commerce technology is fitting with the existing resources
	CT2	CC-based e-commerce technology is matching our needs
	CT3	CC-based e-commerce technology suited the staff previous experiences
Complexity (CL) Tan et al., 2008	CL1	CC-based e-commerce technology is difficult to understand
	CL2	CC-based e-commerce technology is difficult to use
Security Concerns (SC) Gangwar et al., 2015	SC1	We believe that CC technology ensure security controls for our data
	SC2	We believe that CC technology prevent unauthorized access for our data
	SC3	We consider CC technology as a safe environment for business

Chapter 17
The Moderating Effects of Gender on E-Commerce Systems Adoption Factors

Frederick Pobee
University of Pécs, Hungary

Daniel Opoku
School of Business, Department of Human Resource, University of Education, Winneba, Ghana

ABSTRACT

The purpose of this article was to investigate the moderating effects of gender on e-commerce systems adoption factors among university lecturers in Ghana. In order to achieve this purpose, the unified theory of acceptance and use of technology (UTAUT) was used as the theoretical lens for the study. Eight hypotheses were developed and tested. Data analysis was performed with a structural equation modeling (SEM) technique using SmartPLS Application. Using a survey of 223 respondents, the study showed that factors such as performance expectancy, effort expectancy, and facilitating conditions positively and significantly influenced Ghanaian lecturers' behavioral intention and ultimately the actual use of e-commerce systems. As for the moderating effects of gender, this study discovered that gender insignificantly moderated the effects of performance expectancy, effort expectancy and social influence on behavioral intention.

1. INTRODUCTION

In recent times, e-commerce has revolutionized the conduct of business to a large extent. Electronic commerce (EC) has substantial potential to foster the growth of businesses being it small or medium-sized enterprises (SMEs) in developed and developing countries (Wang et al., 2016; Chen, 2012; Kauffman et al., 2010; Choshin & Ghaffari, 2017; Yang et al., 2015). It comes as no surprise that the e-commerce systems adoption research has seen much attention in recent times (Ueasangkomsate, 2015; Thorleuchter & Van den Poel, 2012; Kim & Peterson, 2017; Oliveira et al., 2017; Wang et al., 2016; Hallikainen &

Laukkanen, 2018; Kaur & Khanam Quareshi, 2015; Hwang & Lee, 2012; Capece et al., 2012; Rahayu & Day, 2016). For a successful e-commerce systems implementation, e-commerce researchers and practitioners must have an in-depth of online customer behavior. Even though there are research endeavors to explain e-commerce system adoption and online consumer behavior (Chiliya et al., 2011; Govindaraju et al., 2015; Kartiwi & MacGregor, 2008; Triandini et al., 2017), one of the main questions is how to understand the influences of social normative and affective factors on electronic customer relationship management. Lian & Yen (2014) also recently called for research to investigate the moderating effects of gender in e-commerce systems adoption. Arguably, among the many characteristics that impact the use of e-commerce, one that has received relatively little attention is gender. Extant evidence suggests that men and women differ in their beliefs regarding the use of information technology-related innovations, including ecommerce (Zhou & Wang, 2010; Wang, Wu & Wang 2009; Van Slyke et al., 2010). However, less is known about how gender moderates the impact of various beliefs on behavioral intentions.

Despite this great attention by the researchers, studies on the moderating effects of gender on e-commerce systems adoption is still far behind (Hasan, 2010; Saeed et al., 2003a, 2003b; Lian & Yen, 2014). This raises the question as to what are the precise factors that influence gender in their adoption of e-commerce. The answer is important as it is widely known that the e-commerce can revolutionize the conduct of business globally and play an important role in economic development. E-commerce make a significant contribution not only in terms of its technological and managerial benefits but also in terms of development and opportunities it provides (Yeh et al., 2014). This study fills this knowledge gap by investigating the factors responsible for gender differences in the adoption factors of e-commerce adoption.

It cannot be denied that there have been studies conducted regarding e-commerce adoption by organizations/businesses, however most of these focus on developed countries (Williams, Dwivedi, Lal, & Schwarz, 2009; Daniel & Grimshaw, 2002). Studies that focus on e-commerce in developing countries are rarely found. As commonly known, there is a difference between developing countries and developed countries. These differences are not only from an economic standpoint, but they also concern political, environmental and social as well as cultural factors. Therefore, research findings obtained from developed countries cannot be applied directly to developing countries.

The potential tendency for e-commerce to foster the growth of businesses in developing countries calls for further research to better enhance the understanding of e-commerce adoption in the context of developing economies. Motivated from these gaps, this study aims to investigate the moderating effects of gender on e-commerce adoption factors in Ghana.

The organization of this paper is as follows: Section 2 presents the theoretical foundations and literature; Section 3 presents the research model and hypotheses; Section 4 outlines the research methodology and analysis; Section 5 presents the discussion of the findings, and Section 6 presents limitations of the study and suggestions for future research. Section 7 concludes the study.

2. THEORETICAL FOUNDATION AND LITERATURE

2.1. The Unified Theory of Acceptance and Use of Technology (UTAUT)

The unified theory of acceptance and use of technology (UTAUT) is over a decade old and has been used extensively in information systems (IS) and other fields. UTAUT was originally devised in order to explain the factors that affect the acceptance and use of ICT by employees. Nevertheless, in numerous

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

studies it has been applied in a consumer context. Furthermore, UTAUT has become a popular theoretical choice within the field of ICT (Williams, Rana, Dwivedi, & Lal, 2011). Examples of applications of the UTAUT in consumer contexts include the adoption by users of the following information and communication technologies: mobile banking (Zhou, Lu, & Wang, 2010); mobile phone technologies (Lu, Yao, & Yu, 2005; Park, Yang, & Lehto, 2007; Wang & Wang, 2010; Zhou, 2011); online family dispute resolution services (Casey & Wilson-Evered, 2012); location-based services (Xu & Gupta, 2009); question answer services (Deng, Liu, & Qi, 2011); Internet banking (Abushanab & Pearson, 2007; Im, Hong, & Kang, 2011; Riffai, Grantb, & Edgarc, 2012); virtual learning technologies (Chiu & Wang, 2008); e-government (Hung, Wang, & Chou, 2007; Sapio et al., 2010; Schaupp, Carter, & McBride, 2010; Wang & Shih, 2009); e-recruiting (Laumer, Eckhardt, & Trunk, 2010); and online purchase intention in regard to rural tourism (San Martín & Herrero, 2012). Additionally, in the area of organizations the UTAUT model has been applied to technologies such as: computer use (Al-Gahtani, Hubona, & Wang, 2007); electronic commerce applications (Sutanonpaiboon & Pearson, 2006; Wymer & Regan, 2005); virtual learning technologies (Van Raaij & Schepers, 2008; Wang, Wu, & Wang, 2009); human resources databases (Eckhardt, Laumer, & Weitzel, 2009); organizational social networks (Curtis et al., 2010; Sykes, Venkatesh, & Gosain, 2009); e-government (Gupta, Dasgupta, & Gupta, 2008); and health information systems (Alapetite, Andersen, & Hertzum, 2009; Chang, Hwang, Hung, & Li, 2007; Duyck et al., 2010; Kijsanayotin, Pannarunothai, & Speedie, 2009).

The UTAUT states that behaviour/actual use of a system is preceded by intention with intention being influenced by performance expectancy (PE), effort expectancy (EE), social influence (SI) and facilitating conditions (FC). PE refers to the degree to which an individual believes that using a system will be beneficial or improve his/her job performance (Venkatesh et al., 2003). EE refers to the degree of ease associated with the use of a system (Venkatesh et al., 2003). SI refers to external actors that can influence an individual perception on system use. Examples of these factors are family, friends and mass media (Venkatesh et al., 2003). FC refers to the degree to which an individual believes that an organizational and technical infrastructure exists to support use of the system (Venkatesh et al., 2003). The definitions and root constructs of the four constructs of UTAUT is provided in Table 1.

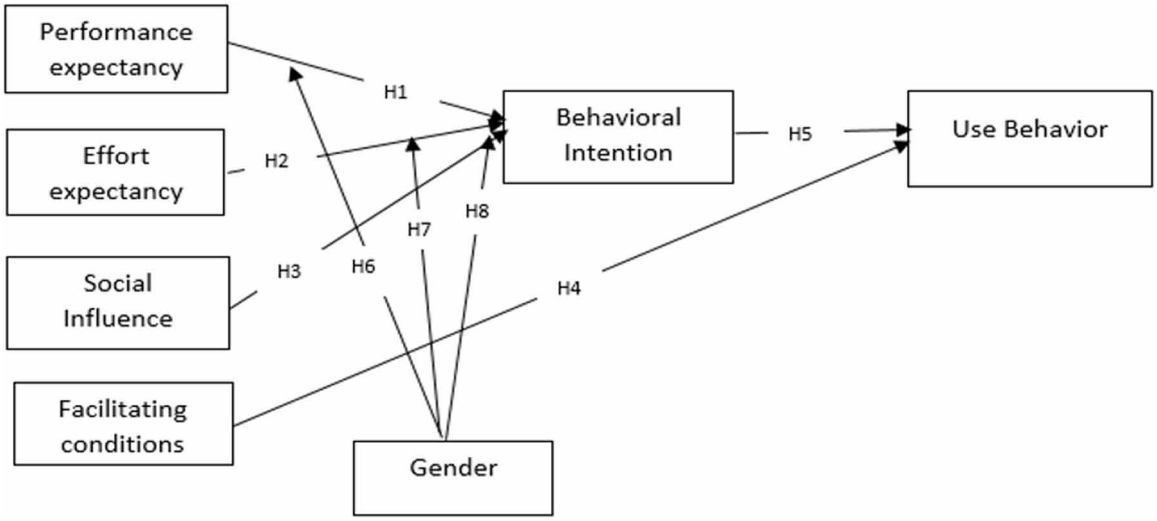
Table 1. Definitions and root constructs for the four constructs (Venkatesh et al. 2003)

Construct	Definition	Root constructs
Performance expectancy	The degree to which an individual believes that using the system will help him or her to attain gains in performance	Perceived Usefulness from Technology Acceptance Model (TAM)
Effort expectancy	The degree of ease associated with the use of the system	Perceived ease of use' from TAM
Social influence	The degree to which an individual perceived that important others believe he or she should use the new system	Subjective norm in Theory of Reasoned Action (TRA), TAM2, Theory of Planned Behaviour (TPB)
Facilitating conditions	The degree to which an individual believes that an organizational and technical infrastructure exists to support use of the system.	Perceived behavioral control' from TPB

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. RESEARCH MODEL AND HYPOTHESES

Figure 1. Theoretical framework. Source: UTAUT model (Venkatesh et al. 2003)



A number of e-commerce studies have been conducted based on the UTAUT model (Figure 1). Gupta et al. (2008) found that performance expectation, effort expectation, social influence, and facilitating conditions affect users' behavioral intentions toward ICT in an e-government context. Similar findings were also found in a study conducted by Schaupp et al. (2010). Chiu and Wang (2008) added the ''subjective task value'' construct in their study of user intentions regarding the continuing use of online learning. They found that the performance expectation and effort expectation are significant variables. Similar studies conducted by Pynoo et al. (2011) which focused on teacher acceptance of digital learning, and Qingfei et al. (2008) which focused on user acceptance of mobile commerce confirmed the importance of the four drivers in the context of EC. Zhou et al. (2010) integrated the Task Technology Fit (TTF) and UTAUT models to understand users' behavioral intentions toward mobile banking and found that, with the exception of effort expectation, the other three drivers have significant effects. Based on the above discussion, the four drivers belonging to UTAUT have sufficient explanatory power in an EC environment context.

According to a study by Agarwal & Prasad (1998), performance expectancy is the strongest predictor of intention behavioral action. The predictive effect of performance expectancy is mediated by age, gender and experience. Previous research by Calvert et al. (2005) found that at early ages there was no significant difference between males and females in using computers however, at later ages, females' interest wanes. In related research by Afarikumah & Acheampong (2010), the perception of computer usefulness was found to be irrespective of gender and age of tertiary students. In view of the above discussion, the researchers hypothesized that:

H1. Performance expectancy will positively affect lecturers' intention to adopt e-commerce systems.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The effort expectancy construct within each model is significant in both voluntary and mandatory usage contexts; however, each one is significant during the first time period, becoming non-significant over periods of extended and sustained usage (Venkatesh et al., 2003) which is consistent with previous research (e.g., Agarwal & Prasad, 1997, 1998; Davis et al., 1989; Thompson et al., 1991, 1994). To this end we expect effort expectancy to be more prominent in the embryonic stage of every behavioral intention for Ghanaian lecturers to adopt e-commerce system. It is also expected that increased levels of ease of use of e-commerce systems will also increase the behavioral intention to use the system. As a result, the researchers hypothesized:

H2. Effort expectancy will positively affect lecturers' intention to adopt e-commerce systems.

Social influence in all the models contains the explicit or implicit notion that the individual's behaviour is influenced by the way in which they believe others will view them as a result of having used the technology (Venkatesh et al., 2003). Social influence can directly affect intention to use technology. Family, friends and even media can influence the overall behavioral intention to adopt e-commerce systems. According to Hartwick and Barki, (1994) reliance on others' opinions in technology acceptance literature is significant only in mandatory settings. Thus, the authors hypothesized that:

H3. Social Influence will positively affect lecturers' intention to adopt e-commerce systems.

According to the authors of the UTAUT model, facilitating conditions have a positive relationship with technology usage. In earlier models such as Theory of Planned Behavior and DTPB, facilitating conditions predict intention when effort expectancy is unavailable. However, in MPCU and IDT, prediction of facilitating conditions on behavioral intention is non-significant (Venkatesh et al 2003). In situations where an individual believes that support to use technology is erratic, influence on intentions to use technology will be significant. However, where the support is consistent we expect facilitating conditions to directly influence use behavior. It is therefore expected that facilitating conditions will predict use behavior.

H4. Facilitating conditions will positively affect lecturers' use behavior to adopt e-commerce systems.
H5. Behavioral intention will positively affect lecturers' User behavior to adopt e-commerce systems.

3.1. Gender Effect

The ''gender gap'' in IT acceptance has been well documented in prior studies (Bae & Lee, 2011; Fan & Miao, 2012; Garbarino & Strahilevitz, 2004; Nirmala & Dewi, 2011; Sangran et al., 2009; Sebastianelli et al., 2008; Seock & Bailey, 2008; Stafford et al., 2004; Van Slyke, Belanger, Johnson, & Hightower, 2010; Van Slyke et al., 2002; Wu, 2003). Following are related findings. Van Slyke et al. (2002) noted that, in general, men are more likely to try a new IT than are women. In other words, in comparison with females, males tend to have higher Personal Innovativeness of IT (PIIT) and online shopping is no exception (Bae & Lee, 2011; Sangran et al., 2009; Seock & Bailey, 2008; Van Slyke et al., 2010). Sangran et al. (2009) indicated that men and women have different motivations for shopping online. Van Slyke et al. (2002) found that men like to shop online more than woman do. Additionally, men have significantly more positive perceptions regarding compatibility, complexity, relative advantage, result

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

demonstrability, and trust than woman do. Similar findings were also noted by Garbarino and Strahilevitz (2004) who indicated that woman have higher levels of perceived risk regarding online shopping than men have. Therefore, a friend's recommendation has a greater effect onto a woman's intention to shop online than it has for a man's. In other words, because women perceive the risk of shopping online as high, recommendations from friends will reduce that perceived risk and increase their intention to shop online. Bae and Lee (2011) reported similar findings. Fan and Miao (2012) studied the effects of electronic word-of- mouth and found that males and females have different online shopping behaviors. Wu (2003) also found that, in comparison with women, men have a relatively more positive attitude toward online shopping. Additionally, men and women have different preferences regarding different online shopping product types (Nirmala & Dewi, 2011; Sebastianelli et al., 2008). Stafford et al. (2004) noted that this gender gap in the context of online shopping also exists across different cultures and nationalities. This is why it will be necessary to study this gender gap within the Ghanaian context.

Consequently, the following hypotheses are proposed to understand the moderating effect of gender on the EC systems adoption among Ghanaian lecturers.

H6. The influence on performance expectancy on Ghanaian lecturers' intention to adopt e-commerce systems will be moderated by gender.

H7. The influence on effort expectancy on Ghanaian lecturers' intention to adopt e-commerce systems will be moderated by gender.

H8. The influence on social influence on Ghanaian lecturers' intention to adopt e-commerce systems will be moderated by gender.

4. RESEARCH METHODOLOGY AND ANALYSIS

The purpose of this study is to gain clear understanding of the factors that influence user's intention to adopt e-commerce system. This study adopted the survey as the research design. This was to enable the test of the hypotheses and provide a basis to generalize the findings. The sample consisted of lecturers in Ghana who use e-commerce platform. Questionnaires were sent to two hundred and forty-five lecturers who use E-commerce platform such as Jumia Ghana, eShopAfrica, Heel the World, Lamudi, Tisu and zoobashop. Out of the 245-questionnaire sent, 223 were responded. The data gathered was then analyzed based on respondent's feedback with Structural equation modeling (SEM) technique using SmartPLS Application. The questionnaire was divided into 2 sections; Section A (demographic information), Section B; consist of the latent variables used for the study (information about performance expectancy, effort expectancy, social influence, facilitating condition, behavioral intention and use behavior). To ensure the content validity of the scales, all the items used to measure the variables were drawn from previous studies related to technology acceptance (Venkatesh et al., 2003; Compeau & Higgins, 1995; Moore & Benbassat, 1991; Thompson, Higgins & Howell, 1991). Respondents were asked to indicate their agreement or disagreement with several statements on a five-point likert scale ranging from 1 = strongly disagree to 5 = strongly agree.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.1. Data Analysis and Results

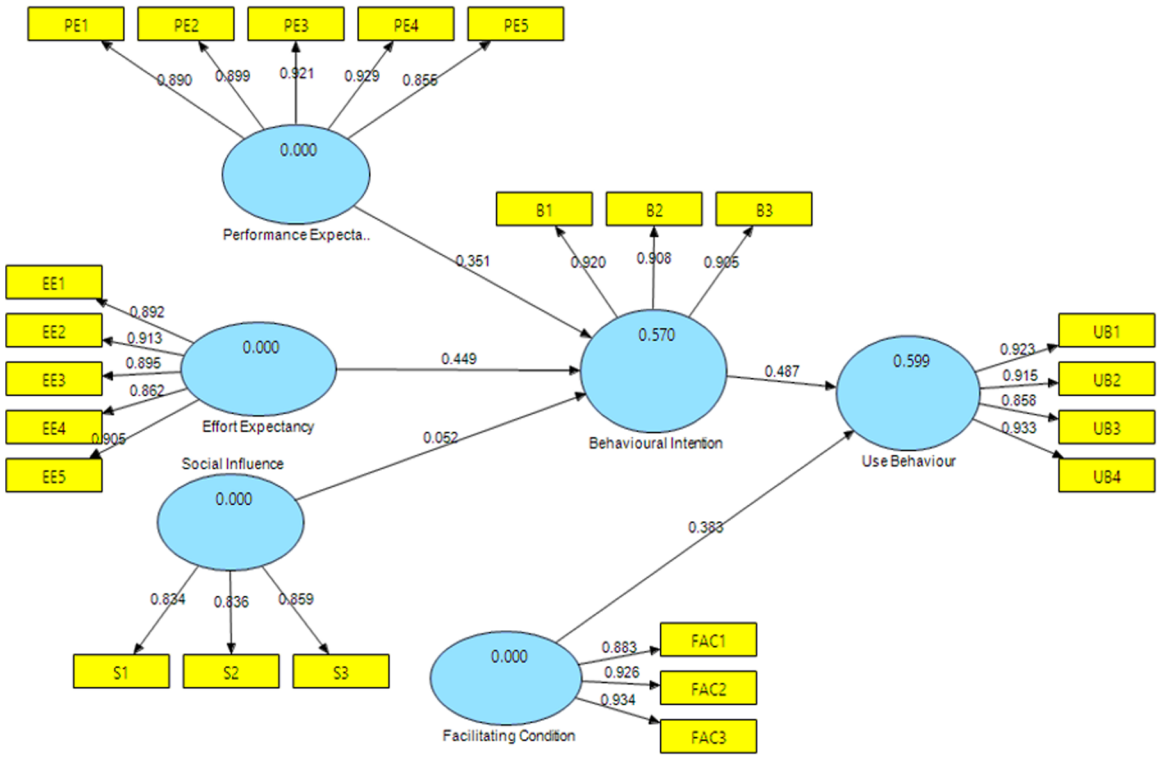
The analysis of the study was conducted in three phases. The first phase tested the measurement model (Figure 2) to examine the reliability and validity of variables. The second phase tested the structural model which also examined the relationships and hypotheses of the variables; and the final stage tested the moderating effect of gender on three independent variables. The measurement and structural model were recommended by Hair et al. (2017) and Rahman et al. (2016) to help researchers to test their respective models.

4.2. Measurement Model

4.2.1. Reliability (Indicator, Cronbach's Alpha, Composite)

The study first assessed the reliability of the model. Three forms of reliability were used, namely; indicator reliability, composite reliability and Cronbach's alpha. Indicator reliability was computed by finding the square of each of the outer loadings (items). Much acceptable value for indicator reliability should be value larger than the minimum acceptable level of 0.4 and close to the preferred level of 0.7 (Hulland, 1999; Hair et al., 2012). This was done to remove items that may not contribute significantly to the study (Table 1). Cronbach's alpha and composite reliability were used to assess the inner consistency of the measurement model. Although both are good measurement model. In PLS-SEM, previous literature

Figure 2. Path model (measurement model results)



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Summary of results

Latent variables	Indicators	Factor Loadings	Indicator Reliability (i.e. loadings^2)	Cronbach's Alpha	Composite Reliability
Behavioral Intention	B1	0.9204	0.8472	0.8983	0.9363
	B2	0.9084	0.8253		
	B3	0.9053	0.8196		
Effort Expectancy	EE1	0.8922	0.7960	0.9368	0.9519
	EE2	0.9132	0.8340		
	EE3	0.8949	0.8009		
	EE4	0.8619	0.7428		
	EE5	0.9046	0.8183		
Facilitating Condition	FAC1	0.8829	0.7795	0.9020	0.9547
	FAC2	0.9260	0.8575		
	FAC3	0.9340	0.8723		
Performance Expectancy	PE1	0.8903	0.7926	0.9405	0.9547
	PE2	0.8991	0.8084		
	PE3	0.9212	0.8486		
	PE4	0.9285	0.8621		
	PE5	0.8546	0.7304		
Social influence	S1	0.8338	0.6952	0.8191	0.8804
	S2	0.8363	0.6995		
	S3	0.8585	0.7370		
Use behavior	UB1	0.9230	0.8521	0.9285	0.9493
	UB2	0.9145	0.8364		
	UB3	0.8584	0.7369		
	UB4	0.9334	0.8713		

has suggested the use of composite reliability as a replacement of Cronbach's Alpha (Hair et al., 2012; Wong, 2013; Bagozzi & Yi, 1988). This is because, Cronbach's Alpha do not check for consistency of each indicator (item) but rather check the consistency for the combined indicators (Hair et al., 2013). As per Hair et al. (2014), the cut-off score for composite reliability is 0.7 and that of Cronbach's Alpha should be above 0.6 (Chin et al., 2003). As indicated in Table 1, the Cronbach's alpha value is above 0.6, and composite reliability value is more than 0.7. Hence, the model can be said as reliable or dependable.

4.2.2. Validity (Convergent, Discriminant)

The study also checked for convergent and Discriminant validity. Convergent validity specifies that items that are indicators of a construct should share a high proportion of variance (Wong, 2013; Hair el al., 2006). To check convergent validity, each latent variable's Average Variance Extracted (AVE) is evaluated. Average variance extracted (AVE) for each construct should be above the recommended cut-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

off 0.50 (Bagozzi & Yi, 1988; Fornell & Larker, 1981). From Table 2, it was found that all of the AVE values are greater than the acceptable threshold of 0.5, so convergent validity is confirmed. Discriminant validity which was also assessed, reflects the degree to which any single construct is unique and not simply a reflection of other variables (Hulland, 1999). As per Fornell and Larcker (1981), discriminant validity is obtained by calculating the square root of AVE, and if the values are larger the other correlation values among the latent variables. To do this, a table is created in which the square root of AVE is computed manually and written in bold on the diagonal of a correlation table between the latent variables (as seen in Table 3).

Table 3. Convergent and discriminant validity

	AVE	Behavioral Intention	Effort Expectancy	Facilitating Condition	Performance Expectancy	Social Influence	Use Behavior
Behavioral Intention	0.8307	**0.9114**					
Effort Expectancy	0.7984	0.6968	**0.8935**				
Facilitating Condition	0.8364	0.5726	0.6995	**0.9145**			
Performance Expectancy	0.8084	0.6600	0.6257	0.5928	**0.8991**		
Social Influence	0.7106	0.4844	0.5394	0.6797	0.5424	**0.8429**	
Use Behavior	0.8242	0.7069	0.7231	0.6624	0.6533	0.6368	**0.9078**

From the above Table 3, the latent variable Effort Expectancy AVE is found to be 0.798, hence its square root becomes 0.8935. This number is larger than the correlation values in the column of effort expectancy (0.6995, 0.6257, 0.5394 and 0.7231) and also larger than those in the row of effort expectancy (0.6968). Similar observation is also made for the latent variables performance expectancy, facilitating condition, social influence, behavioral intention and use behavior. The result indicates that discriminant validity is well established.

4.2.3. Structural Model Assessment

The study computed the T-statistics to check for the significance of the model using a procedure called bootstrapping (Figure 3) in SmartPLS. In this procedure, a large number of subsamples (e.g., 5000) are taken from the original sample with replacement to give bootstrap standard errors, which in turn gives approximate T-values for significance testing of the structural path (Wong, 2013). The Bootstrap result, however, approximates the normality of data. Path coefficient assessment is included in the structural model indicating the power of the relations among the R-square value and the latent variables (both independent and dependent variable). A 5% significance level ($p < 0.05$) is used as a statistical conclusion measure. The level of significance was determined by the use of the t-values. As indicated by Hair et al. (2013), t-values greater than the cut-off criteria (1.96) reflects significance in the model. Table 4 provides the summary of the results.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 3. Bootstrapping results

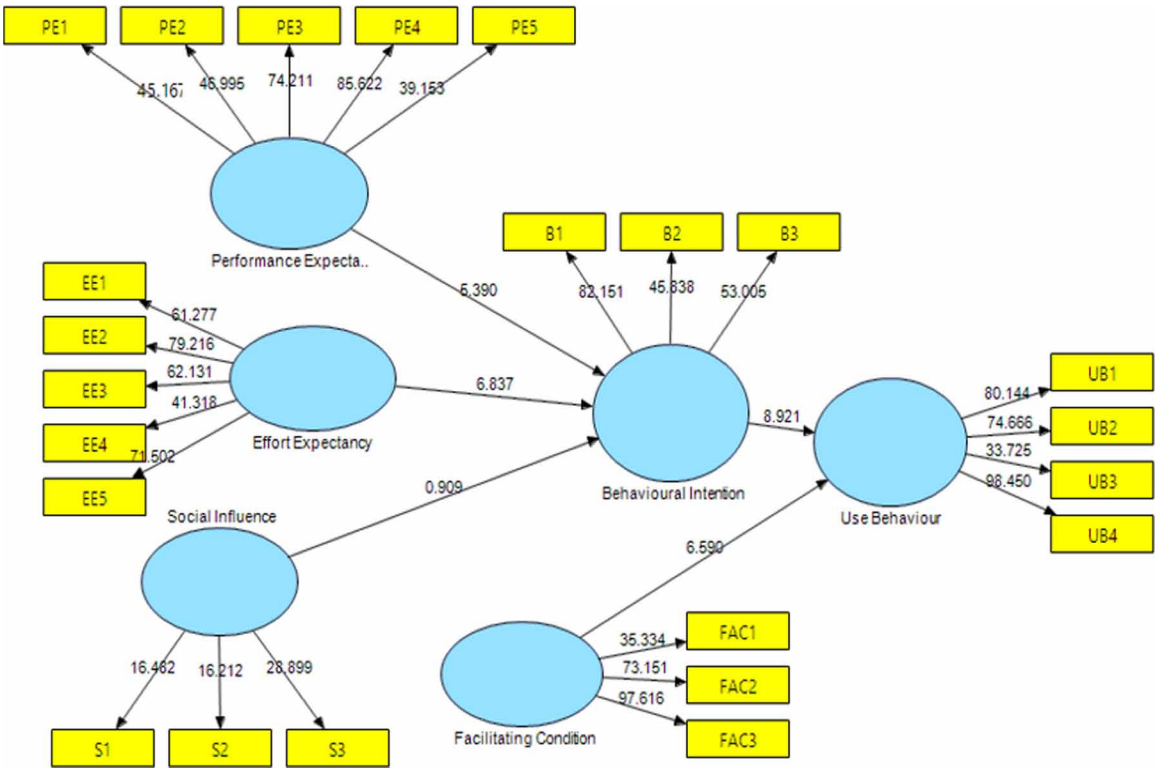


Table 4. Results of the hypothesis testing

HP	RLS	Original Sample (O)	Sample Mean (M)	Standard Deviation (STDEV)	Standard Error (STERR)	T -Value	Decision
H1	PE -> BI	0.3506	0.3489	0.0664	0.0664	5.2737	Supported**
H2	EE-> BI	0.4494	0.4530	0.0653	0.0653	6.8761	Supported**
H3	SI -> BI	0.0517	0.0506	0.0571	0.0571	0.9057	Not supported
H4	FC-> UB	0.3832	0.3856	0.0600	0.0600	6.3857	Supported**
H5	BI -> UB	0.4874	0.4855	0.0570	0.0570	8.5426	Supported**
	BI (R^2) = 0.5697 ≈ 0.57			UB (R^2) = 0.5985 ≈ 0.60			

*p < 0.10; **p < 0.05; ***p < 0.01; BI = Behavioral Intention UB = Use Behavior FC = Facilitating Condition SI= social Influence; PE = Performance Expectancy EF = Effort Expectancy; HP = Hypothesis RLS = relationship

The analysis shows (Figure 2, Table 3) that performance expectancy (PE), effort expectancy and social influence together can explain 57% of the variance in behavioral intention. Also, facilitating condition and behavioral intention together explains 60% of the variance in use behavior. Hypothesis H1 states that performance expectancy will positively affect lecturers' intention to adopt e-commerce system. From Table 3, the hypothesis path for H1 was positive and significant ($\beta = 0.3506$, $P < 0.05$). This indicates that lecturers' intention to adopt e-commerce is influenced directly and positively by

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

performance expectancy. Hence, hypothesis H1 is supported. Hypothesis H2 suggests that effort expectancy has a positive relationship on lecturers' intentions to adopt e-commerce system. The hypothesis path for H2 was positive and significant ($\beta = 0.4494$, $P < 0.05$). This indicates that lecturers' intention to adopt e-commerce is influenced directly and positively by effort expectancy. Hence, hypothesis H2 is supported. The relationship between social influence and lecturers' behavioral intention was not supported and insignificant with $\beta = 0.0517$ and $t = 0.9057$, indicating that social influence has no much significant with lecturers' intention to adopt e-commerce system. Hence, hypothesis H3 is not supported. Hypothesis H4 suggests that facilitating condition has a positive relationship on lecturers' intentions to adopt e-commerce system. The hypothesis path for H4 was positive and significant ($\beta = 0.3832$, $P < 0.05$). This indicates that lecturers' intention to adopt e-commerce is influenced directly and positively by facilitating condition. Hence, hypothesis H4 is supported. The relationship between behavioral intention and lecturers' use behavior was supported and significant with $\beta = 0.4874$and $t = 8.5426$, indicating that lecturers' behavioral intention to adopt e-commerce system is positively influenced by the user behavior. Hence, hypothesis H5 is supported.

4.2.4. Model Accuracy and Usefulness

The study also evaluated the model accuracy and usefulness by using Stone-Geisser Indicator (Q^2) and Cohen's Indicator (f^2) (Hair et al., 2014). The Stone-Geisser Indicator (Q2) measures the model prediction quality or significance model. As per Hair et al. (2014), to obtain a good prediction quality, indicator value greater than zero should be obtained. However, a perfect model would have $Q^2 = 1$, which indicates the model reflects reality and without any errors. Also, Cohen's Indicator (f^2) measures the usefulness of each construct. For Cohen's Indicator (f^2), Values of 0.02, 0.15 and 0.35 are considered small, medium, and large respectively (Hair et al., 2014). Table 4 shows that the values of Q^2, as well as those of f^2, indicate that the model is accurate and that the constructs are important for the general adjustment of the model.

Table 5. Values for Stone-Geisser Indicator (Q^2) and Cohen's Indicator (f^2)

Construct/variable	CV RED (Q^2)	CV COM (f^2)
Behavioral Intention	0.458518	0.622541
Effort Expectancy	0.687333	0.687333
Facilitating condition	0.633447	0.633447
Use behavior	0.491538	0.687263
Performance Expectancy	0.701884	0.701884
Social Influence	0.397532	0.397532
	$Q^2 > 0$	**f^2** > {0.02, 0.15 and 0.35 are considered small, medium and large}

4.3. Moderating Effect of Gender

This study further investigated the moderating effect of gender on the relationship between the exogenous latent variable (performance expectancy (PE), effort expectancy (EE), Social Influence (SI)) and the endogenous latent variable (Behavioral Intention (BI)). The results indicate that gender has no moderating effect on PE, EE and SI. Although the relationship between PE and BI; and EE and BI were found to be statistically significant, moderating these variables with gender was found to be statistically insignificant. Figure 4 presents the model with gender as moderator. Table 5, also presents summary of the bootstrapping results.

Figure 4. Moderating effect of gender

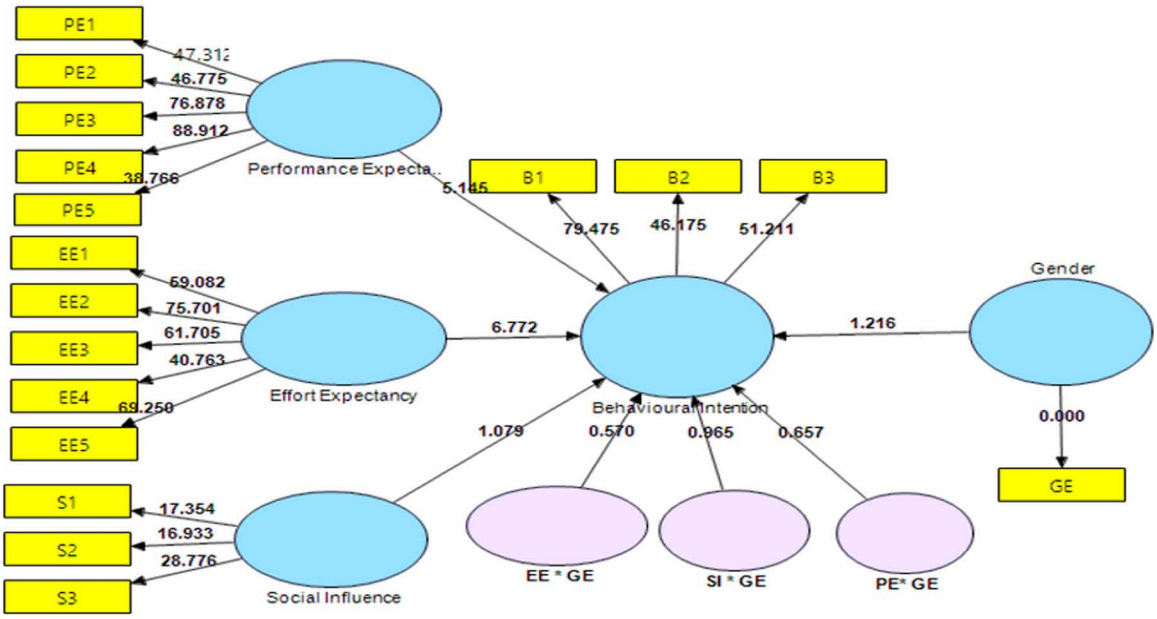

Table 6. Results of the hypothesis testing

Hypotheses	Relationship	Effect Type	T - Value	Decision
H6	Gender × (EE) -> BI	Moderating effect	0.570011	Not supported
	EE -> BI	Normal effect	6.771708	Supported**
	Gender -> BI	Normal effect	1.216253	Not supported
H7	Gender × (PE) -> BI	Moderating effect	0.657380	Not supported
	PE -> BI	Normal effect	5.144652	Supported**
H8	Gender × (SI) -> BI	Moderating effect	0.964780	Not supported
	SI -> BI	Normal effect	1.078820	Not supported

5. DISCUSSION OF FINDINGS

By using the unified theory of acceptance and use of technology (UTAUT), this study enriched our understanding e-commerce systems adoptions factors and the moderating effect of gender on the adoption factors. The study results (Table 6) showed that a significant amount of variance in the use behavior is explained by the independent variables used in this study.

5.1. Hypotheses 1-5

The first hypothesis stated that performance expectancy (PE) will positively affect lecturers' intention to adopt e-commerce systems. Results from the PLS-SEM indicated a positive and significant relationship between PE and behavioral intention to use e-commerce systems by lecturers in Ghana. This shows support for H1 and concurs with Abrahao et al. (2016) whose study revealed that perceived expectancy has a positive and significant relationship with the intention to adopt mobile payment. Yu (2012) also found perceived expectancy to be a positive and significant factor affecting individual adoption of mobile banking.

The second hypothesis stated that effort expectancy (EE) will positively affect lecturers' intention to adopt e-commerce systems. Again, results from the PLS-SEM showed a positive and significant relationship between EE and behavioral intention to use e-commerce systems by lecturers in Ghana. The same effect is found in the works of Chong (2013), Barbosa and Zilber (2013), Oye et al. (2014) and Martins et al. (2014), where it was singled out as one of the greatest determinants of intention to adopt the technology. However, it contrasts Gouveia & Coelho (2007), who did not show this variable as a relevant factor.

This study further hypothesized that social influence (SI) will positively affect lecturers' intention to adopt e-commerce systems. The results from the analysis did not show support for SI. There was an insignificant relationship between SI and behavioral intention to use e-commerce systems by lecturers in Ghana. The same effect is found in the work of Suki & Suki (2017), where it was found that social influence had insignificant effect on students' behavioral intention to adopt a technology. This contrasts Yu (2012) and Sripalawat et al. (2010) whose study indicates that the social influence is the most powerful factor in affecting people intention to use mobile banking. Contrary to the findings of this current paper, Abrahao et al. (2016) analysis of the social influence factor also proved to be relevant and with a positive relationship in the prediction of behavioral intention in the same way that Gouveia and Coelho (2007), Oye et al. (2014) and Martins et al. (2014). Unlike this current study with a focus on a developing country, the aforementioned studies were conducted in the more developed contexts. Accordingly, the difference in culture may have played a major role in the disparity of the finding on social influence which is worthwhile to be further analyzed.

The fourth hypothesis stated facilitating conditions will positively affect lecturers' use behavior of e-commerce systems. The results revealed that facilitating conditions were a significant and a positive contributing predictor of lecturers use behavior of e-commerce systems. This finding was consistent with the research Suki & Suki (2017) whose research indicated that facilitating conditions have a positive effect on students' behavioral intention to use and the actual usage of a technology.

The fifth hypothesis stated that behavioral intention will positively affect lecturers' user behavior to adopt e-commerce systems. Indeed, Ghanaian lecturer's actual use of e-commerce systems was also

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

influenced by their behavioral intention to use it. Hence, H5 was upheld. This is corroborating Brom et al. (2011) and Norazah & Norbayah (2016).

5.2. Hypotheses 6-8

H6 stated that the influence on performance expectancy on Ghanaian lecturers' intention to adopt e-commerce systems will be moderated by gender. H7 also stated the influence on effort expectancy on Ghanaian lecturers' intention to adopt e-commerce systems will be moderated by gender. Furthermore, H8 proposed the influence on social influence on Ghanaian lecturers' intention to adopt e-commerce systems will be moderated by gender. However, results from the PLS-SEM showed an insignificant relationship between gender and performance expectancy, effort expectancy and social influence. This indicates that gender has no moderating effect of PE, EE and SI on Ghanaian lecturers' intention to adopt e-commerce systems. This is somewhat surprising but not totally unexpected. This contrast the study of Hasan (2010), who found that online shopping attitude is higher in men than women. Yates (2001) also found computer- mediation communication to be higher in men than women. Different cultural settings might be a factor for this kind of disparity.

6. LIMITATIONS OF THE STUDY AND SUGGESTIONS FOR FUTURE RESEARCH

This research was not without some limitations. First, it is unknown how well the model and its findings will be generalized beyond the specific conditions of this study, since we adopted only university lecturers as sample. Future research is needed to better comprehend how well the model generalizes to e-commerce systems adopter with different background. Second, the current study did not include other possible moderating variables, such as experience, but included gender in the model. However, given that gender is the most important aspect of systems adoption and communication behavior (Tannen, 1991; Yates, 2001), we argue that gender should be investigated further. Future study can test the relationships with other moderating variables.

7. CONCLUSION

This study investigates the moderating effect of gender on e-commerce systems adoption factors using the unified theory of acceptance and use of technology (UTAUT). In the analysis of 223 samples, performance expectancy, effort expectancy and facilitating conditions had a positive and significant relationship with behavioral intention to adopt e-commerce systems. Social influence on the other hand had an insignificant relationship with behavioral intention to adopt e-commerce systems. Behavioral intention also showed a significant relationship with actual use of e-commerce systems, indicating that lecturers' behavioral intention to adopt e-commerce system is positively influenced by the user behavior. Moderating performance expectancy, effort expectancy and social influence with gender, the PLS-SEM analysis indicate gender has no moderating effect on any of the factors it moderated. The findings of this study will be helpful for e-commerce researchers and practitioners in understanding online consumers' behaviors, which is essential for successful e-commerce systems implementation.

Chapter 18
Study on E-Commerce Adoption in SMEs Under the Institutional Perspective: The Case of Saudi Arabia

ABSTRACT

This article investigates and discusses the institutional factors influencing decisions of e-commerce adoption in Saudi small and medium enterprises (SMEs) from the temporal view. This article has been conducted in two phases: a full survey in 2013 and the follow-up targeted interviews in 2016. The analysis results demonstrated that there is a clear difference between initial e-commerce adoption and institutionalization in SMEs in terms of institutional predictors. When e-commerce was at its infant stage, governmental support and well-defined legal and regulations system were instrumental and served as mainly institutional forces to encourage firms to adopt e-commerce. As time went on and e-commerce became more business-driven, these effects become less important, even insignificant; instead of these, perceived market forces and perceived social awareness of e-commerce emerges as critical contributions to push SMEs to engage in e-commerce more sophisticatedly.

INTRODUCTION

The literature on e-commerce empirically reveals that e-commerce adoption brings potentially benefits to SMEs (Tran et al., 2013). E-commerce in general bridges the physical and time-dependent distance between suppliers and customers, enhances the efficiency and flexibility of production and operation, reduces market entry barriers, and increases the competitiveness of markets. However, its adoption by SMEs remains limited. For example, a previous survey found that 36% of small businesses established web sites primarily to advertise and promote their business, compared to 9% who established one to sell or market online. Similarly, a survey of 444 SMEs found that many SMEs were reluctant to conduct transactions on line; more than 80% were only using the Internet to communicate (via e-mail) and gather business information (Zhu, 2008). Al-Qirim (2008) found that the main barriers or concerns inhibiting SMEs from adopting e-commerce are: non-adopted customers/suppliers, violated privacy and security issues, lack of expertise or personnel, lack of belief that online marketing would be effective, high costs, and technical limitations of hardware or software.

Although the King of Saudi Arabia (KSA) has the largest and fastest growth of Information Communication Technology (ICT) marketplaces in the Arab region, the diffusion and the rate of B2B e-commerce sophistication in SMEs are actually very low, and not parallel with the remarkable development of the e-business infrastructure (AlGhamdi et al., 2012). The challenge for policy-makers is therefore to better understand the e-commerce phenomenon and to ensure that the opportunity and potential offered by e-commerce is taken and realized in SMEs. There has been a long-standing debate and different approaches on how an enabling environment should be created and shaped to foster e-commerce adoption and diffusion. Additionally, the existing literature is lacking studies to focus on investigation of various determinants of decisions of e-commerce adoption at the different levels. Tran et al. (2014) and Molla & Licker (2005) provided empirical evidence showing that the determinants of initial adoption of e-commerce are very different from those of institutionalization of the technology. The experience of the initial adoption of e-commerce is also found not to have any significant effect on the decision of subsequent implementation of the technology.

Therefore, the purpose of the study is to investigate institutional factors affecting decisions of e-commerce adoption in Saudi SMEs from the temporal view. To address this objective, a conceptual model was developed based on the institutional perspective. This study has been conducted in Saudi Arabia in two phases. Phase I was in 2013 with a full survey and phase II was in 2016 with the follow-up targeted interviews. Data collected was analyzed to investigate whether determinants of e-commerce adoption in SEMs are different at maturity levels and change over time.

THE THEORETICAL BACKGROUND

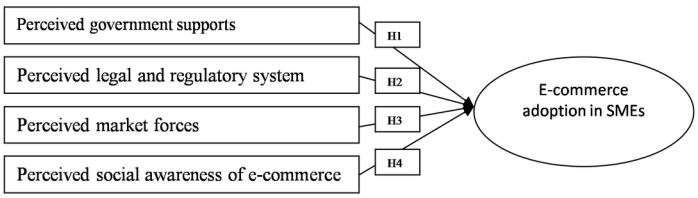
The conceptual research framework was developed based on the institutional theory (Figure 1). The institutional theory provides a rich, complex view of organizations; organizations are open systems and the institutional context is a major source of influence on organizational behavior. Accordingly, in order to understand individual and organizational behavior, it must be located in a social and institutional context, and this context both regularizes behaviors and provides opportunity for agency and change. Institutional theory posits that pressures from industrial, political, legal and cultural systems, and expectations from society define what is socially acceptable and expected organizational behavior, which

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

pressures organizations to look and act the same. In viewing institutions more widely as varied social constructs, including cultural beliefs, new institutionalism has moved away from its formal legal historical roots and become a more explanatory discipline in economics and social sciences. Contemporary institutional theory focuses on developing a sociological view of institutions -the way they interact and the way they affect society (Scott, 2005).

There is substantial evidence in economics that firms in different institutional environments react differently to similar challenges and that companies can perform efficiently if they receive the institutional support (Gosain, 2004). The limited studies of IT adoption and diffusion in the last decade have also suggested that a supportive institutional environment and a variety of nurturing policies from governments are especially indispensable for technological innovation. Therefore, this study considered five independent institutional constructs: perceived government supports, perceived legal and regulatory system, perceived market forces, and perceived social awareness of e-commerce.

Figure 1. Research framework and hypotheses



The dependent variables, e-commerce initial adoption, and intention for e-commerce institutionalization are posited as the primary constructs of SMEs' adoption of e-commerce at different levels. Based on the literature, the level of e-commerce adoption should be considered through the sophistication in terms of management, function, technology, and information, and the usage degree of e-commerce innovation by enterprises. In other words, the level of e-commerce adoption is a product of sophistication level by usage degree. Since the first stages of e-commerce adoption process is very simple while its last stages are much more sophisticated and complicated in terms of technology and management, consequently, the first stages are also very different from the last stages in terms of demand of technology infrastructure, management, and other resources. In order to effectively implement e-commerce at the more sophisticated level, one certain enterprise needs to reach a much higher e-readiness in terms of both external and internal environments. In this study, instead of studying the process of e-commerce adoption on many different stages, it investigated determinants of e-commerce adoption at two key levels, namely initial adoption versus institutionalization.

Initial adoption is referred as the simple level of e-commerce adoption with the low sophistication level and the low degree of usage. One enterprise is considered as in the initial adoption level if it has been implementing only one or several simple e-commerce innovations separately for a small part of the total business transactions and has been using only the static or interactive websites to make promotions and publish basic company information or receive queries, e-mail, and form entry from users (Molla & Licker, 2005; Tran et al., 2014).

Institutionalization is referred as the most sophisticated adoption of e-commerce. One enterprise is considered to be in the institutionalization stage if it has an integrated e-commerce system with external

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

business partners and existing organizational systems, and most business processes conducted electronically. It means that the enterprise has implemented many different e-commerce innovations, most its B2B business processes have been conducting electronically, e-commerce innovations implemented having a good interoperability together, and with other existing IT systems, and e-commerce innovations implemented have a good interoperability with external IT infrastructure through transactive or integrated websites, and e-marketplace. Especially, based on the literature on Information Systems alignment, institutionalization of e-commerce should also be reflected through the degree of consistency between e-commerce strategy with business strategy, organizational structure, and social environment within the enterprise (Chiang & Nunez, 2013).

DEVELOPMENT OF HYPOTHESES AND CONSTRUCTS

Perceived Government Supports

Government support takes various forms from country to country; however, the institution theory indicated that governments played a critical role in creating the institutional environment that fostered private investment and e-commerce in particular (Oxley & Yeung, 2001). For e-commerce to succeed, the economy needs to be competitiveness, transparency, stableness; trend of collaboration and cooperation.

Policies and Commitments for National E-Commerce

Al-Rawi et al. (2008) reviewed and explored e-commerce growth in the Gulf region and they found that the governments' roles in promoting e-commerce is essential in terms of ensuring coherent policy for IT and e-commerce regarding consumer protection; secure, transparent, predictable, and enabled environment; coordination, collaboration, and cooperation. The European Commission's report suggested that governmental policies aiming at promoting e-commerce should include creating incentives and a favorable environment for enterprises; supporting educational and training programs; and establishing the role model of the public sector. It is argued that national policies for e-commerce, such as trade and telecommunication liberalization, training and maintaining an adequate e-commerce workforce, were likely to have a big impact on e-commerce by making IT more affordable to firms (AlGhamdi et al., 2012). Government's role in supporting e-commerce adoption in the private sector has been referred to as a leader, promoter, facilitator, regulator, educator and financiers.

E-Government Initiatives

In less developed or developing countries, competitive environment is often determined by the relationship between businesses and government, and business managers in SMEs often trend to be directed by government and less willing to accept changes (Huang et al., 2014). Once e-government initiatives are implemented, government's role often changes from simply informational to transactional. As a result, the government becomes both supplier and consumer therefore contributing to the growth of e-commerce (Huang et al., 2014).

In Australia, the Government is providing support in various forms; for example, hosting an online retail forum to encourage, assist and inform retailers. The Hong Kong ordinance contributed to future

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

growth in e-commerce by providing for a legal infrastructure, such as the use digital signatures. It is stated that the Brazilian e-government initiatives, such as e-services and e-procurement have strongly stimulated e-commerce activities in the private sector. In many other countries, such as Denmark, France, the effectiveness of government supports in building consumer acceptance of IT as well as developing IT literacy to promote IT and e-commerce in businesses, especially SMEs was recorded (Gibbs & Kraemer, 2004).

Regarding SMEs, Lip-Sam & Hock-Eam (2011) and Jeon et al. (2006) found empirically that government support was effective factor for e-commerce adoption at all adoption levels in SMEs. When asked to identify the measures to encourage wider adoption and use of ecommerce, SMEs in the APEC region highly ranked government actions in improving telecom infrastructure, imposing fair tax policy for online transactions, developing national e-commerce strategy, enhancing government e-commerce use, providing e-commerce training, and promoting e-commerce use.

However, there were some contradictory findings in previous literatures with respect to governmental support. Ifinedo (2011) found that government support were not significant for the e-commerce adoption of SMEs in Canada. Governmental support was also not regarded as a driving factor for e-commerce adoption in USA (Chong et al., 2009). It was also found insignificant in differing groups of firms between Internet adopters and non-adopters in Singapore (Teo et al., 2009), in affecting the success level of e-commerce among SMEs in IT industry of Taiwan (Huang, 2009), and in the probability of e-commerce adoption of SMEs in Brunei (AlGhamdi et al., 2012). Therefore, we propose:

Hypothesis 1: Government support contributes significantly (and is positively related) to (a) initial adoption of e-commerce and (b) institutionalization in SMEs.

Perceived Legal and Regulations System

The legal consideration was the root of traditional institutional theory. Institutions were first the legal ground rules and procedures. Institutional influences were therefore political in nature as when organizations must conform to laws and regulations to earn the organizational legitimacy (Yuan et al., 2012). A well-defined legal framework is positively related to ensuring the security of e-commerce activities, and improves trust in e-transactions (Kim, 2005). The lack of legal framework for e-commerce in a country causes consumers to have significant reservations on purchasing online (Gibbs & Kraemer, 2004). The consumers' concerns regarding trust in business practices, privacy/security, and "resistance to using credit cards, and preferences for in-store shopping and inspection of products" become greater in an environment where the legal framework is less established (Gibbs & Kraemer, 2004).

Several international studies using secondary data found that the legal environment in a country significantly affected e-commerce activities and revenues in that country (Oxley & Yeung, 2001). A group of firm-level survey studies also showed that the regulatory environment was significantly important to determine both the breadth and depth of e-business adoption and drive the e-business value, especially in developing countries and newly industrialized economies (Gibbs & Kraemer, 2004). Another study of more than 100 SMEs in the state of Kentucky showed that regulations and rules were an important factor for e-commerce adoption (Kim, 2005). In addition, the implementation of e-commerce systems at the more sophisticated level demands even a more well-defined legal and regulatory system. Therefore, we propose:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Hypotheses 2: Legal and regulations system have significant effects on (a) initial adoption and (b) institutionalization of e-commerce in SMEs.

Perceived Market Forces

E-commerce activities respond to the network principles in the social-business system of the enterprise (Molla & Licker, 2005). In other words, firms' potential for e-commerce is a function of their operating environment, including economic, social, and political factors. Organizations that perceive institutional pressures as ready for e-commerce are likely to adopt e-commerce or implement e-commerce at the more sophisticated level (Rogers, 1995). The level of take-up by suppliers and customers may have a corresponding effect on a firm's commitment to e-commerce. However, it is argued that such pressures tend to be less likely for some businesses in developing or less developed countries' context. For SMEs in relationships with large firms, the motivation to adopt is fueled by the integration of trading partners into organizational extranets (Zhu & Kraemer, 2005). Large companies are increasingly outsourcing many of their requirements, and e-enabled SMEs have the ability to respond more quickly to changing demands than their large counterparts enabling them to take advantage of outsourcing opportunities (Featherman & Pavlou, 2003).

A recent comprehensive study on SMEs in Denmark, Germany, France and the U.S. found that important drivers for e-commerce diffusion in manufacturing, retail/wholesale and financial service sectors included the use of e-commerce by major competitors, customer demand, and supplier requirements. The European Commission's e-Business Survey 2006 found that four main reasons for companies to start e-commerce were: "because competitors use it," "to gain competitive advantage," "to fulfill customers' expectations," and "to fulfill suppliers' expectations," which in summary represented competition pressure and market demand (Batenburg, 2007). Furthermore, policy-makers, industry practitioners and academic researchers, especially those in the U.S., strongly believed that while the government had an important role to play in setting the proper business climate to promote innovation, e-commerce development should be guided principally by market competition, market choice and industry leadership (Zhu & Kraemer, 2005). Several key dimensions of the market force identified in the literature review are discussed including (1) Competitive pressure, (2) Pressure/encouragement from customer/supplier, (3) Pressure/encouragement from trend-setting firms; and (4) Pressure/encouragement from industry/trade associations.

Competitive Pressure

Competitive pressure refers to the situations of marketplace where there are firms running similar businesses in competition with each other. In relation to e-commerce, this refers to the situation where selling online successfully and profitably can affect market share in the traditional marketplace (To & Ngai, 2006).

Pressure exerted by competitors' use of e-commerce was empirically a main driver of e-commerce adoption decisions among firms in Hong Kong (Gunasekaran & Ngai, 2008). When surveying more than 270 companies across three industries in ten countries, Gibbs et al. found the pressure from competitors was a significant determinant of scope of e-commerce use (Gibbs & Kraemer, 2004). Pressures from an enterprise's external business environment (suppliers, clients, competitors, and partners) were found as the most significant factor affecting the level of institutionalization of e-commerce adoption in developing countries (Molla & Licker, 2005).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The findings about competitive pressure in the literature review, however, were not always consistent. The importance of competition was only marginal in e-commerce adoption among large public firms in India (Tarafdar & Vaidya, 2006). In a cross-country survey of retail industry, Zhu et al. found that competitive pressure was a significant factor for use of e-commerce only in developed countries, but not in developing countries (Zhu & Kraemer, 2005). Lastly, competition was not so important to the e-commerce starters and late adopters as to those extended adopters in New Zealand (Al-Qirim, 2008).

In Saudi Arabia, the reviewed literature does not record competition as an influencing factor in the adoption of e-commerce. Because of the lack of maturity of online business environments in the country, the convenience of traditional shops nearby and there is no competitive pressure on the Internet (AlGhamdi et al., 2012).

Pressure/Encouragement From Customers/Suppliers

Trading partners could be a dominant customer (or supplier) pushing its suppliers (or customers) to implement relationship-specific information systems. Several empirical studies have proved a positive relationship between trading partner's pressure and e-commerce adoption among SMEs in Singapore, and South Korea (Teo et al., 2003). Both traditional and IT manufacturers in SMEs in Hong Kong claimed that customer pressure was the primary motivator for them to adopt e-commerce (Ghobakhloo et al., 2011). Furthermore, SMEs participated in an APEC's e-commerce survey ranked "low use of e-commerce by customers and suppliers" as the No.1 perceived barrier to e-commerce adoption (Luqman & Abdullah, 2011). On the other side, although it was most important for the diversity of e-commerce usage, pressure from trading partners was not significantly important for e-commerce transaction volume in US companies (Kiong, 2004). Moreover, Chan et al. surveyed 627 SMEs in manufacturing and trading industries in Hong Kong and found 74 trading partners' influence to be totally opposite: compared with non-adopters, those EDI adopters considered the request by trading partners significantly less important (Chan et al., 2012).

Pressure/Encouragement From Industry/Trade Associations

Industry or trade associations have been strong promoters of B2B e-commerce, especially to SMEs, by providing them technical support, training and funding (Gibbs & Kraemer, 2004). For example, based on 50 qualitative interviews in multiple countries, it is found that trade and industry associations played an important role in promoting e-commerce in southeastern Europe (To & Ngai, 2006). Those associations also involved actively in setting up the industrial e-commerce standards. Their level of involvement and their actions were critical in launching an industry-wide use of IT. A contradictory finding in a survey of 137 CEOs showed no significant effect of trade association on e-commerce adoption in Taiwan's travel service industry (Wang et al., 2010). Drawing on the theoretical and empirical arguments, this study hypothesized that institutional pressures (from competitors, customers/suppliers, and industry associations) had a positive influence on a firm's e-commerce adoption, as follows:

Hypothesis 3: Perceived market force has significant effects on (a) initial adoption and (b) institutionalization of e-commerce in SMEs.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perceived Social Awareness of E-Commerce

The socio-culture environment should be of positive trust, beliefs, concepts, judgments, expectations, and methodologies towards e-commerce (Huang et al., 2014). Information sharing among organizations and between businesses with government is indispensable. All players need to have a positive perception of the role of information and positive attitudes toward IT and e-commerce. An information-sharing incentive industrial culture is more important for the development of e-commerce in developing or less developed countries. Social awareness of e-commerce represents social culture, knowledge, and attitudes of the industry toward e-commerce. It includes four facets: (1) industrial economic characteristics (i.e., competitiveness, transparency, stableness, trend of collaboration, and cooperation), (2) industrial socio-culture characteristics (i.e., trust, beliefs, concepts, judgments, expectations, and methodologies toward e-commerce) that are shared by people and enterprises within the industry, (3) industrial knowledge characteristics (i.e., perceptions of IT, skilled labor force, technicians, IT-oriented managers) required for the development of e-commerce strategy, and (4) industrial knowledge sharing infrastructure (i.e., initiatives available to share and develop knowledge and positive culture toward e-commerce (Ismail & Kamat, 2008; Zhu et al., 2006). E-commerce will benefit from online business educational programs and building the electronic services awareness in a country. Huang et al. (2014) found that government could mostly influence e-commerce diffusion through knowledge development including training programs, subsidies, and educational and informational campaigns to build the e-commerce awareness on nationwide. Therefore:

Hypotheses 4: Perceived social awareness of e-commerce significantly influences (a) initial adoption and (b) institutionalization of e-commerce in SMEs.

RESEARCH METHODOLOGY

This study used the explanatory mixed research method including first collecting quantitative data and then collecting qualitative data to help explain or elaborate on the quantitative results.

Data Sampling Procedures

Data Collection for the 2013 Quantitative Study

Data was collected in the King of Saudi Arabia (KSA) using a mixed sampling procedure Based on previous experience through the pilot study; it is highly difficult and takes long time to reach top managers in the Saudi enterprises using the common communications (e.g. email, letter, and calls without recommendation). In fact, the researcher has tried to find helps from several government officials but failed as they were not helpful. It is often that surveys via self-administered questionnaire through post or e-mail in the KSA gain a very low response rate; we used questionnaire survey administered in person in this study. The pilot study also confirmed that the questionnaire in person is appropriate for this situation.

Data collection was performed via a multistep process. Firstly, the website at http://www.saudiayp.com/category/Small_business accessed on 20 June 2013 which lists all 6909 small and medium enterprises in KSA, was used as an initial contact source. Next, researchers grouped all SMEs who have

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

their own websites listed in this page to make a new list of 762 SMEs that is considered as a sampling frame for this present study. At this point, the researchers used parallel two methods. One a hand, based on the random systemic sampling technique (every 5 items) we have collected 70 small and medium enterprises, and then an interview invitation email and the questionnaire were electronically sent out to them by the researchers to introduce the research project. Only 14 out of these seventy enterprises agreed to participate in the project.

On the other hand, the researchers used the help of twelve professors from the King of Saud University – College of Business Administration in Riyadh, the Kingdom of Saudi Arabia to reach enterprises. They provided a list of 62 managers from enterprises but only 32 managers from appropriate enterprises who belong to the population (i.e. small and medium firms having their own websites). Then, calls or emails were sent out to introduce the research project and ask interviews. There have been 25 out of the 32 managers agreed to participate in the project. In next step, the researchers made calls directly to the 39 firms (i.e. 14 ones from the first technique and 25 ones from the second method) who agreed previously to make an appointment (date and time) for interviews later. Then the researcher visited each enterprise and administered the questionnaire in person. After each initial interview, participants were asked to suggest other participants that might be willing to participate in the research and so on with other participants. The snowball process provided about 148 additional potential participants, and 94 out of them participated in the project. The entire process of selection provided 133 responses during two months from June to July, 2013.

Data Collection for the 2016 Interview Study

Within the initial invitation letter of the 2013 quantitative study, researchers not only asked the participants to take the survey, but also asked him/her to have a follow-up interview in next year. For the purpose of enhanced effectiveness of interview, all interviews averaged about forty-five minutes in length and were conducted in person. The interviews included discussion of the company's use of B2B ecommerce and the reasons behind such adoption decisions, following an interview guideline that was emailed to the interviewee for review at least 72 hours in advance. The interview guideline provided interviewees with a script that had a similar schedule in the survey so that interviewees had a good idea and confidence about the interview. Interviews were carried out in September 2016.

The interview procedure worked as follows. The author began with factual information about the kind of e-commerce technologies and/or activities the company was using and/or engaging in. The researchers next asked about the already and intended changes of e-commerce adoption within the company. The researchers then entered a group of questions about the industrial, governmental, legal and cultural effects on the company's e-commerce decision. Lastly, the researchers asked the interviewees to rank the importance of influential factors that affected their decisions of e-commerce adoption. The researchers also asked whether there was any contributing factor that the study had not mentioned yet. There have been nine enterprises agreed to participate the interview and in fact there have been a total of four interviews conducted.

Demographics of Respondents and Their Enterprise

As described above, the researchers have reached 250 SMEs (i.e. 70 firms from the random systemic sampling technique, 63 companies from the "personal introduction" sampling technique, and 148 ones

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

in the "snowball" method) to survey but only 137 completed questionnaires were collected, refined, and coded. Therefore, the response rate is 53%. Characteristics of demographic information of the respondents and their enterprises were analyzed and provided in Tables 1 and 2, respectively.

Table 1. Profile of respondents

Manager Gender		Manager Education		Position	
Male	90 (55%)	Ph.D.	5 people (4%)	Senior manager	37 (24%)
Female	47 (34%)	Master degree	64 people (55%)	Procurement manager	40(32%)
		Bachelor degree	68 people (41%)	Marketing manager	33 (24%)
				IT manager	10 (8%)
				Others	17 (9%)

Table 2. Profiles of enterprises

Business Sector		Number of Employee	
Manufacturing industry	59 firms (43%)	<20	12 (9%)
Service sector	56 firms (41%)	20-50	47 (34%)
Construction sector	15 firms (11%)	51-100	42 (30%)
Other industries	7 firms (5%)	>100	36 (27%)

All enterprises of the sample admitted that they have their own websites and use one or several of e-commerce innovations in business activities. It implies that all firms of the present sample should be considered as adopters. Considering the profile of the respondents and their enterprises, it can be said that the responses can be confidently relied upon. Table 3 shows the related information in detail.

Table 3. Category of firms in terms of the level of e-commerce adoption

Category	Simple E-Commerce Innovations Implemented	Many E-Commerce Innovations Implemented	Total
Static or interactive websites	98	33	129
Transactive or integrated websites and connect to e-platforms	0	6	6
Total	98	39	137

Data Screening

In order to address missing data, in this study, listwise deletion method was used, and there have been 4 uncompleted questionnaires deleted. Regarding multivariate analyses in correlations, SEM is very vulnerable to outliers (Hair et al., 2006). In this study, we used SPSS 19.0 calculating Cook's D to measure

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

multivariate outliers. There was no Cook's D larger than 1 from the regression; this means that there was no case for deletion.

It needs also to test whether or not statistical difference exists between the two sample groups: one used the English version of questionnaire and one used the Arabian version of questionnaire. In this study, independent-samples t test was used to compare demographic variables, such as managers' gender, manager' educational degree, business sector and employee number of enterprises from the two groups: (1) using the English version and (2) using the Arabian version. The descriptive statistics results indicated there was no difference in mean scores between the groups being compared; for example regards to gender $t(131) = 0.57$, $p = 0.57$, regards to business sector, $t(131) = 0.526$, $p = 0.60$. This means that there is no concern that responses sampled from the two versions of questionnaire to be different. Additionally, it need also to test whether or not statistical difference exists between the three sample groups: one group of 14 participants from the "random-systemic-selected"70-sample list, the second group of 25 participants from the "personal-introduction" 32-sample list, and the third group of 94 participants from the "snowball" 148-sample list. The independent-samples t test was also used to compare demographic variables, such as managers' gender, manager' educational degree, and business sector. The results also indicated that there was no difference in mean scores between the groups being compared.

Instrument Development

Before conducting the instrument development, the research constructs were conceptualized to specify the domains associated with e-commerce activities. Based on the result of the existing relevant literature review discussed in the previous section, conceptual definitions of constructs are developed and shown in Table 4.

Table 4. Definition/ description of latent variables

Variables	Definitions/Description	References
Perceived government supports (GovS)	Represents the things reflect the role of government and its institutions, in orienting, supporting, regulating and managing, and monitoring e-commerce environment. It includes four facets: strategic directive role (having visions or macro plans and commitment), practical directive role (having e-Government initiates), management role to stop or eliminate risks in e-transaction (having legal documents, regulations), and supporting role (having supporting policies regarded to human, finance, and technique.)	Molla & Licker (2005), Ruikar et al. (2006), Saprikis (2013)
Perceived legal and regulations system (PLR)	Represents legal requirements and regulations to stop or eliminate risks in e-business transactions; so as to ensure the security of e-commerce activities and improve trust in e-transactions.	Kog (2010); Ismail & Kamat (2006); APEC (2006)
Perceived market forces (MFS)	It refers to the assessment that the pressure from business competitors and supports from partners (such as customers and suppliers) in conducting e-business.	Molla & Licker (2005); Burns & Burns (2008)
Social awareness of e-commerce (SW)	Represents issues related to social culture, knowledge, and attitudes of a community towards e-commerce. It has four facets: (1) industrial economic characteristics (competitiveness, transparency, stableness; trend of collaboration and cooperation), (2) industrial socio-culture characteristics (trust, beliefs, concepts, judgments, expectations, and methodologies towards e-commerce) that are shared by people and enterprises within the industry. (3) They are also industrial knowledge characteristics (perception of e-commerce, skilled labor force, technicians, IT-oriented managers) that required for the development of e-commerce strategy, and (4) industrial knowledge sharing supporting infrastructure (all initiatives, actions, and plans available that develop knowledge and positive culture for e-commerce).	Ismail & Kamat (2008); Zhu et al. (2006); Huang (2009)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Development of the instrument followed the guidelines present by Moore & Benbasat (1991). Accordingly, this process includes three stages. The first stage was item creation. Its purpose was to create pools of items for each variable by identifying items from existing scales, and by creating additional items, that appeared to fit the construct definitions. The second stage was scale development. The basic procedure was to have panels of judge sort the items from the first stage into separate categories, based on the similarities and differences among items. Then the items was examined and dropped if any inappropriate wording or ambiguousness. The third stage was to test the overall instrument with the various scales developed previously. This stage includes three separate steps. First, the instrument was distributed to a small sample of respondents and then an analysis of the responses was carried out to get an initial indication of the scales' reliability. Items which did not contribute to the reliability were dropped from a full pilot test with a larger number of subjects. In the third step, the scales were further refined, and a field test of the instrument was conducted. The final questionnaire was shown in Appendices A.

DATA ANALYSIS

The research hypotheses were tested using structural equation modeling (SEM) implementing partial least squares (PLS) technique.

Assessment of Measurement Model

Prior to data analysis, three measurement properties need to be examined to ensure that the model has a satisfactory level of reliability and validity. To evaluate individual item reliability, the standardized loadings (or simple correlation) were assessed. A rule of thumb employed by many researchers is to accept items with loadings of 0.7 or more, which implies that there is more shared variance between the latent variables and its measure than error variance. Based on the output of confirmatory factor analysis (CFA) from Smart-PLS 2.0 M3, all items have loadings above 0.70. In addition, the loadings are all statistically significant. Therefore, it can be said that all the items demonstrate satisfactory level of individual item reliability.

Second, convergent validity was also examined by evaluating Cronbach's alpha by SPSS 19.0. This is to measure the internal consistency. It is estimated to ensure that the items assumed to measure each

Table 5. AVE and Cronbach's Alpha

Reflective Constructs	AVE	Cronbach's Alpha
GovS	0.7170	0.7882
MFS	0.6675	0.8864
PLR	0.6293	0.7961
SW	0.6192	0.8562
eCIA	0.6634	0.8715
eCI	0.7030	0.7040
Benchmark	0.5	0.6

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

latent variable measures them and not measuring another latent variable. The Cronbach's alpha obtained for each construct is listed in Table 5. All constructs have acceptable convergent validity, as a value of 0.70 is usually accepted as the minimum desired value of the Cronbach's alpha.

Third, the discriminant validity of the measurement scale was tested. The analysis of cross-loading was carried out by following the rule that items should have a higher correlation with the latent variable that they are supposed to measure than with any other latent variable in the model (Chin, 1998). First, SmartPLS 2.0 M3 was used to generate the latent variable scores for all the six reflective variables and

Table 6. The cross loadings of constructs

Items	GovS	MFS	LRS	SW	eCI	eCIA

eCIA2	0.84	0.70	0.83	0.60	0.90	**0.98**

Legend: The highest Pearson Correlation coefficient is highlighted

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

standardized scores for each measurement item. Next, these scores were then entered into SPSS 19.0 to calculate Pearson's correlation coefficients for all the items. The Pearson correlation results are present in Table 6. The results showed that all items loaded higher on the latent variable they were theoretically specified to measure than any other latent variable in the model (see the highlighted correlation coefficients). In other words, the analysis demonstrated discriminant validity of the six latent variables.

In PLS, analysis of average variance extracted (AVE) is also useful for assessing the adequacy of discriminant validity at construct level. Accordingly, a latent variable should share more variance with its measures than it shares with other latent variables. AVE of a latent factor should be greater than the variance shared between the latent factor and other latent factor (e.g. the squared between two latent factor). The rule is that the square root of AVE of each latent variable should be larger than the correlation of two latent variables. Here, the correlation matrix for the latent factors was established (see Table 7). The results show that there was no correlation between any two latent variables larger than or even equal to the square root AVEs of the two latent variables. Thus, the analysis demonstrated discriminant validity. Therefore, having satisfied the three measurement properties, it can be concluded that the constructs are measured with adequate precision.

Table 7. The correlation of constructs and the square root of AVE

Items	GovS	MFS	PLR	SW	eCI	eCIA
GovS	**0.847**					
MFS	0.134	**0.817**

Assessment of Structural Model

Table 8 contains a summary of the hypotheses, the path coefficients obtained from the PLS analysis, the t-values, and associated levels of significance for each path.

Test of Predictive Validity of the Structural Model

The explanatory power of the model was assessed by examining the amount of variance in the dependent variable that can be explained by the model. Smart-PLS 2.0 3M provided the squared multi correlations (R2) for two dependent variables in a model. In this study, the R2 for "e-commerce initial adoption" and "e-commerce institutionalization" are 0.50 and 0.45 respectively meaning that about 50% and 45% of the changes in the entry-level adoption and institutionalization of e-commerce in SMEs is due to the four institutional variables in the model. Now, it can be summarized that the modified model and its instrument are sufficiently valid to explain adoption and institutionalization of e-commerce in SMEs.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Test of Research Hypotheses

Each hypothesis was tested by looking at the sign, size, and statistical significance of the path coefficient between the independent and dependent variable. The bootstrap function in Smart-PLS 2.0 3M was used with 200 re-samples. Five of the eight paths are statistically significant (see Table 8). For e-commerce initial adoption (eCIA), two of the four institutional factors – GovS and PLR – have significant paths. For institutionalization of e-commerce (eCI), three of the four institutional factors –SW, PLRS, and MFS – have significant paths.

Table 8. Path coefficients and t values

Path	Expected Sign	Path Coefficients	t-Values	Inference
Dependent construct: E-commerce Initial Adoption (eCIA)				
H1a: GovS->eCIA	+	0.13	1.75*	Supported
H5a: LRS ->eCIA	+	0.16	1.99*	Supported
Dependent construct: Intention for E-commerce Institutionalization (eCI)				
H5b: LRS ->eCI	+	0.43	3.73**	Supported
H3b: SW ->eCI	+	0.34	4.21**	Supported
H2b: MFS ->eCI	+	0.21	2.53**	Supported

Legend: **=highly significant, *=significant; critical t-value: 1.96 p<0.05 and 2.58 p<0.01

The 2016 Follow-Up Interview Data Analysis

The qualitative data is collected in the face-to-face manner with four specific participants in September 2016. The analysis and results of those qualitative interviews helped the researcher clarifies the participants' responses in the full survey and complemented the previous quantitative analyses and results. The following report on the qualitative interviews was present in descriptive narrative and succinct form, categorized into five headings corresponding to two dependent variables and four independent variables in the quantitative results, and supported by interview participants' quotations (in italics in the following texts). This approach of analyzing the interview data was suited to the relatively small number of interviews in this study and the purpose of cross validating the effects of four institutionally influential factors for e-commerce adoption.

The first company was coded as SME1. According to its website, SME1 was a sport equipment manufacturing company. It had more than 150 employees. Its key customers included schools, sport centers, and organizations. Its strategic partners included local small and large enterprises. Its products and services included sport equipment of which the prices range from US$5 to over 10,000. In previous years, SEM1 average R&D investment was around US$ 30,000. The interviewee was a process improvement manager at the company, focusing on strategic business planning and organizational development. He had over 25 years of experience ranging from an officer to a member of senior management.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The second company was coded as SME2. It was a local branch of a China-based Zhongfong manufacturing company. Its major products were pet foods. It had over 100 employees. Its primary customers were farms. The interviewee had worked for three years in a position for procurement management and had recently served as a member of a regional business management team.

The last company was coded as SME3. It was an advertising agency company focusing on online advertising and public relations, interactive marketing, and media resource planning and purchasing. Its primary customers were online gaming vendors and operators. SME3 was a small company with about 50 employees in Riyadh. The interviewee was a director of technology for five years ago. The results are discussed in detail in the following sub-sections.

Initial Adoption of E-Commerce and Intention for E-Commerce Institutionalization

With regard to the sophistication and usage level of B2B e-commerce adoption, SME1 was still in the stage of "initial adoption" in 2016, meanwhile SME2 and SME3 were at the more sophisticated e-commerce level.

As for SME1, its major B2B partners were retailing vendors. Its business transactions with those external vendors had involved B2B e-commerce at the simple level since 2010 and continue to now. Two examples given are that the enterprise started to use e-mail since 2010, and established a static website since 2011, respectively. Then it improved their websites to the interactive websites years later to make promotions and publish basic company information or receive queries, e-mail, and form entry from users. At presently, a quite much part of electronic fund transfer has been conducting electronically through e-banking systems. However, the company does not have an online CRM or SCM systems. The interviewee from SME1 also confirmed that back in 2013; her company "had no organized or systematic operations of electronic purchasing." She also admitted that SME1 was not early adopters of e-commerce because of the concern of return-of investment of new technology and IT infrastructure barriers. And that SME1 does not have any plan to invest and improve its initial e-commerce status in near future. The interviewee also said that SME1's "IT infrastructure is not strong enough," and its overall intention level of e-commerce institutionalization was "at very low level." These are consistent with the 2013 full survey. The scores of initial B2B e-commerce adoption (eCIA) and of intention for e-commerce institutionalization (eCI) of SME1in the 2013 full survey were 3.7and 2.2 out of 5, respectively.

As for SME2, at present this company is at the middle institutionalization level of e-commerce. In the 2016 interview, the interviewee told that SME2 invested and retrofitted the initial e-commerce status to become a more sophisticated e-commerce system in 2015. Especially, the new system of e-commerce is integrated with e-marketplace and aligned with the company's new business strategy. In early 2016, SME2 "began to adopt e-commerce based on a third-party purchasing platform provided by Ariba." Since then, all long operations of SME2's purchasing had been through this platform. With the close cooperation with Chinese, SME2 had adopted B2B e-commerce extensively in its supply chain. Integrating its purchasing platform with its internal ERP system provided by SAP, SME2 was able to place orders with its suppliers online and its suppliers were able to take the orders on a real-time basis. SEM2 also used EDI to share information internally with its parent company in the U.S. and peer companies in Europe. However, it was still at a low level in SME2 with respect to electronic data interchange of order and sales with external business partners, including suppliers and customers. The "intention for B2B e-commerce institutionalization (eCI)" items for SME2 have been received high scores in the 2013 full survey, and the overall score of eCI was 4.0 out of 5.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

As an online advertising company with about ten years old, SME3 is presently at the high level of e-commerce institutionalization. It "has been using e-commerce more and more frequently because the overall e-commerce development in Saudi Arabia has become more and more mature, especially in IT sector." The eCIA and eCI scores of SME3 based on the 2013 full survey were 2.18 and 4.1 out of 5. As a newly founded online business solution provider itself, SME3 had the highest score of eCI among three interviewed companies in 2013. Its response in the 2016 interview survey showed that SME3 had been using or at least intended to use most of the e-commerce technologies listed in the survey, except for receiving customer orders on the company's website. The company normally assigned specific a sales and customer service representative to each customer. Although the customers themselves were unable to place orders over the Internet directly, the company's representatives could place orders for the customers over the company's intranet. In the near future, SME3 planned to develop and implement an e-business system that would integrate better with its customers. It hoped to "involve more in e-commerce and expand its usage." It had a strong customer-oriented application of web-based e-commerce technologies, such as a multi-functional website, EDI system and CRM system. SME3's interviewee specified the sales model of the company—SAS (software and service), which treated the product of software as a kind of service and offered this service online, with the abilities to provide technical support and customer communication and deliver software upgrades all online.

Ranking Institutional Factors

All interviewees were asked to rank the institutional factors' effects on their decision of B2B e-commerce adoption. For a decision of initial adoption of e-commerce, "government support" and "legal and regulations" received the highest rank across all interviewees; and "market forces" and "social awareness" factors in order. For a decision of e-commerce institutionalization, the "social awareness", "legal and regulations", and "market forces" received the highest rank across all interviewees, and the "government supports" factor in order.

In addition, regarding SME2 that was at the initial level of e-commerce adoption in 2013, GovS and PLR were the two institutional factors only influencing on their decision of e-commerce adoption. For 2016 as SME2 has an intention for at the more sophisticated level of e-commerce adoption, MFS, PLR, and PSW were in the three top in order predicting its e-commerce adoption. Regarding SME3, when it was at the initial level of e-commerce in 2013, GovS and PLR were also the two institutional determinants of their decision of e-commerce adoption only. In 2016 as SME3 is already at the institutionalization of e-commerce, MFS, PSW, and PLR were in the three top in order predicting its decision of e-commerce. Regarding SME1 that did not change its adoption level between 2013 and 2016, and rankings of the institutional factors also did not change.

Thus, it can be said that there is a clear change in terms of institutionally influential factors of e-commerce adoption over time in each enterprise as the level of e-commerce adoption changes. This result is consistent with the quantitative data analysis that indicated that predictors differ for initial e-commerce adoption and intention for e-commerce institutionalization.

DISCUSSION

Data analysis showed that GovS had significant influence a decision of initial adoption of e-commerce but did not have any impact on intention for e-commerce institutionalization in Saudi SMEs. This finding is completely consistent with the result reported by Leung et al. (2005) and the conventional wisdom that emphasizes the influence of the macro-environment on entry-level e-commerce adoption (Molla & Licker, 2005).

For the reason of this finding, in developing countries, competitive environment is often determined by the relationship between businesses and government, and additionally, business managers in SMEs often trend to be oriented by government's directions and less willing to accept changes (Huang et al., 2014). Furthermore, in the Kingdom of Saudi Arabia, at presently, there is an absence of government responsibility for e-commerce as well as no long and short -term strategic plans for the e-commerce environment development. Saudi people tend to feel more confident in business ventures if they are backed by the Government. Therefore, SMEs in the KSA more likely move to e-commerce at the entry-level if they receive enough government's supports in terms of regulation, laws, financing, and technical issues, however a decision of e-commerce maturity and sophistication in Saudi SMEs may depend much more on other factors; for example, managers' commitment, and resources.

Perceived legal and regulations support is the most significant institutional determinant of both the entry-level adoption and institutionalization of e-commerce in Saudi SMEs. This result is consistent with previous empirical findings (Molla & Licker, 2005). Our finding gives empirical support to qualitative research that identifies many legal obstacles to e-commerce, such as inadequate legal protection for online transactions, unclear business laws, and security and privacy concerns (Ismail & Kamat, 2006; Kog, 2010). By implication, this result points to the need for establishing a broad legal and institutional framework that makes a trustworthy e-marketplace.

Perceived market forces were found to have significant effects on only intention for e-commerce institutionalization in Saudi SMEs. This finding is completely consistent with the results reported by Molla & Licker (2005). It is also supported by (Tran et al., 2014) when they found that external business characteristics were critical factors affecting the institutionalization of e-procurement in construction industry in Vietnam. They confirmed the importance of meso-level environmental factor in e-commerce adoption, as market forces tend to be relatively specific to a given sector and industry. In fact, in the KSA, enterprises consider consumer purchasing power to be weak and not support them to run e-commerce. They are just waiting to see how the e-marketplace develops. This result indicates that the extent to which e-commerce is used by different business partners can motivate SMEs toward more sophisticated e-commerce implementation because of perceived benefit values or fear of market displacement or forces from partners towards supply chain integration.

Perceived social awareness of e-commerce was found to have significant impact on institutionalization but not on a decision of initial adoption of e-commerce in SMEs. The result is supported by empirical findings in other developing countries (Tran et al., 2014). This implies that information sharing culture, positive perception of the role of information, and positive attitudes toward IT and e-commerce by people will be critical for SMEs in implementing sophisticatedly e-commerce (Teo et al., 2009). Such characteristics are all the more important in developing countries, such as KSA, where information sharing is facing the "rigidity" of public administration and even private businesses.

CONCLUSION

The analysis result in 2013 and 2016 demonstrated that there is a clear difference between initial e-commerce adoption and intention for e-commerce institutionalization in SMEs in terms of institutional predictors. Supports of government and perceived legal and regulations supports are more critical in pulling SMEs towards a decision of initial e-commerce adoption rather than intention for e-commerce institutionalization. When e-commerce adoption was at its infant stage, supports from governmental initiatives and legal systems were instrumental and served as initial institutional forces to encourage firms to adopt e-commerce. Meanwhile, perceived industrial pressures (i.e. market forces), and perceived social awareness pushed initial adopters to engage in e-commerce more sophisticatedly. As time went on, the effect of government supports become insignificant but these factors remained relatively stable.

This study extended the institutional theory by adding a new research lens—time. Employing such a temporal lens provides a new and powerful way to investigate and better understand the contextual factors for e-commerce adoption at different stages in SMEs. The study has following limitations, such as limited generalizability for the other regions in Middle East, not diversified data in terms of geographical regions, and small sample size. Additionally, the research instrument should be tested for test–retest reliability and external validity. Replicating the study would enable such tests. Some respondents suggested that the issues addressed in our study should be conducted in specific industries because different industries may have different considerations in their adoption of e-commerce due to various institutional pressures. Finally, moderating factors should be taken into consideration while analyzing institutional relationships on e-commerce adoption.

Chapter 19
An Analysis of the Factors Influencing the Adoption of Online Shopping

ABSTRACT

This article aims to identify the main influencing factors that may influence the adoption of online shopping in the UK by integrating Unified Theory of Acceptance and Use of Technology2 (UTAUT2) and DeLone-McLean model of IS Success with trust (TR), product variety (PRDV) and product guarantee. Data was collected from 388 British online shopping consumers using a structured self-administrated questionnaire. Structural equation modeling (SEM) showed that behavioural intention (BI) was influenced by performance expectancy (PE), convenience (CON), service quality (SerQ), trust (TR), product guarantee (PG), product guarantee (PRDV) and compatibility (COMP), in their order of influencing strength and all together accounted for 70.4% of the variance in BI. Contrary to the authors' expectations, effort expectancy (EE) and social influence (SI) did not have an influence on BI. The implications of this article to both theory and practice is discussed at the end.

INTRODUCTION

The rapid growth of the Internet retailers during the past two decades has undoubtedly quelled the overly optimistic expectations for on-line business to consumer (B2C) commerce (Zolait & Sulaiman, 2008; Celik, 2016). Most of the customers have recognized the importance of online shopping in their everyday lives, such as overcoming time and spatial barriers, convenience, competitive pricing, expert advice, customized service and greater access to information (Lim, 2015). However, many customers are still reluctant to shop online due to poor online customer experience (Lin, 2008). A related and arguably a more pressing problem for Internet retailers is identifying, attracting, and keeping customers (Chang et al., 2015; Tarhini et al., 2016).

The United Kingdom had the largest electronic commerce market in Europe in 2014 and accounted for 32% (roughly 118 billion Euro) of European e-commerce sales (Statista, 2015). However, many of the UK internet users still reluctant to use online shopping services (Turner & Callaghan, 2006; Ramanathan, 2011; Celik, 2016). Furthermore, the UK losses 19 billion Euro yearly of the annual online revenue due to poor online customer experience (Statista, 2015). Hence, it becomes vital for marketers and policy makers to have a deeper understanding of their customers to formulate strategies to enhance their experience (Zhou et al., 2007; Jeong et al., 2009; Lim, 2015). In order to have a better understanding of customers, both academics and online marketers must understand the factors that may hinder or enable the acceptance of online shopping.

Although there are many studies that examine the antecedents of online shopping (e.g. Çelik & Yilmaz, 2011; Clemes, Gan & Zhang, 2014; Chang et al., 2015; Amaro & Duarte, 2015; Celik, 2016), many researchers acknowledge that there still a gap in the understanding of online shopping (Dennis et al., 2009; Hand et al., 2009; Hansen & Jensen, 2009; Lim & Ting, 2012; Lim, 2015) and called for future studies that examine the influencing factors of online shopping.

Various models and theories have been mainly developed and employed to examine and predict the adoption of technology such as Technology Acceptance Model (TAM); Theory of Reasoned Action (TRA); Theory of Planned Behaviour (TPB); Innovation Diffusion Theory (IDT); Model of PC Utilization (MPCU); Motivation Model (MM), Social Cognitive Theory (SCT), Unified Theory of Acceptance and Use of Technology (UTAUT) and the Information Systems Success Model (IS Success Model). Hence, taking into consideration the importance of integrating both the Unified Theory of acceptance and Use Technology (UTAUT2, Venkatesh et al., 2012) and the Information Systems Success Model (IS Success Model, Delone & Mclean, 2004), and to answer the call of previous research (Delone & Mclean, 2004; Venkatesh et al., 2012) on this area to extend the extant models, this paper aims to propose a model which could be able to explain, theoretically and empirically, the main factors that may hinder or enable the adoption of online shopping by British customers. This study will enable the marketers to formulate strategies aiming at improving the take up of online shopping. Furthermore, only integrating the constructs from the two models may not necessarily portrays a complete picture of the phenomena under investigation. Therefore, trust, product guarantee and product variety were integrated into our model in order to have a better understanding of consumer adoption of online shopping. Indeed, these 3 factors appears to be a key predictor that made the customers use the online shopping services (Dennis et al., 2010; Clemes et al. 2014; Chen et al., 2015; Amaro & Duarte, 2015; Chang et al., 2015; Lim et al., 2016). Therefore, adding these factors will complement the existing factors of the UTAUT2 and IS Success Model and are expected to have a direct influence on behavioural intention towards using online shopping services. From the theoretical perspective, there are scare studies that integrate UTAUT2 and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

IS Success Model and to the best of the authors' knowledge, there are no previous studies that integrate these two models together with the 3 added factors. Therefore, this paper contributes to the literature related to theories and models of technology adoption and acceptance and this is considered a critical step to advance a theory (Johns, 2006; Alvesson & Kärreman, 2007).

THEORETICAL FRAMEWORK

The Unified Theory of Acceptance and Use of Technology (UTAUT) theorised by Venkatesh et al. (2003) was adopted as theoretical base of the current conceptual model. In fact, the most significant factors from the eight theories and models (Theory of Reasoned Action, Theory of Planned Behaviour, Technology Acceptance Model, Motivational Model, Combined of Technology Acceptance Model and Theory of Planned Behaviour, Model of PC Utilisation, Social Cognitive Theory, and Innovation Diffusion Theory) were examined, compared, synthesised and integrated by Venkatesh et al. (2003) in one unified model named UTAUT. In the UTAUT, Venkatesh et al. (2003) identified three constructs as key determinants of the behavioural intention to use technology. These constructs are performance expectancy, effort expectancy, and social influences. Facilitating conditions and behavioural intention both were also proposed to have a direct influence on the actual use behaviour (Venkatesh et al., 2003). Indeed, Venkatesh's et al. (2003) model has been broadly considered to be a one of the most inclusiveness and parsimonious models to explain technology usage (Bagozzi, 2007). Further, about 70 percent of the variance in behavioural intention was account for by UTAUT which has never been recorded by any other model (Alalwan et al., 2014; Venkatesh et al., 2003).

Over the prior literature of information system and technology acceptance, the UTAUT has been extensively adopted to examine the individuals' intention and behaviour toward different kinds of technologies such as Internet banking (i.e. Abu-Shanab et al. 2010; Tarhini et al., 2015); Mobile banking (i.e. Zhou et al., 2010); E-learning (i.e. Van Raaij & Schepers, 2008); E-government (i.e. Qasem & Zolait, 2014; Rana et al., 2015); online shopping (Yang, 2009). Further evidence supporting the validity of UTAUT has been introduced by Dwivedi et al. (2011) based on their meta-analyses of 43 articles that have partially or fully adopted the UTAUT. Dwivedi et al. (2011) revealed that the most influential factor predicting behavioural intention among UTAUT constructs is performance expectancy. Also, social influences, effort expectancy, and facilitating conditions (listed in order of their influence) are all key drivers of behavioural intention. In addition, Dwivedi et al. (2011) confirmed a high reliability degree (over 0.70) for each factor in the UTAUT model.

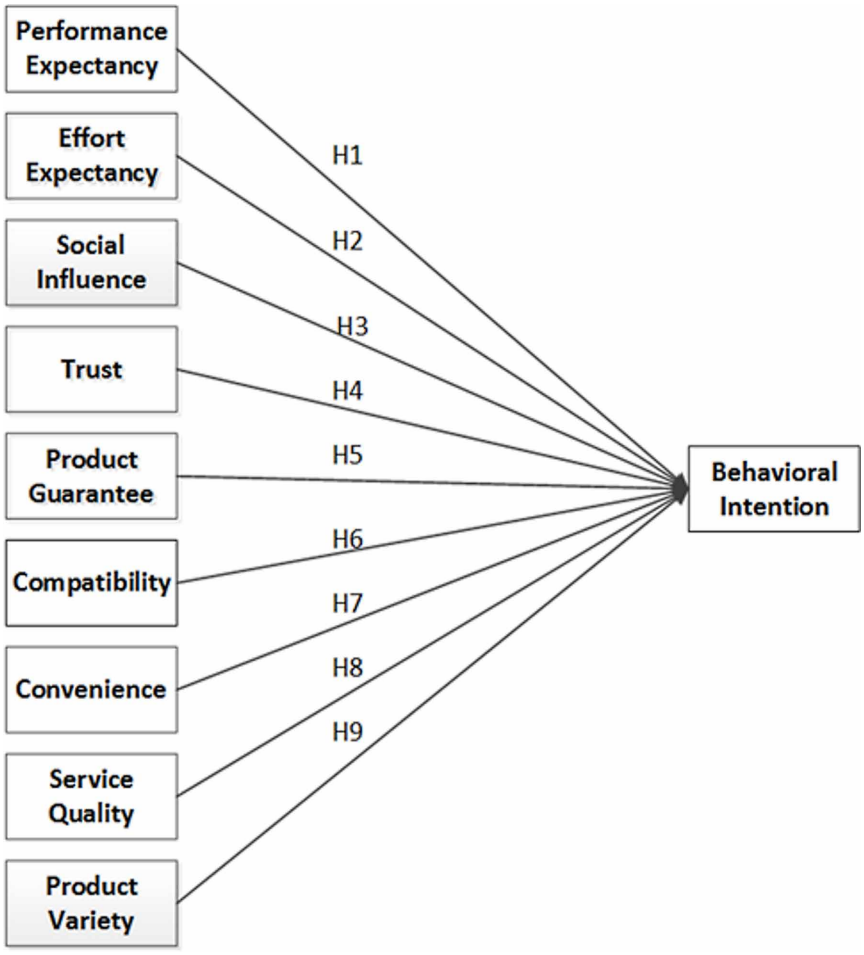
In the light of the above discussion, and as, this study primarily aims to formulate a better understanding toward the adoption of online shopping and discovering the main factors predicting customers' decision to use or reject such system to use or reject such. In the line with this aim, the proposed conceptual model should cover the most important aspects taken into account by customers in this regard. Yet, as this study fully concentrates on the behavioural intention, three factors (performance expectancy, effort expectancy, and social influences) were only extracted from UTAUT in the current conceptual model while facilitating conditions was excluded. However, an analysis of the prior literature of online shopping leads to observe that there are other important factors are not presented in the UTAUT. Among of these factors is trust which has been validated and proven by many studies such as Ha and Stoel (2009); Hong and Cha (2013); Gao et al. (2015); Chiu et al. (2012); Rauniar et al. (2014); Amaro and Duarte (2015); and Chang et al. (2015). Perceived enjoyment has been also confirmed to be crucial factor predicting

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

customer's intention to adopt online shopping (i.e. Ingham et al., 2015; Kim & Niehm, 2008). Another important factor was compatibility that has been approved by number of studies as well (i.e. Vijayasarathy, 2004; Amaro & Duarte, 2015). Product guarantee and product variety have derived attention by several researchers in the online shopping field (Amaro & Duarte, 2015; Jensen, 2009; Clemes et al., 2014; Koyuncu & Bhattacharya, 2004). Different online shopping researchers (i.e. Amaro & Duarte, 2015; Mayr & Zins, 2009; Gao et al., 2015; Chen et al., 2015) have paid interest to the role of convenience in shaping customers intention. Finally, service quality has been proposed and supported by good number of researchers of the related area of online shopping (i.e. Gao et al., 2015; Lin & Wang, 2006; Zhou, 2014; Zhou et al., 2013; Lee & Chung, 2009; Zhou, 2011; Shamala et al., 2017).

Accordingly, all of these seven factors: trust, enjoyment, compatibility, product guarantee, product variety, convenience, and service quality are proposed in conjunction with UTAUT factors: performance expectancy, effort expectancy, and social influence as key predictors of the customers' intention to adopt online shopping (see Figure 1). More explanation and justifications of the conceptual model and research hypotheses are presented in the forthcoming subsections.

Figure 1. The Proposed Conceptual Model



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Performance Expectancy

According to Venkatesh et al. (2003), performance expectancy pertains to the extent of how much people perceive a new technology is useful their daily life in terms of having more productivity as well as saving their time and efforts. In validating UTAUT, five constructs [(perceived usefulness (Davis et al., 1989); outcome expectation (Bandura, 1986); extrinsic motivation (Davis et al., 1992); relative advantage (Rogers, 2003), and job fit (Thompson et al. (1991)] capture the role of performance expectancy (Venkatesh et al., 2003). Indeed, either performance expectancy or its similar constructs represent the cognitive benefits perceived in using a new technology (Dwivedi et al., 2011; Rana et al., 2013; Amaro & Duarte, 2015; Tarhini et al., 2015). Importantly, such sort of benefits has been largely noticed to be able to keep their significant influence on the individuals' perception and willingness to adopt different kind of applications (Zhou et al., 2010; Alalwan et al., 2014; Rana et al., 2015). Customers' intention to use online shopping was also found out to be strongly predicted by the role of perceived usefulness as similar construct to performance expectancy (see Lin, 2007; Mandilas et al., 2013; Chong et al., 2012; Ingham et al., 2015; Agrebi & Jallais, 2015; Vijayasarathy, 2004; Rauniar et al., 2013). Further, performance expectancy was proven by Pascual-Miguel et al. (2015) to have a positive significant impact on the behavioural intention to adopt online shopping by both genders. Accordingly, it could be concluded that as long as customers perceive online shopping is more useful in their life, they will be more motivated to adopt it. Thus, the following hypothesis proposed is:

H1: Performance expectancy will positively influence customers' intention to adopt online shopping.

Effort Expectancy

Effort expectancy was identified as the "extent of ease connected with the use of system" (Venkatesh et al., 2003, p.450). Three constructs: perceived ease of use (Davis et al., 1989); complexity (Rogers, 2003); and ease of use (Moore & Benbasat, 1991) were formulated under the concept of effort expectancy in the UTAUT (Venkatesh et al., 2003). Although the usefulness perceived in adopting a new system represents important aspects considered by individuals, the extent of how much such system is simple and easy to use still derives a considerable attention from individuals in this regard (Davis et al., 1989; Venkatesh & Davis, 2000). Further, in the light of the fact that using online shopping requires customers to conduct the purchasing process alone and without any assistance from firms' staff, customers need to enjoy with a certain level of knowledge and skill (Alalwan et al., 2015). Therefore, effort expectancy is supposed to have a considerable impact on the customers' intention to adopt online shopping. This supposition has been supported by Lin (2007) and Ingham et al. (2015) who empirically noticed a significant association between perceived ease of use (as similar factor to effort expectancy) and customer's attitudes toward online shopping. More recently, Pascual-Miguel et al. (2015) approved that female's intention to use online shopping is largely predicted by the role of effort expectancy, yet such relationship is more likely to vanish for male groups. Mandilas et al. (2013) also confirmed a significant direct relationship between perceived ease of use with customer intention to use online shopping. All things considered, this study proposes the following hypothesis:

H2: Effort expectancy will positively influence customers' intention to adopt online shopping.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Social Influence

Venkatesh et al. (2003, p.450) defined social influence as "the extent to which an individual perceives that important others believe he or she should apply the new system". Conceptually, social influence captures the role of subjective norms, social factors, and image as proposed by Venkatesh et al. (2003) in the UTAUT. As for customer online shopping behaviour, social influence could be addressed under the impact of people (i.e. family, friends, and colleagues) whom customer could ask for either information or social approval to use online shopping (i.e. Lin, 2007; Chong et al., 2012; Algharabat, 2014; Alqasa et al., 2014; Pascual-Miguel et al., 2015; Clemes et al., 2014; Ingham et al., 2015). The impact of social influence on the customer intention to use online shopping has been approved by number of online shopping studies. For instance, Chong et al. (2012) demonstrated that Malaysian consumer's decision was found out to be statistically predicted by the role of social influence. Similar factor to social influence, subjective norms has been also confirmed to have a significant impact on the customers' adoption of online shopping as stated by Clemes et al. (2014). In their meta-analytic review, Ingham et al. (2015) supported that social influence has been able to maintain its significant influence on customers' intention over the most studies that have examined the customers' adoption of online shopping. Thus, the following hypothesis supposes that:

H3: Social influence will have a positive impact on customers' intention to adopt online shopping.

Trust

According to Gefen et al. (2003), trust is more related to the individuals' beliefs that the targeted website has sufficient level of ability, benevolence, and integrity. Arguably, trust has been largely discussed over the prior literature as mechanism adopted by individuals to mitigate the concerns expected in using a new system (i.e. Chen et al., 2015; Hong & Cha, 2013; Ha & Stoel, 2009; Gao et al., 2015; Chiu et al., 2012; Rauniar et al., 2014; Amaro & Duarte, 2015; Chang et al., 2015). Further, using online shopping are most likely to comprise a such kind of financial transaction which could make customers perceive further risk is using these systems (Hong & Cha, 2013). This is in addition to the fact that there is not any kind of human interaction over the online shopping platforms, and accordingly, comprising more uncertainty and vagueness in the results of using online shopping (Algarabat & Zamil, 2013; Chen et al., 2015; Ingham et al., 2015). Thus, it could be concluded that customers are more likely to be less motivated to use online shopping, if they do not fully trust in using such systems. Indeed, several studies that have acknowledged the significant impact of trust on the customer's intention to use online shopping. Such of that, Chiu et al. (2012) established that customers' repeat purchase intention to use online stores is strongly contributed by the role of trust. Another strong relationship between trust and customer' willingness to use online shopping was approved by Hong and Cha (2013). These results have been recently supported by Ingham et al. (2015) who provided more evidences confirming the role of trust on the customers' intention to use online shopping. Therefore, this study suggests the following hypothesis:

H4: Trust will have a positive impact on customers' intention to adopt online shopping.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Product Guarantee

Customer could not be sure about the results of using online shopping and that products purchased online matches the quality standards identified in the website (Koyuncu & Bhattacharya, 2004). Indeed, using online shopping comprises face to screen interaction, and accordingly, customers are only able to see the targeted products via the screen of computer and mobile phone (Robertson & Shaw, 2009). This is unlike traditional brick and mortar stores where customers can physically look at product prior taking his or her purchasing decision. Further important, customers seem to be more careful and concerns if the targeted products are highly expensive and comprise an extent degree of risk (Koyuncu & Bhattacharya, 2004). Customers are more likely to refuse purchasing these products from the online stores if the firm does not assure him or her that these products are reliable and trustworthy (Koyuncu & Bhattacharya, 2004). According to Clemes et al. (2014) and Koyuncu and Bhattacharya (2004), firms could be more able to mitigate customers concerns and motivating them to use online shopping by using an effective product guarantee police. In this regard, return police was statistically proven by Yingjiao and Paulins (2005) to be a significant factor contributing the customer's adoption of online shopping. Thus, the following hypothesis proposes that:

H5: Product guarantee will have a positive impact on customers' intention to adopt online shopping.

Compatibility

Compatibility is viewed as "the degree to which an innovation is perceived as being consistent with the existing value, past experiences and needs to potential adopters" (Rogers, 2003, p.240). Indeed, as long as customer perceives using online shopping compatible with other systems used by them (i.e. Internet, social media, online banking), compatible with their values and requirements as well, they will express less resistance to use such system and being more interest to adopt it (Vijayasarathy, 2004). The important role of compatibility on the customer's attitudes, intention and behaviour toward new systems has been largely confirmed (Alalwan et al., 2014; Chen & Huang, 2006). As for online shopping, Vijayasarathy (2004) found that customers, who perceive using online shopping is compatible with their life style, need, and values, are more likely to be formulate positive attitudes toward such system. In the line with these results, Lin (2007) established that compatibility has a significant impact on the customers' intention to sue online shopping by mediating role of attitudes. More recently, Amaro and Duarte (2015) empirically confirmed the impacting role of compatibility on the customer's intention to use online shopping. Therefore, the following hypothesis proposes that:

H6: Compatibility will have a positive impact on customers' intention to adopt online shopping.

Convenience

By using the online shopping, customers will be allowed to access a wide range of products, services, and information 24 a day and 7 days a week at any place of the customers' selection (Clemes et al., 2014). Indeed, by removing the time and place restrictions, customers will be more able to do their shopping simpler, easier and faster (Soopramanien & Robertson, 2007; Prasad & Aryasri, 2009). This, in turn, makes customers more motivated to adopt online shopping as stated by Kim et al. (2009); Mee and Huei

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

(2015) and Chen (2015). In the line with this, Prasad and Aryasri (2009) demonstrated that customer's penchant to adopt online shopping will reach a high level among those customers who perceive online shopping as more convenient way to do their purchasing process. Convenience was also considered by Schaupp and Belanger (2005) as a one of the main factor predicting the customers experience with online shopping. Accordingly, the following hypothesis proposes that:

H7: Convenience will have a positive impact on customers' intention to adopt online shopping.

Service Quality

According to DeLone and McLean (1992) and Parasuraman et al., 1988 Service quality could be defined as the degree to which customer perceives a system as reliable, empathetic, secure, and creditable (DeLone and McLean, 1992; Shamala, *et al.,* 2017). Both personalisation and interactivity are also other important aspects of service quality that have to exist in any online shopping website to accelerate the customers' online shopping experience (DeLone & McLean, 2004). Service quality plays an important role in contributing the customer trust in the website (Gao et al. 2015). Thus, customers are more likely to be motivated to adopt online shopping if the perceive a high degree of service quality existing in the targeted website. This proposition was early supported by Liao et al. (2010) who indicted that service quality has a statistical significant impact on the customers' willingness to adopt online shopping. By the same token, a positive strong association was noticed by Vijayasarathy and Jones (2000) between service quality and customers' intention to adopt online shopping. As said by Yang and Jun, (2002), security represents the main issues that could hinder or contribute to the non-users' intention to adopt online shopping instead of the reliability aspects which were of the focus of attention of the actual users of online shopping. Further, Lee and Lin (2005) empirically supported a strong positive relationship between service quality and customers' penchant to adopt online shopping. Therefore, the following hypothesis propositions:

H8: Service quality will have a positive impact on the customer's intention to adopt online shopping.

Product Variety

Hansen and Jensen (2009) asserted the importance of accelerating customer online shopping experience by providing a broad range of products and services that customers can select among them. Thus, product variety was noticed as one of the key motives of the customers adoption of online shopping as stated by Szymanski and Hise (2000). According to Van Herpen and Pieters (2002), the way to present the targeted products by firms, product attributes, and repetition frequency, and number of products presented all are key factors predicting the way that customer perceive the aspects related to variety. Cho (2004) confirmed a positive significant relationship between product variety and adoption of online shopping. Users of online shopping were also noticed to pay a considerable attention to aspects related to variety products presented online in comparison with non-users of online shopping. Clemes et al. (2003) have empirically proved the significant impact of product variety on the customer adoption of online shopping. Thus, the following hypothesis proposes that:

H9: Product variety will have a positive impact on the customer's intention to adopt online shopping.

RESEARCH METHODOLOGY

Participants and Procedure

Data were collected by means of self-administrated questionnaire containing 46 items from 388 online shopping users from England using a convenience sampling technique between February and April 2015. Consent was deemed to be given by participants who indicated that they agreed to take part in this research and that their participation in this study is voluntary. All responses were anonymous and on average, each participant took about 16 minutes to complete the questionnaire. No financial incentive or rewards in kind was offered for completing the survey. The sample age range varies from the mean age range varies from 18 to 52 years old, with 216 (55.67%) Male, and 323 (83.25%) were either has experienced or has some experience in using computers and internet usage.

Instrument

The items used in the proposed research model were adapted from previous studies related to technology adoption and online shopping. More specifically, performance expectancy and effort expectancy were measured using five items, whereas social influence and behavioural intention were measured using four items. These items were adapted from Venkatesh et al. (2012) and related work Venkatesh and Zhang (2010), Mandilas et al. (2013), Zolait (2014), Agrebi and Jallais (2015), Pascual-Miguel et al., (2015). Service quality was measured using four items and was adopted from Chang et al. (2005) and Clemesn et al. (2014). In addition, compatibility, convenience and product variety were also measured using four items and adopted from the work of Lin (2007), Prasad and Aryasri (2009), Amaro and Duarte (2015), Mee and Huei (2015). Finally, TR and PG were measured using four items and were adopted from the work of Koyuncu and Bhattacharya (2004), Yingjiao and Paulins (2005) and Clemesn et al. (2014).

All questions were measured using 7 points Likert scale, ranging from 1-strongly disagrees to 7-strongly agree.

DATA ANALYSIS

This section presents an in-depth analysis of the relationships among the constructs within the proposed research model. Two steps were used during the data analysis process as recommended by Hair et al. (2010). In the first step, the confirmatory factor analysis (CFA) was employed to assess the constructs' validity and reliability and test the model fit. The next step employed the structural equation modeling (SEM) technique to test the hypothesised relationships among the independent and dependent variables. Using a two-step approach assures that only the constructs retained from the survey that have good measures (validity and reliability) will be used in the structural model (Hair et al., 2010).

Descriptive Analyses

Overall, all means were greater than 3.84 which indicate that the majority of participants express generally positive responses to the constructs that are measured in this study. In addition, the standard deviation (SD) values ranged from 1.12 to 1.71 which showed a fairly narrow spread around the mean (see Table 1).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Descriptive statistics of the constructs

Construct	Mean	Standard Deviation
Performance Expectancy (PE)	5.46	1.31
Effort Expectancy (EE)	5.32	1.55
Social Influence (SI)	3.84	1.34
Trust (TR)	4.58	1.28
Product Guarantee (PG)	5.41	1.12
Compatibility (COMP)	4.03	1.42
Convenience (CON)	5.24	1.57
Service quality (SrvQ)	5.38	1.24
Product Variety (PRDV)	5.06	1.63
Behavioural Intention (BI)	5.31	1.71

Analysis of Measurement Model- Examination of Reliability and Validity

A confirmatory factor analysis (CFA) using AMOS 21.0 (Arbuckle, 2009) was conducted to test the measurement model. This study adopted maximum-likelihood estimation (MLE) procedure to estimate the model's parameters where all analyses were conducted on variance-covariance matrices (Hair et al., 2010). The overall model fit was assessed by five goodness-of-fit indices as recommended by Byrne (2013). Table 2 presents the fit indices of the measurement model and the structural model, all of which met the recommended guidelines and suggested a good model fit. The next step is to assess convergent validity, discriminant validity and reliability in order to evaluate if the psychometric properties of the measurement model are adequate.

Table 2. Model fit summary for the measurement and structural model

Fit Index	Recommended Value Hair et al., (2010)	Measurement Model	Structural Model
χ^2 / df	< 5 preferable < 3	2.78	2.76
Tucker-Lewis Index (TLI)	> 0.90	.948	.951
Comparative Fit Index (CFI)	> 0.90	.932	.934
Standardised Root Mean Square Residuals (SRMSR)	< 0.08	.075	.074
Root Mean Square Error of Approximation (RMSEA)	< 0.08	.046	.044

Construct Reliability, Convergent Validity, and Discriminant Validity

Convergent validity refers to the degree to which two measures of constructs that theoretically should be related, are in fact related (Gefen, Straub & Boudreau, 2000). This will ensure unidimensionality of the multiple-item constructs and will help in eliminating any unreliable indicators (Bollen, 1989).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Whereas, Discriminant validity measures the extent to which constructs differ (Gefen et al., 2000). Hair et al. (2010) states that reliability, convergent validity and discriminant validity can be assessed using composite reliability (CR) and average variance extracted (AVE). According to Kline (2010), a value of 0.7 and above for CR indicate an adequate reliability. In addition, the AVE should be equal or exceed 0.5 and CR is greater than the AVE in order to establish convergent validity. Whereas, the total AVE of the average value of variables should be greater than their correlation value in order to establish adequate discriminant validity (Hair et al., 2010). As can be shown in Table 3, the AVE of all the constructs were above 0.539 and above 0.757 for CR and this indicate that the constructs had adequate reliability and convergent validity. Also, the square root of AVE is higher than their correlation values which indicate that all the constructs in the proposed research model are deemed to be adequate.

Table 3. Construct reliability, convergent validity and discriminant validity

	CR	AVE	PG	PE	EE	SI	COMP	SerQ	CON	BI	TR	PRDV
PG	0.911	0.72	0.848									
PE	0.909	0.714	0.592	0.845								
EE	0.942	0.765	0.627	0.641	0.875							
SI	0.826	0.614	0.451	0.497	0.486	0.784						
COMP	0.764	0.539	0.617	0.634	0.782	0.593	0.84					
SerQ	0.878	0.707	0.135	0.185	0.093	0.037	0.114	0.841

TR	0.917	0.736	0.496	0.442	0.502	0.427	0.554	0.114	0.44	0.573	0.858	
PRDV	0.757	0.587	0.36	0.392	0.349	0.446	0.397	0.113	0.241	0.347	0.266	0.622

(Factor Correlation Matrix with $\sqrt{}$AVE on the diagonal)

Testing of Hypotheses

The next step after establishing good convergent and discriminant validity was to assess the structural model to test hypothesised relationships.

The results in Table 4 indicate that BI was influenced by PE, CON, SerQ, TR, PG, PRDV and COMP, in their order of influencing strength and all together accounted for 70.4% of the variance in BI. The obtained results indicate that H1, H3, H4, H5, H6, H7, H8, and H9 were supported. Contrary to our expectations, EE and SI did not have an influence on BI. Hence, H2 and H3 were not supported in this study.

CONCLUSION

This study was conducted with intention to provide further evidences clarifying the adoption of online shopping by UK customers. Indeed, a comprehensive model comprising the most important aspects that could shape the UK customer decision to use such innovative system was the focus of attention of this study. Therefore, factors from UTAUT2 and DeLone-McLean model of IS Success with trust (TR), product variety (PRDV) and product guarantee (PG) were proposed in the current study model. Empirically, statistical results largely support the conceptual model as all fit indices were found to be within their recommended level as well as the model ability to predict about 70.4% of variance in the behavioral intention.

In terms of path coefficient analyses, most factors proposed in the conceptual model were found to be significant in predicting the UK customers' intention to adopt online shopping. Accurately, PE was able to be the most influential factor with coefficient value of 0.18. This evidently expose that the willingness of UK customers to adopt online shopping strongly derived by the extent of how much benefits and utilities perceived in using online shopping. In fact, customers are increasingly noticed to value the modern ways in doing their shopping as well as they are more likely to be concerned regarding the time and efforts spent to do such shopping activities using physical brick and mortar stores. Therefore, it could logical justify why the usefulness and benefits of using online shopping are one of the most important aspects shaping customers' willingness to use online shopping. Theoretically, most studies conducted over the relevant area (i.e. Lin, 2007; Mandilas et al., 2013; Chong et al., 2012; Ingham et al., 2015; Agrebi & Jallais, 2015; Vijayasarathy, 2004; Rauniar et al., 2013; Pascual-Miguel et al., 2015) have provided strong evidences regarding the important role of PE or its captured factors in accelerating the behavioral intention to use online shopping.

With regression weight of 0.172, CON was the second strongest factor influencing the customer willingness to adopt online shopping. This implies that customers highly appreciate the aspects related to the ability of such system in making the shopping experience more convenient and much easier as customer can electronically purchase their needed items at any time from any place. Such issues con-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

tribute to the benefits captured via using online shopping as discussed regarding the role of PE, and accordingly accelerating the customers' intention to use online shopping. Over the prior literature, the role of CON has been proven to be key determinant of the customers' decision to adopt online shopping as reported by Clemes et al. (2014); Prasad and Aryasri (2009); Soopramanien and Robertson (2007); Richard (2005); Mee and Huei (2015); Kim et al. (2009); Chen et al. (2010); and Liang and Lai (2002).

SerQ was among the most influential factor determining the UK customers' willingness to adopt online shopping as well. Indeed, aspects related to service quality have been always the focus of attention for customers and users of website (DeLone & McLean, 1992). To put differently, the extent of how much the targeted website has more security, reliability, sympathetic, and creditability is crucial in enhancing the customer's penchant to adopt commercial website. This is also in addition to the fact that customers are more interested regarding the level of individualization and interactivity that could be captured through using online shopping. Practically, and as discussed in the conceptual model, aspects related to the website SerQ are not only important in predicting the behavioral intention but also in the forming the overall customers' perception toward such website. Therefore, results of the current study are logically justified as well as in the line with what has been approved by IS and online shopping studies (see DeLone & McLean, 1992; Gao et al., 2015; Liao et al. 2001; Vijayasarathy & Jones, 2000; Yang & Jun, 2002; Lee & Lin, 2005).

The UK customers' intention was noticed to be significantly predicted by trust, which means that UK customers are highly motivated to use online shopping if they perceive such technology as trustworthy and dependable to do their shopping. Since Gefen et al. (2003) included and approved trust as an integral construct alongside TAM factors, many studies over the IS and technology acceptance area have proven trust to have a significant impact on the behavioral intention to use different systems and applications. In fact, using online shopping usually requires customer to disclose their private information. Therefore, customers are less likely to disclose their information without a certain level of integrity and benevolence existing in the targeted website. Theoretically, several studies examining the adoption of online shopping have provide solid evidences supporting the role of trust in forming customers' decision to adopt online shopping as stated by Chen et al. (2015); Ingham et al. (2015); Chiu et al. (2012); and Hong and Cha (2013).

Product guarantee was also able to considerably influence the UK customers' intention to adopt online shopping. This means that customers are more willing to depend on such innovative system if they have more assurance guaranteeing the outcomes of using online shopping. This is especially with the absence of hand on experience as well as inability of customer to physically inspect product prior purchasing it (Koyuncu & Bhattacharya, 2004). Indeed, the importance of product guarantee will reach the high level for such kind of highly expensive products that comprises a high degree of risk (Koyuncu & Bhattacharya, 2004). Such thought supporting the impacting role of product guarantee has been largely examined and confirmed by many researchers such as Clemes et al. (2014); Yingjiao and Paulins (2005); and Koyuncu and Bhattacharya (2004).

By the same taken, a significant path was observed between product variety and customer's intention to adopt online shopping. Unlike traditional way of shopping where customer is restricted by few number of products, many more products at different level of quality and prices as well as from many brands are usually available over the online platforms. Therefore, with less time and efforts, customers are more able to have many alternatives, do a comparative process, and select the optimal product. Many researchers (i.e. Szymanski & Hise, 2000; Hoch et al., 1999; Van Herpen & Pieters, 2002; Cho, 2004; Sin & Tse, 2002; Jensen, 2009; Amaro & Duarte, 2015) assured that product variety is one of the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

main dimensions that make customer perceive using online shopping more useful and better than the traditional way of shopping.

Compatibility was the least significant factor predicting the UK customers' intention to adopt online shopping. Increasingly, individuals get more involved with different kinds of technology and more likely to perceive a technology an integral part of their daily life. So that, online shopping is considered as growing technology that is increasingly adopted by customers. This is especially over the developed countries like UK, which in turn, makes such innovative system as more compatible and consistent with customer experience, value, and behaviour. Such results regarding the significant influence of compatibility are in the line with proposition of Rogers (2003) who asserted such strong association between compatibility and individuals' decision to accept or reject new innovation. By the same taken, different online shopping studies (i.e. Vijayasarathy, 2004; Lin, 2007) have validated the impacting role of compatibility as well. This provides further evidences that boost including compatibility among the conceptual model proposed in the current study.

On the other side, efforts expectancy was rejected to have a significant influence on the behavioral intention. That means the UK customers are less concerned regarding the issues related to the extent of much using online shopping is easy to use and complexity. Such results could be returned to the fact that people either worldwide or particularly in the developed countries (i.e. UK) get more engaged with different kinds of technology and as a result of increasing their daily interaction with technology. Therefore, people have a knowledge and experience that enable them to override any complexity or barriers associated with using new systems. This is in the line with what was proposed by Davis et al. (1989) who indicated that the role of perceived ease of use is usually mediated by the impact of perceived usefulness. The nonsignificant influence of effort expectancy has been noticed by different studies that have adopted the UTAUT as a theoretical foundation (i.e. Alalwan et al., 2016; Zhou et al., 2010; Abu-Shanab et al., 2010; Mandilas et al., 2013).

Social influence was also another factor failed to statistically predict the UK customer's intention to adopt online shopping. To put differently, the UK customers seem to be not influenced by the impact of social environment surrounding them. As people have more experience and knowledge, they are more likely to depend on themselves rather than other to take a decision to use or reject a new system. Even though such results are in contrast to with other studies that have approved the role of social influence in shaping customer's intention (i.e. Lin, 2007; Chong et al., 2012; Clemes et al., 2014; Ingham et al., 2015), they were similar to other studies have noticed the same non-significant path (i.e. Alalwan et al., 2016; Lin, 2007; Mandilas et al., 2013; Pascual-Miguel et al., 2015).

Theoretical and Practical Contributions

Online shopping is an innovative system over the marketing area and the successful implementation of such system alongside with adequate rate of adoption will benefit both parties' firms and customers. Therefore, current study was conducted with intention to provide guidelines that hopefully could help organization to accelerate the acceptance of online shopping. According to the statistical results of the current study, there are a number of factors that have to be the focus of attention by marketers and designers. For instance, performance expectancy has received a great deal of interest by customers. Thus, further attention should be paid for the aspects related to the benefits captured by using online shopping. In this regard, marketers should work hard to convince their customers that using online shopping can save their time and efforts relative to the traditional way of shopping. As well as, designers should expand

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the number of services and benefits provided through this channel. Convenience was also an important factor considered by the UK customers. Therefore, the online shopping website should be enjoyed with high the degree of accessibility that enables customers to access these website from using any platforms (i.e. PC, IPad, smart phone) and therefore, customers can do their online shopping whenever and wherever and using any application are available them. Trust was another important issue that could shape the customer decision to use online shopping. Indeed, customer trust will not only impact the customer intention to use online shopping but also will have a future influence on the customer relationship with firms provided their products electronically. This in turn gives clues for firms to spend more efforts in designing their website secure way protecting their customer privacy and information. In this regard, Mohammad et al. (2003) provided number of mechanisms that could help firms to enhance the level of customer trust such as using firms well-known mother brands, third party rating, concentrating more on the customer service, using advanced technology, using encryption and authentication technologies. Results of the current study have provided indication about the important role of product variety. Accordingly, firms should work hard to have more products from different brands at different level of prices which in turn, can attract different segments of customers. Service quality was one of the main factors determining the customers' intention to use online shopping. Hence, the main dimension of this factor has to be developed in a way that could enhance the customer perception toward such system. For instance, firms have to increase the speed where customer requires less time to download the webpage of the screen as well as, firms must decrease problems related to downtime and system crashes. The website ability to be customized by customer should be also enhanced as well as more interactivity should exist in the website. Further, firms have to concentrate to accelerate the level of compatibility online shopping technology. This could be reach by educating customer how the can use such system in addition to enhancing customer experience in this regard. More importantly, firms have to spend more promotional and marketing efforts to let their customer perceive these technologies positively and appropriate with their value, culture, and other technologies used by them. Also, firms have to provide the adequate facilities and technical infrastructural that will help customers to easily and effectively use online shopping.

Limitations and Suggestion for Future Studies

This study has some limitations that should be acknowledged. Firstly, the generalizability of our results to other settings or user groups should be considered with cautious. Future research may verify the generalizability of our findings to other technologies and/or user groups or different developing/developed countries. Secondly, data was collected through a cross-sectional study which limits the ability to measure the temporal changes of the proposed factors over time, especially when the experience of users increase. Therefore, a longitudinal analysis could be performed which allows the factors effecting IB adoption to be monitored and compared over time. Finally, the values of R^2 for BI indicate that there may be a need to explore additional potential factors to better explain the variance in BI. For example, future research can build on our study by including other relevant factors (e.g. self-efficacy, Financial Cost, Resistance to change, Habit) or integrates a set of moderators (e.g. culture, income, educational level) in order to increase the predictive power of behavioral intention in the proposed model.

Chapter 20
Design Methodology for Effective User Interface Design for E-Commerce Applications

Namratha Birudaraju

Anurag Group of Institutions, India

ABSTRACT

There are many customers who shop online. Many of these users interact with the system using well-defined user interfaces only. So, there is a need to develop effective user interfaces that are more user friendly, minimize the keyboard operations, and maximize effective interaction with the system. This chapter focuses on designing effective user interfaces by considering human parameters for e-commerce applications.

INTRODUCTION

Electronic commerce is the application of communication and information sharing technologies among trading partners to the pursuit of business objectives. E-Commerce can be defined as a modern business methodology that addresses the needs of organizations, merchants, and consumers to cut costs while improving the quality of goods and services and increasing the speed of service delivery. E-commerce is associated with the buying and selling of information, products and services via computer networks. The effects of e-commerce are already appearing in all areas of business, from customer service to new product design. It facilitates new types of information based business processes for reaching and interacting with customers – online advertising and marketing, online-order taking and on-line customer service etc. It can also reduce costs in managing orders and interacting with a wide range of suppliers and trading partners, areas that typically add significant overhead to the cost of products and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

services. Also, E-commerce enables the formation of new types of information-based products such as interactive games, electronic books, and information-on demand that can be very profitable for content providers and useful for consumers. The explosion in the use of electronic commerce (e-commerce) by the business sector has been tremendous since its inception only a few years ago. From governments to multinational companies to one-person start-ups, e-commerce is increasingly viewed as a key business modality of the future. Ease of transaction, widening markets, and decreased overheads are factors that make e-commerce solutions more and more attractive, as evident with the growth of online sales. Virtual enterprises are business arrangements in which trading partners separated by geography and expertise are able to engage in complex joint business activities, as if they were a single enterprise. One example would be true supply chain integration, where planning and forecast data are transmitted quickly and accurately throughout a multi-tier supply chain. Another example would be non-competing suppliers with a common customer using E-commerce to allow that customer to do "one stop shopping" with the assurance that a single phone call will bring the right materials to the right location at the right time.

Development of E-Commerce (EC) applications started in the early 1970s with electronic funds transfer (EFT), which refers to the computer-based systems used to perform financial transactions electronically. However, the use of these applications was limited to financial institutes, large corporations, and some businesses. Electronic data interchange (EDI) was then developed in the late 1970s to improve the limitation of electronic funds transfer. Electronic data interchange enlarged the pool of participating company from manufacturers, retailers, services, and others. Such systems were called Interorganizational System (IOS). An Interorganizational System (IOS) allows the flow of information to be automated between organizations to reach a desired supply-chain management system, which enables the development of competitive organizations.

The user interface design of website plays a vital role in bringing high volume web traffic to it. Therefore, web designers should give due importance to the user interface of the site which is being designed by them. The use of effective and simple user interface design will be of immense help in achieving the objectives of a website. A good user interface not only increases the site usability but also leads to the smooth completion of any task at hand thereby making everything enjoyable and flexible as per the requirements of users. A fundamental reality of application development is that the user interface is the system to the users. What users want is for developers to build applications that meet their needs and that are easy to use. Constantine (1995) points out that the reality is that a good user interface allows people who understand the problem domain to work with the application without having to read the manuals or receive training. Interface design is important for several reasons. First of all the more intuitive the user interface the easier it is to use, and the easier it is to use the cheaper it is. The better the user interface the easier it is to train people to use it, reducing training costs. The better the user interface the less help people will need to use it, reducing support costs. The better the user interface the more users will like to use it, increasing their satisfaction with the work that have done.

The design of interfaces that attempt to encompass an extensive amount of merchandise has to employ methods where the product is either display successfully in a smaller scope while retaining its informational value. When it comes to e-commerce, User Interface design makes a difference between customers who abandon their carts and the ones that place an order. Elements like high quality product images are useful to persuade users to make a purchase. Clear call to action buttons and Seamless checkouts demonstrate that graphic and intuitive design must combine to make user navigation easy to use. Attention to user interface design details like the shopping cart, images, and call to actions will increase purchases and boost customer satisfaction.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The web interface becomes a major success factor since customers interface with sellers in cyberspace through the seller's website. There were many of consumer reports frustrations with the lack of interface standard features within e-commerce websites. This phenomenon makes e-commerce sites lose up to 50% of potential online sales because users cannot find what they want.

BACKGROUND

User interfaces are inputs and outputs that more directly involve a system user. Their design varies widely depending on such factors as interface purpose, user characteristics, and characteristics of a specific interface device (Hughes, Brusilovsky & Lewis, 2002).

As increasingly more products and services are sold over the Internet, it becomes all the more important to build up knowledge in e-commerce-specific user interface (UI) and user experience (UX) design. The entire user experience must therefore be designed to induce a positive affective state by strategically addressing consumers' concerns.

In order to explore issue of user interface, identify and analyze features of user interfaces and common location of e-commerce function on e-commerce web sites. In e-commerce, the website is the firm's interface with the customer, and its usability is crucial to the success of the venture (Turban & Gehrke 2000). The web is the primary infrastructure for e-commerce and offers some advantages.

E-commerce site should focus on being functional in navigation and interface, facilitate purchasing speed for both repeat customers and new purchases, be as direct as possible with minimal monetization through advertisements, and put a premium on data security to promote customer confidence in making a purchase through the software.

First, a web site enhances the corporation's image and improves communications with other corporations, thus improving efficiency in business process and reducing cost (Alper, 1999; Zona Research, Inc., 2000). Second, customer interface with sellers in cyberspace through the sellers' web site, therefore a well-constructed web site can determine the user's willingness to stay in a site, revisit it, and buy on the net.

Whereas a poorly constructed web site can lead to lost revenues and negative effect on corporate image (Zona Research, Inc., 2000).

Although there have been many studies focusing on the importance of web site design features (Huang et al., 2006; Kim et al., 2003; Tarafdar & Zhang, 2006; Turban & Gehrke, 2000), there have been few studies that have sought to identify the standard features of user interface in ecommerce web sites.

E-Commerce website design involves complex issues, including shopping carts, large catalogues, payment security issues, etc. Some authors suggest that certain features that make a website effective must be included. Coopee et al (2000) recommend that websites include easy payment processing and website security user tracking. Also: the company information must be easy to find online, customers must have reason to visit the website, the site must be visually appealing to users and navigation must be clear and simple (Cell 2000).

According to Najjar (2001), search, contact us, registration and shopping carts are major features of an e-commerce website. Cyr et al (2004) points out that users have differences in preferences of website design, access to product details, navigation and availability of products.

There are many individuals and organizations have published their own sets of guidelines. Entering the keywords "web design guidelines" into an internet search engine returns about 7,860,000 hits. The

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

objective of these guidelines is to help designers make a better design decision that will result in a more usable or useful design. However, many of those guidelines are abstract and open to broad interpretation. Determining what kind of empirical support is available for web design guidelines is particularly challenging.

From 1990s onwards, electronic commerce would additionally include enterprise resource planning systems (ERP), data mining and data warehousing. The term 'electronic commerce' was coined in the early 1990s when Internet became commercialized and users began flocking to participate in the World Wide Web. The earliest example of many-to-many electronic commerce in physical goods was the Boston Computer Exchange, a marketplace for used computers launched in 1982. The first online information marketplace, including online consulting, was likely the American Information Exchange, another pre-Internet online system introduced in 1991.Since 1995, many innovative applications, ranging from direct online sales to e-learning experiences had been developed. Almost every organization in the world has a Web site. In 1999, the emphasis of e-commerce shifted from Business-to-Consumer (B2C) to Business-to-Business (B2B). In 2001, from B2B to B2E, e-government, e-learning, and m-commerce. In 2005, social networks started to rise and so did e-commerce and wireless applications-e-commerce will undoubtedly continue to shift and change in the future (ECommerze, 2008).

The Table 1 describes the evolution of e commerce.

Table 1. Evolution of e-commerce

Year	Event
1984	EDI, or electronic data interchange, was standardized through ASC X12. This guaranteed that companies would be able to complete transactions with one another reliably.
1992	CompuServe offers online retail products to its customers. This gives people the first chance to buy things off their computer.
1994	Netscape arrived. Providing users a simple browser to surf the Internet and a safe online transaction technology called Secure Sockets Layer.
1995	Two of the biggest names in e-commerce are launched: Amazon.com and eBay.com.
1998	DSL, or Digital Subscriber Line, provides fast, always-on Internet service to subscribers across California. This prompts people to spend more time, and money, online.
1999	Retail spending over the Internet reaches $20 billion, according to Business.com.
2000	The U.S government extended the moratorium on Internet taxes until at least 2005.

E-Commerce Pioneers

Companies such as eBay and Amazon began to lead the way in e-commerce, both were among the first to establish prominent e-commerce brands. The most prominent e-commerce categories today are computers, books, office supplies, music, and a variety of electronics.

Amazon.com, Inc., founded by Jeff Bezos, was the original e-commerce pioneer and certainly the most recognizable. In the beginning, Amazon's business model required massive investment in warehousing, delivery and fulfillment capability and took years for Amazon to gain profitability.

Amazon began as just an online bookstore but over the years has extended its offering to a wide variety of product categories, including electronics, software, music, DVD's, CD's, video games, MP3's, cloth-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ing, shoes, health and beauty products and even household goods. Today, Amazon generates anywhere between 30 to 40% of its total sales revenue from affiliates or third party merchants who list and sell their products on Amazon's web site.

User Interface and Its Principles

User Interface (UI) Design focuses on anticipating what users might need to do and ensuring that the interface has elements that are easy to access, understand, and use to facilitate those actions. UI brings together concepts from interaction design, visual design, and information architecture.

Understanding the User Interface

1. **User-Centered Design:** Design techniques that embody the view that the user interface is the entire system.
2. **Usability:** Degree to which a system is easy to learn and use.
3. **Metaphors:** Analogies between features of the user interface and aspects of physical reality that users are familiar with.
4. **Direct Manipulation Metaphor:** Metaphor in which objects on a display are manipulated to look like physical objects (pictures) or graphic symbols that represent them (icons).
5. **Desktop Metaphor:** Metaphor in which the visual display is organized into distinct regions, with a large empty workspace in the middle and a collection of tool icons around the perimeter.
6. **Document Metaphor:** Metaphor in which data is visually represented as paper pages or forms.
7. **Dialog Metaphor:** Metaphor in which user and computer accomplish a task by engaging in a conversation or dialog via text, voice, or tools such as labeled buttons.

User Interface Design Principles

User Interface needs to be streamlined and easy to use for novice users, it should also not be boring for experienced and educated ones. Constantine and Lockwood describe a collection of principles for improving the quality of your user interface design. These principles are:

1. **The Structure Principle:** Your design should organize the user interface purposefully, meaningfully, useful ways based on clear, consistent models that are apparent, and recognizable to users, putting related things together and separating unrelated things, differentiating dissimilar things and making similar things resemble one another.
2. **The Simplicity Principle:** Your design should make simple, common tasks simple to do, communicating clearly and simply in the user's own language, and providing good shortcuts that are related to longer procedures.
3. **The Visibility Principle:** Your design should keep all needed options and materials for a given task visible without distracting the user with extraneous or redundant information.
4. **The Feedback Principle:** Your design should keep users informed of actions or interpretations, changes of state or condition, and errors or exceptions that are relevant and of interest to the user through clear, concise, and unambiguous language familiar to users.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

5. **The Tolerance Principle:** Your design should be flexible and tolerant, reducing the cost of mistakes and also preventing errors wherever possible by tolerating varied inputs.
6. **The Reuse Principle:** Your design should reuse internal and external components maintaining consistency with purpose rather than merely arbitrary consistency, thus reducing the need for users to rethink and remember.

Choosing Interface Elements

Interface elements include but are not limited to:

- **Input Controls:** These controls are used to select, sort or search particular items in. Examples are: buttons, text fields, checkboxes, radio buttons, dropdown lists, list boxes, toggles, date field
  - **Text Box:** A rectangular box that accepts text typed on a keyboard or recognized from speech input
  - **List Box:** A text box that contains a list of predefined data values
  - **Combo Box:** A text box that contains a predefined list of acceptable entries but permits the user to enter a new value when the list doesn't contain the desired value
  - **Radio Buttons:** A group of choices from which the user selects only one; the system then automatically turns off all other buttons in the group
  - **Check Boxes:** Similar to radio buttons, but the user can select multiple items within the group
  - **Cascading Style Sheets (CSS):** Web page encoding standard that enables a Web site designer to specify parts of a page that will always look the same and parts that will vary by task or audience
  - **Assistive Technologies:** Software (such as text-to-speech and voice-recognition utilities) that adapts user interfaces to the special needs of persons with disabilities
- **Navigational Components:** These are used to move or navigate from one page to other.
  - **Examples:** Slider, search field, pagination, tags, icons
- **Informational Components:** These are used to provide information to the user.
  - **Examples:** Tooltips, icons, progress bar, notifications, message boxes.
- **Containers:** There are times when multiple elements might be appropriate for displaying content. When this happens, it's important to consider the trade-offs.

Defining a User Experience

Here are some of the elements that impact the user experience of your online store.

- Visual appeal. Colors, branding, imagery, layout.
- Search and navigation. Ability to find what you are looking for quickly.
- Site map. How the site is categorized and grouped.
- Content. Quality and quantity of text, images, videos that are associated with products and product categories.
- Ease of use. Can users easily navigate across the site, in and out of the cart, create shopping lists, find shipping costs?

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Availability of help. Online chat, email help, self service accounts.
- Performance. Is the site fast?
- Payment options and process. Do you offer several payment methods, can users store credit card information, checkout with PayPal Express or other 3rd party payment systems?
- Shopping cart. Is it visually appealing? Is shipping info available?
- Image features. Zoom and pan, alternate images?
- Personalization. Is the store delivering personalized content?
- Merchandising. Are promotional items well displayed and available, using best-seller lists, cross-sells, and up-sells?
- Sale of goods
- Purchase of goods
- Financial assistance
- Advertising
- Sharing of products

The reality is the user experience is impacted by every single element of your website. You can have a well designed site with great navigation and performance, but if your shopping cart is lacking a shipping estimator, you may lose buyers to a poorly designed site that includes one.

Best Practices for Designing an Interface

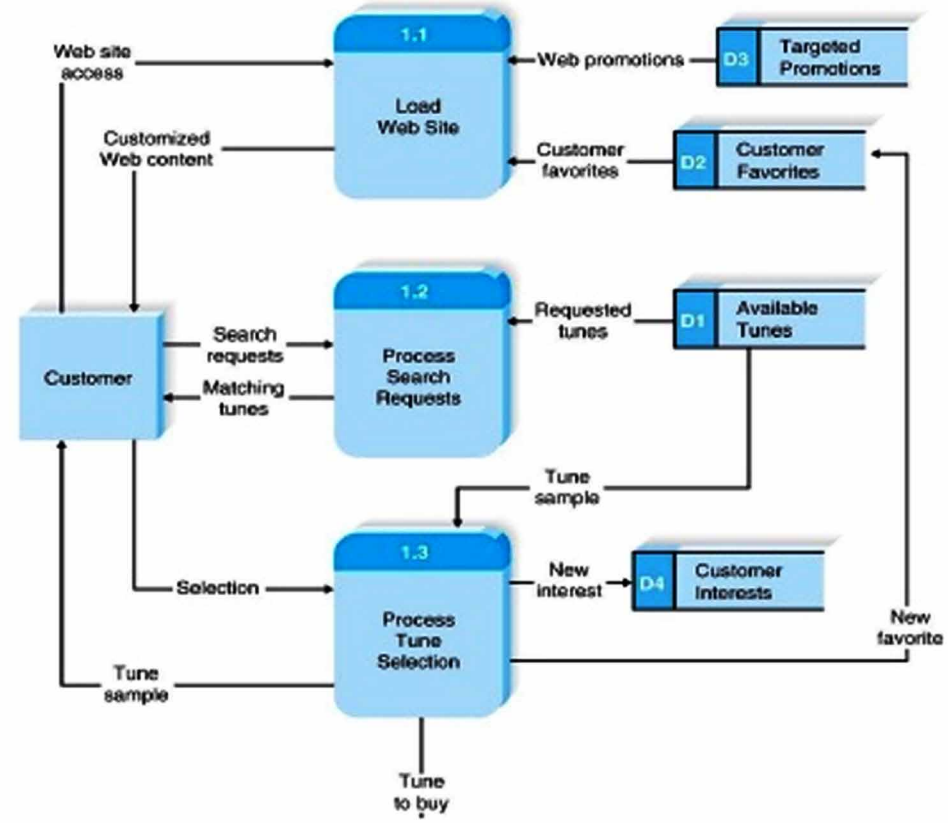
Once you know about the user, make sure to consider the following when designing the interface:

- **Keep the Interface Simple:** The best interfaces are almost invisible to the user. They avoid unnecessary elements and are clear in the language they use on labels and in messaging.
- **Create Consistency and Use Common UI Elements:** By using common elements in your UI, users feel more comfortable and are able to get things done more quickly. It is also important to create patterns in language, layout and design throughout the site to help facilitate efficiency.
- **Be Purposeful in Page Layout:** Consider the spatial relationships between items on the page and structure the page based on importance. Careful placement of items can help scanning and readability.
- **Strategically Use Color and Texture:** You can direct attention toward or redirect attention away from items using color, light, contrast, and texture to your advantage.
- **Use Typography to Create Hierarchy and Clarity:** Different sizes, fonts, and arrangement of the text to help increase scanability, legibility and readability.
- **Make Sure That the System Communicates What's Happening:** Always inform your users of location, actions, changes in state, or errors. The use of various UI elements to communicate status and, if necessary, next steps can reduce frustration for your user.
- **Think About the Defaults:** By carefully thinking about and anticipating the goals people bring to site, you can create defaults that reduce the burden on the user.

Figure 1 explains user interface design process with an example.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. User interface design process example



Guidelines for Designing Windows and Forms

Interface Layout and Formatting

High-quality interfaces are well laid out, with the fields easily identified and understood. As you design your interfaces, you should think about these:

- **Consistency:** All the forms within a system need to have the same look and feel.
- **Labels and Headings:** Labels should also be easy to identify and read.
- **Distribution and Order:** Related fields are usually placed next to each other and can be grouped within a box.
- **Fonts and Colors:** Variations in font face and size can help users distinguish different parts of the form, but only a handful of font and size variations should be used for larger screens and as few as possible should be used for small screens.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Data Entry

Several types of data-entry controls are widely used in user interfaces, including Text boxes, List boxes, Combo boxes, Radio buttons, and Check boxes.

Guidelines for Web Browser User Interfaces

Consistency

Consistency is especially critical within Web sites because most sites contain a large number of pages that serve many different purposes and audiences. Cascading style sheets (CSS) are a Web page encoding standard, and they enable a Web site designer to specify parts of the site's pages that will always look the same and parts that will vary by task or audience.

Performance Considerations

Performance considerations are also an important issue in Web applications. Web sites in general and browser-based forms in particular are sensitive to application design and to the quality of the network connections between the user's computing device and the servers that host the site. Designers of Web-based user interfaces must perform a careful balancing act, providing embedded programming code within a page to avoid refreshes but not overloading page content so as to avoid long delays when the user moves from page to page.

Pictures, Video, and Sound

Web-based interfaces are often preferred for their inherent ability to mix text, images, and sound. Powerful and compelling interfaces can be constructed, and they are especially important in customer-facing systems. However, heavy use of sound and images exacerbates the previously discussed performance issues and also creates issues of compatibility. Compatibility issues arise for sound and video because there are so many ways in which they can be encoded. Thus, Web site designers must carefully choose which formats and plug-ins will be used.

Users With Disabilities

Designers of all user interfaces must be sensitive to the special needs of persons with disabilities. Because the Web is such a fundamental resource in the modern world, standards have been developed to ensure maximal usability for those who are visually impaired or have limited dexterity. Providing this kind of support is part of the class of software called assistive technologies.

Guidelines for Handheld Devices

Designing Web and app-based user interfaces for handheld devices presents additional design challenges, including:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Small screen size
- Small keyboards and touch screens
- Limited network capacity
- App design guidelines and toolkits

The small screen area provides relatively limited space in which to display content. Thus, designers must pare down the user-interface content to ensure readability and to avoid cluttering the screen. Mobile device user interfaces must avoid detailed textual input whenever possible and must provide touch controls that are well spaced and easy to locate.

User Interface Perspective

Being concentrated on not only logic and transitions but also looks and style, UI design stage also contributes much to the success of the e-commerce project. It is the aspect which creates visual performance and sets the solid ground for the desirability of the interface and positive emotional feedback from the buyer. At UI design stage for e-commerce, designers have to find the general stylistic concept which will support UX aspects mentioned before and will give the online point-of-sale the attractive looks. Some aspects, which designers have to take into account in this perspective, are:

- Choice of colors that correspond to the brand image and strengthen emotional feedback
- Setting the style corresponding to the nature of the commercial offer:
- Reaching the website, people should instantly understand if it sells household goods, fresh vegetables, trendy clothes, exclusive devices or anything else
- Visual hierarchy which makes the core zones of interaction instantly noticeable.
- General harmony of perception which sets the feeling of aesthetic satisfaction supporting positive user experience.
- Simple check-list for some essential aspects designers would rather consider working on e-commerce projects:
    - **Know the Buyers:** User research will help to get the needs and wishes of target audience.
    - **Have Users Informed:** Make the screens or pages filled with information and functionality users really need for making purchase.
    - **Keep Design Consistent:** Not only does the website or app itself need consistency of design for all the screens in terms of general branding, but also social networks, print materials and actual point-of-sales appearance if they exist.
    - **Refresh the Experience:** Minor changes or attractive details added to the interface from time to time without breaking general visual consistency can give the feeling of refreshment, like new looks of mannequins do in the window displays of the shop.
    - **Check Your Solutions:** User testing can have a great impact on understanding the factors that boost conversions. Ideally, it should be applied not only in the process of design but also after the launch of e-commerce platform on the basis of real user interactions and troubles which can arise.
    - **Be Careful About Revolutions and Wow-Effect:** The power of habit plays the big role in the products of this kind. Choosing layout, menus or icons, which stand too far from the ones users are generally accustomed to, can bring confusion and frustration. For example, usage

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

of any other image instead of the magnifying glass to mark the search field can result in bad user experience as buyers know that visual symbol and will look for it. So, making this sort of experiments, take time to test them well.

- **Respect the Buyers:** Remember, that they are not abstract metrics-every figure in conversion report is about real people. Look for the interface that will respect their time, effort and needs and it will bring positive experience of shopping for both sides.

To summarize designing e-commerce website or mobile app, designers should definitely consider the following aspects:

- Operational simplicity
- Strong branding
- Security of users' data
- Effective use of visual elements
- Clear data presentation via menus, catalogs etc.
- User's ability to leave feedback about goods and services
- Easily available general and contact information about the business providing goods or services
- Design that supports the offer not overshadowing it.

Challenges of Designing a User Interface

Designing the user interface for an e-commerce site is very challenging. Various researches investigating the major determinant features of an effective web site have been done before. Some of them are explained below.

Coopee et al. (2000) suggested that web site designers should include some essential features into any commercial web site they design, as follows: catalog development, users tracking, payment processing, online fulfillment, web site security, privacy, business-business sales models, and business-customer sales models.

Cell (2000) provided some guidelines for creating customer friendly web site: make company easy to find online, keep site navigation simple and clear, give customers a reason to visit the site, make site visually appealing, offer a menu of communications options, and answer e-mail promptly and professionally.

Najjar (2001) stated that designing the user interface for an e-commerce site is very challenging. The major sections to design include the overall page format, navigation, catalog, registration, personalization, checkout, and customer service. In page format, he considers download speed, the use of graphics, scrolling, and highlighted that a web designer should format the page to make it easy for users to interact with the web site by put user interface elements in familiar locations.

Cyr et al. (2004) addressed differences in preferences and perception of web site design across culture. They considered menu layout, access to product info, professional design, logical info presentation, screen design, navigation, sequencing, product attributes, and product availability as an important web site features.

Liu et al., (2003) studied about standard user interface in e-commerce site found that the lack of a standard user interface that can assist users to navigate different e-commerce sites would influence the individual's decision to accept site for online shopping purpose. The results also show a strong relationship between users' perceptions of usefulness and ease of use toward standard user interface.

Challenges of E-Commerce Applications

Five biggest challenges for launching an e-commerce marketplace are:

1. Seller and buyer retention: The issue of buyer retention can only be solved with the help of marketing efforts, wide ranges of sellers and providing the best shopping experience.
2. How to connect buyers with relevant sellers: To solve this issue different practices and methods are used like:
    a. Modern behavior driven on-site search systems
    b. Personalized matching algorithms and trigger based emails
    c. Auto filling sellers accounts (and tips for their rational filling)
    d. Handy navigation
3. How to make buyers trust sellers: To build trust in your business you should take into account the testimonials, rating, social proof.
4. A Good First Impression: The first impression is the longest lasting, it's very important to provide the best user experience on any device.
5. Shopping experience: The best shopping experience is the essence of all above, with amazingly beautiful multi-device design, intuitive UI and personalization.

Context-based personalization is one of the main trends of the e-commerce in 2016. It can help to map the customer's journey and anticipate their needs, providing shoppers with the information they need, when they need it.

Standardized User Interface

The need to standardize user interface is:

1. Easy access
2. Effective web design
3. Understand web

Standards in web developments are of increasing importance as programmers strive to make their components work across all browsers and accessible by the broadest set of customers (Clary,2003).

A standard ensures users can understand the individual interface elements in an e-commerce site and that customers know where to look for what features. [2]Jakob's law of the web user experience

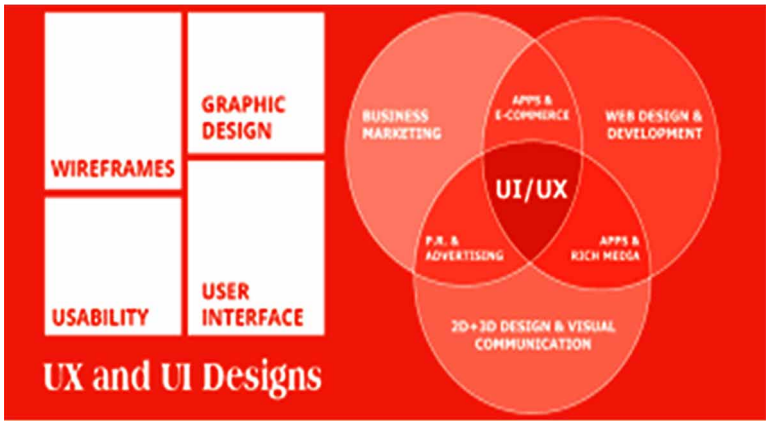
Jacob Nielsen states:"Users expect 77% of the simpler Web design elements to behave in a certain way". Three different standardization levels according to him are:

1. **Standard:** 80% or more of websites use the same design approach. Users strongly expect standard elements to work a certain way when they visit a new site because that's how things always work.
2. **Convention:** 50-79% of websites use the same design approach. With a convention, users expect elements to work a certain way when they visit a new site because that's how things usually work.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. **Confusion:** With these elements, no single design approach dominates, and even the most popular approach is used by at most 49% of websites. For such design elements, users don't know what to expect when they visit a new site.

Figure 2. User interface design



Wireframe

A wireframe is a simple line drawing depicting the layout of a website before any decoration is added. It outlines size, placement and orientation of every part of your Web page.

Graphic Design

Graphic design of e commerce website should be visually pleasing as well as functional, usable, and "lightweight" (fast –loading)

Usability

The goal of ecommerce Usability is to fulfill the customer's purchasing needs as quickly and effortlessly as possible. Usability helps to make the site experience seamless for the consumer, which increases sales. Usability powers good user interface design through a user-centered design approach that analyzes the entire ecommerce transaction from the customer's perspective.

User Interface

User Interface (UI) Design focuses on anticipating what users might need to do and ensuring that the interface has elements that are easy to access, understand, and use to facilitate those actions. Website usability is delivered through the user interface design.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

DESIGN OF USER INTERFACE

Prototyping

Prototyping (Ambler, 2001; Ambler, 1998a) is an iterative analysis technique in which users are actively involved in the mocking-up of screens and reports.

The purpose of a prototype is to show people the possible design(s) for the user interface of an application.

There are four steps to the prototyping process:

1. Determine the needs of your users. The requirements of your users drive the development of your prototype as they define the business objects that your system must support. You can gather these requirements in interviews, in CRC (class responsibility collaborator) modeling sessions, in use-case modeling sessions, and in class diagramming sessions (Ambler 2001; Ambler, 1998a; Ambler, 1998b).
2. Build the prototype. Using a prototyping tool or high-level language you develop the screens and reports needed by your users.
3. Evaluate the prototype. After a version of the prototype is built it needs to be evaluated. The main goal is that you need to verify that the prototype meets the needs of your users.
4. Determine if you're finished yet. You want to stop the prototyping process when you find the evaluation process is no longer generating any new requirements, or is generating a small number of not-so-important requirements.

Prototyping Tips and Techniques

1. **Look for Real-World Objects:** Good User Interfaces allow users to work with the real-world objects they are used to. Therefore you should start by looking for these kinds of objects and identify how people interact with them.
2. **Work With the Real Users:** The best people to get involved in prototyping are the ones who will actually use the application when it's done. These are the people who have the most to gain from a successful implementation, and these are the ones who know their own needs best.
3. **Set a Schedule and Stick to It:** By putting a schedule in place for when you will get together with your users to evaluate the prototype, you set their expectations and you force yourself to actually get the work done. A win-win situation.
4. **Use a Prototyping Tool:** Invest the money in a prototyping tool that allows you to put screens together quickly. Because you probably won't want to keep the prototype code that you write, code that's written quickly is rarely worth keeping, you shouldn't be too concerned if your prototyping tool generates a different type of code than what you intend to develop in.
5. **Get the Users to Work With the Prototype:** Just like you want to take a car for a test drive before you buy it your users should be able to take an application for a test drive before it is developed. Furthermore, by working with the prototype hands-on they will quickly be able to determine whether or not the system will meet their needs. A good approach is to ask them to work through some use-case scenarios using the prototype as if it is the real system.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

6. **Understand the Underlying Business:** You need to understand the underlying business before you can develop a prototype that will support it. Perform interviews with key users, read internal documentation of how the business runs, and read documentation about how some of your competitors operate. The more you know about the business the more likely it is that you'll be able to build a prototype that supports it.
7. **There are Different Levels of Prototype:** I like to successively develop three different types of prototypes of a system: A hand-drawn prototype that shows its basic/rough functionality, an electronic prototype that shows the screens but not the data that will be displayed on them, and then finally the screens with data. By starting out simple in the beginning I avoid investing a lot of time in work that will most likely be thrown away. By successively increasing the complexity of the prototype as it gets closer to the final solution, my users get a better and better idea of how the application will actually work, providing the opportunity to provide greater and greater insight into improving it.
8. **Don't Spend a lot of Time Making the Code Good:** At the beginning of the prototyping process you will throw away a lot of your work as you learn more about the business. Therefore it doesn't make sense to invest a lot of effort in code that you probably aren't going to keep anyway.

General Guidelines

- Be consistent in a user interface, it's critical.
- Set user interface standards and stick to them.
- Choose industry standards so as to increase the chance that your applications
- will look and feel like other applications developed externally to your organization.
- Explain the rules of how your application works to your users. If it's consistent,
- then the rules should be simple and few in number.
- Support both novices and experts.
- Word text consistently, positively, and in full English.
- Look at other applications with a grain of salt because not everyone understands good user interface design.
- Display the objects that your users need to do their jobs on the desktop.
- Think in terms of clusters of business objects and their corresponding interface objects, not in terms of applications.
- Interface objects should look, feel, and behave exactly like the real-world objects that they represent.

Screen Design

- Navigation between screens and on screens are both important.
- Understand your widgets so that you know how to apply them properly.
- Use color sparingly and always have a secondary indicator.
- Follow the contrast rule – put dark text on light backgrounds and light text on dark backgrounds.
- Use fonts sparingly and consistently.
- When items are unavailable gray them out, don't remove them if you want your users to form accurate models.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Use non-destructive default buttons.
- Left justify edit fields and right justify their labels.
- Right justify integers, decimal-align floating point numbers, and left justify strings.
- Don't create busy/crowded screens.
- Use group boxes and whitespace to group logically related items on the screen.
- Open windows in the center of the action.
- Pop-up menus shouldn't be the only source of functionality.

Experienced developers recognize the importance of all aspects of the user interface and recommend using several techniques that place the user at the center of the development process. These techniques are referred to collectively as user-centered design. User-centered design techniques emphasize three principles:

- Focus early on users and their work.
- Evaluate designs to ensure usability.
- Use iterative development.

The early focus on users and their work is consistent with the approach to systems analysis in this text. User-oriented analysis and design tasks are performed as early as possible and are often given higher priority than other tasks.

The goal of user-centered design is usability, the degree to which a system is easy to learn and use. Ease of learning and ease of use sometimes conflict. For example, a system can be easy to learn but be cumbersome to use all day. Usability is not always easy to achieve.

In general, the usability is a software quality attribute which measures the extent to which an application can be used by users to achieve effectiveness, efficiency and satisfaction in a specified context of use [3],[7]. Furthermore, the usability can be decomposed into five attributes:

1. Learnability, which measures the ease of learning the application functionality;
2. Efficiency, which measures the ease of use and the level of productivity attainable by the user;
3. Memorability, which measures the ease of remembering the application's functionality;
4. Low error rate, which measures how the application support users in making less errors; and
5. User's satisfaction, which measures how the users enjoy the application.

The third principle of user-centered design is iterative development-that is, doing some analysis, then some design, then some implementation, and then repeating the processes. After each iteration, the project team evaluates the work on the system to date. Iterative development keeps the focus on the user by continually returning to the user requirements during each iteration and by evaluating the system after each iteration.

There are many things that go into creating an optimal user interface design. Here's an overview:

- User Experience is the first and most strategic step to an optimized user interface design.
- User Experience conceptualization, planning, and design ensures the site will fulfill your business goals.
- The information architecture wireframes are the functional blueprints of the site.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- Information architecture also includes the careful planning and definition of the site's navigation, naming conventions and content organization.
- Usability helps to make the site experience as seamless as possible for the visitor to increase site engagement and sales.
- Usability powers good user interface design by promoting a user-centered design approach that analyzes the ecommerce transaction from the customer's perspective.

The design of web sites for effective performance is a complex and highly creative process that blends intuition, experience, and careful consideration of numerous technical issues and investigations (Nielsen, 2000; Sharma & Sharma, 2000; Sklar, 2000; Niererst, 1999).

Graphical features on the web are increasingly important to support information as well as interaction between consumers and business providers. Consumers are interested in information, representing style and interaction with web usage depending on the amount of graphical components. Graphical components support users' understanding and deter mination to purchase products from the web. In global markets, users are sensitive to interaction with product information on the web. Web designers provide information using text, colors, symbols and graphics on the web page.

Del Galdo and Nielson (1996) demonstrated that color and screen design directions have different psychological and social associations in different cultures. More importantly, different users have different concepts of screen usage. Because of the right-to left writing direction of the Arabic language, the common way to design the screen is to start reading from the top right-hand to the left-hand side (Del Galdo & Nielson, 1996). Designing screens normally needs to consider that Latin-based screen design starts from the top left and corner, and Chinese language can start from top right-hand to bottom left-hand or adopt the Latin-based style. However, it is very difficult to provide localized screen designs if they are not included in the original design of the application. As a result Graphic User Interface (GUI) applications need to be considered in localized interface design with globalized information on the web.

Although the cultural background of consumers is very important for interface design, current design practice takes minor account of cultural issues. Consumers' expectations are not taken into consideration in designing the functionality of web sites in Singapore. Singaporean designers emphasized that the graphics (pictures and animations) are important components and hence are heavily used to attract local customers. On the contrary, Australian web designers were less sensitive to the use of graphics on the web. However they preferred creating an image of the company on the web rather than using company's logo to reiterate company's image. Apparently Australian web designers are more customer-oriented in web design, in comparison to Singaporean web designers.

The web sites of leading IT companies did not have their interface to account for different user cultures. The web designers create graphic components on web sites lead to unique conventions leading to evolution of a new culture in expression of ideas on the web based e-market (WBEM).

CULTURAL ISSUES IN WEB DESIGNING

It helps to be able to quantify cultures. Importantly, this is not a way to make blanket statements about people from certain countries, but a way to clarify how groups interact with each other and the internet.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Designing an excellent user interface for one language in one country offers many challenges. Designing a user interface that can be successfully implemented for several language and several countries is even more difficult.

A company may wonder if it's even possible to design a single user interface that, when implemented, will provide an excellent user experience for the majority of the world's Internet users.

However, it remains an interesting questions to what extent web design should be complies with interface standards within different skill and cultural challenges. Following design standards simply ensures that users know what a company is talking about. User interface standards have become the object of increasingly intense activities in recent years [Abernethy 1988; Holdaway & Bevan 1989]. These activities are part of a general current interest in information processing standards [Berg & Schumny 1990].

Eliminate the confusing design elements and move as far as possible into the realm of design conventions will ensure users know what features to expect, know how these features will look in the interface, know where to find these features on the site and on the page, know how to operate each feature to achieve their goal, don't have to ponder the meaning of unknown design elements, don't miss important features because they overlook a non-standard design element. Cultural factors in information systems are likely to impact on effectiveness through user interface design.

Web interface design and user issues are significant factors in the measurement of systems implementation. Web implementation is not only concerned with developers' ideas but also with consumers' choices. Information on the web relies on both user groups.

In a global context, most interfaces do not promote effective usage due to use of inappropriate metaphors in a global context. Many of the icons, metaphors, shapes, colors of text and background, frame/text locations on screen, etc. employed in systems design are relevant to the culture of origin of the software. Most of these applications are directly translated into different languages at most and distributed to users internationally.

In an international context, the graphic features employed in interface development makes a somewhat lesser impact in the variety of contexts it is concerned with, although it will be very clear to a minor proportion of the population as a whole. This provides an indication that consideration of human factors in the design of user interface for an international user base is an important factor in promoting effective usage of information systems. (Johnston & Johal, 1999; Corbitt & Thanasankit,2001).

User Interface Design Tools

Here is a list of free online design tools for fonts, patterns, logos, images, website design, team collaboration, and design inspiration.

- **Adobe Color:** Adobe Color lets you create color palettes using a handy color wheel. Set the base color and get the four complementary hues. Save your five-color palettes, or explore and edit other popular themes. Use the mobile app to create color schemes from real life images.
- **Pictaculous:** Pictaculous is a color palette generator. Use it to create a color palette from an image. Upload an image with your primary colors, and quickly receive a palette of complementary colors for your theme.
- **Colordot:** Colordot is a handy tool to identify and save colors. Just move your mouse to change colors, click to save. Colordot also has useful mobile app to create and share color palettes.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Google Fonts:** Google Fonts makes it quick and easy for everyone to use web fonts, including professional designers and developers. All of the fonts are open source. Customize them for your own use, or collaborate with the original designer to improve them.
- **Font Squirrel:** Font Squirrel is a website for free, high-quality, designer-friendly, commercial-use fonts. View font lists that are recently added and most downloaded.
- **Fontello:** Fontello is a tool to pack vector images into web fonts. It builds everything necessary to include graphics into your web pages. Also, Fontello has a big built-in collection of open source artworks.
- **Typecast:** Typecast is a tool to design a working prototype using simple visual controls, then export production-ready HTML and CSS or share by URL. Build common HTML elements like headings, paragraph text, block quotes, and lists. Focus on the finer points: precise control over your typography.
- **Modular Scale:** Modular Scale is a tool to help web designers size their type in a more meaningful way. Use the base and ratio controls to adjust a spectrum of typography.
- **Patternizer:** Patternizer is a tool to design your own patterns or browse free featured patterns. Patterns can be saved and shared with anyone, allowing for collaboration and remixing. Patternizer generates code that can be used with patternizer.js to create these patterns on any canvas element.
- **Subtle Patterns:** Subtle Patterns is another free pattern resource. Access over 400 free patterns to download. Sketch and Photoshop formats are ready to export for the web.
- **Freepik:** Freepik is a search engine of free vector designs, icons, and images. Freepik illustrations and graphic resources are selected by its design team to provide users with content that can be used in both personal and commercial projects.
- **Logopond:** Logopond is a website for logo design inspiration. Get ideas on your own logo direction, or find designers to tap.
- **Spaces Logo Maker:** This is a handy tool to easily make your own logo. Just type your brand name into the logo generator, choose a font, choose an icon, and experiment with different options. Spaces also has a variety of other useful generator tools for slogans, QR codes, image resizing, and more.
- **Dribble:** Dribbble is a website to discover, explore, and promote design. Web designers, graphic designers, illustrators, icon artists, typographers, logo designers, and other creative types share small screenshots that show their work, process, and current projects.
- **VSCO:** VSCO is a photo editing app to create, edit, and publish images from your smartphone. VSCO also has a community platform to promote and discover images.
- **Paper:** Paper is a useful free tool to create designs. Create sharp drawings and diagrams with Paper's sketch tools. Draw on photos or quickly spotlight details. Easily create notes — swipe right to create checklists, left to create titles.
- **Niice:** Niice is a website to gather, share, and discuss visual elements. Niice's drag-and-drop interface makes it easy to create boards for design collaboration.
- **Marvel:** Marvel is an app for design, prototyping, and collaboration. Create screens directly in Marvel, add images from Sketch or Photoshop, or sync designs from your cloud storage. Link all your designs together, then add gestures and transitions to make your prototype feel just like a real app or website.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Foundation:** Foundation is a responsive, front-end framework, with a collection of HTML, CSS, and JavaScript design patterns to build upon. Peruse its design gallery to see big brand websites built using Foundation.
- **Evernote:** Evernote is a useful tool to store, access, and share your design content. Snap a picture of a sketch or create a list or note. Keep your design images and plans synced across devices. Share ideas by collaborating seamlessly with your team in a group notebook.

Sample Applications

Vendio: Automated Selling on Amazon, EBay, and Facebook

With a focus on automation, Vendio ecommerce software saves you time with tools to easily put products on eBay, Amazon, Facebook and your own online Web store. List products once and they'll be published simultaneously on the supported marketplaces.

Other Vendio features include inventory control, sales and order management, email marketing, the shopping cart with drag-and-drop features and analytics reporting. Vendio Online Stores provides business owners with marketing features, including Google Analytics and built-in options, while a Vendio-powered Web store is optimized for mobile Apple iOS devices.

The KG TRAINS websites, powered by Vendio, offers a customized layout and a drag-and-drop to shopping cart feature for customers.

Intuit Ecommerce: The Merchant Account

Intuit's ecommerce offering offers a simple point and click interface that makes it easy to create and publish a store that you can update at any time.

With Intuit Websites, you'll get everything needed to design and launch an online store, including the domain name, hosting, the Simple Store ecommerce software, a site builder tool and online payments via Intuit merchant accounts. The merchant account is a big feature, as it enables small businesses to move beyond offering basic PayPal payments at checkout. Another nice feature of Intuit websites is the Facebook extension with which you can create a store a Facebook Business Page that automatically syncs with current store inventory.

Shopify: Advanced SEO and Analytics

Shopify hosted ecommerce lets you pick a template, optimize the design, add a product catalog, organize your products and create blog posts from a single administration dashboard. Shopify feature built-in mobile commerce that includes an iPhone app and mobile storefront. Marketing tools for SEO and coupon codes to help sell items are also available.

Shopify integrates with Google Analytics; this lets you automatically track customer purchases and shopping cart transactions connected to Google Analytics data. It also features built-in analytics to benchmark your online store's performance to help you track ecommerce over time.

The Shopify ecommerce platform powers The Artisan, a Philippine clothing brand that focuses on cut and sewn pieces.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

FINDINGS

E-commerce sector has huge growth potential and Internet is the back-bone of e-commerce. [2] mentioned All of total 120 sites sampled (100%) provided a set of global link to the site's first-level pages.

Global links to the first level were most positioned at the top of pages (78%), presented as navigation bar (40%), and tabs (23%), Global links were most commonly HTML no underlined (71%). Another common practice was text graphics (25%), which give designer greater control over the font type, size, and weight of the text. From 120 sites sample, one hundred and six sites (88%) provided return to home function. 93 sites (78%) provided an explicit link to home. This link mainly positioned at the top of the page (81 sites, 68%) and left side of the page (30 sites, 25%); including implicit home link Thirteen sites (11%) only provide company logo as a link to homepage. Nearly all company logo located in the top left corner of the page, only 3 sites that located its logo in the top right corner of the page. Whereas, 14 sites (12%) did not provide an explicit homepage View cart function provides information about items that have placed in the shopping cart by user. Only 25 sites from total sample that provide view cart function. The placement of this function varied, with the greatest number of sites placing it at the top right of main content area (13 sites, 46%) and on the left side (8 sites, 29%).

Manage account function enable user access information such as their email preferences, billing address, and shipping address. Nineteen sites (16%) provide manage account function. The placement of the page varied, but tended towards the top right area of the page (63%) or on the left side. Common labels used to represent this function were account and login. There were 13 sites used login (68%), whereas the rest sites used account as label.

Get help function provides answer to questions that frequently or may ask by user when they purchase items online. The objective is to help users without having to contact the merchant. This function (including contact us link) was most commonly located at the top of the page on the right side or on the left side.

The search function allows users to enter keyword into a test field and find information that matches the keyword entered. Forty-three sites (36%) provided a search function. Search function primarily found at the top of the page (51%) or on the left side of the page (37%). The rest sites positioned the search function at the main content area and on the right side. None of those sites presented this function with an icon.

Search function commonly presented as a text field labeled "Search" (68%), "Product search" (14%), "Product Find" (5%), and "Keyword Search" (12%). Most sites provided the search function as a text field and button (68%). Catalogue function makes it easy for users to see products. Seventy-two sites (60%) provided catalogue function. Catalogue function usually found at the top of main content area (72%) and on the left side (28%). This function most commonly labeled "Products"; other label includes catalogue, gallery, and collection. Personalization Function rarely provided by the 120 sites sample. Only 29 sites (24%) provided personalization function. Personalization function primarily found on the left side (59%). There were varied label used to representing this function.

Present Status

Many researchers have been using virtual reality (VR) in e-commerce to provide consumers with a new type of mediated experience—a virtual consumer experience. "A virtual consumer experience is a psychological and emotional state that consumers undergo when they interact with products in a 3D environment or within intelligent agents" (Hughes, Brusilovsky & Lewis, 2002). It has the potential to rich

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

consumers' experience (Hughes, Brusilovsky & Lewis, 2002). Hughes, Brusilovsky, and Lewis (2002) presented an adaptive navigation support system for using a virtual environment for online shopping, to help ease the consumer's navigation and to help the consumer focus on important product features. They used some detailed technologies-such as direct guidance, hiding, sorting, and annotation-for the adaptive navigation. Cássia, and Fernando [6] presented an adaptive 3D virtual environment with structure and content that changed according to the user's interest and preference and according to its application in e-commerce. They integrated intelligent agents, user models, and automatic content categorizations together in their system. Chittaro and Ranon (2000) presented two design guidelines (massive and walking product) to improve the usability of VR stores. In Sanna, Zunino, and Lamberti [11]'s presented VR e-commerce system which base on 5 Virtual Reality Modeling Language (VRML), an animated virtual human was introduced.

The virtual human was to be used as a virtual shopping assistant for helping online shoppers navigate through an e-commerce environment. Although prior studies show that VR can enhance e-commerce by providing virtual experiences and product interactions, VR technology can still only provide a virtual, not a real, experience. It is important to provide consumers with "real experiences" and "real object interactions".

Limitations

Non-Standard GUI Controls

Basic GUI widgets- command links and buttons, radio buttons and checkboxes, scrollbars, close boxes, and so on - are the lexical units that form dialog design's vocabulary. If you change the appearance or behavior of these units, it's like suddenly injecting foreign words into a natural-language communication.

Inconsistency

Non-standard GUI controls are a special case of the general problem of inconsistent design.

Confusion results when applications use different words or commands for the same thing, or when they use the same word for multiple concepts in different parts of the application.

Asking for the Same Info Twice

Users shouldn't have to enter the same information more than once.

No Default Values

Defaults help users in many ways. Most importantly, defaults can:

- Speed up the interaction by freeing users from having to specify a value if the default is acceptable;
- Teach, by example, the type of answer that is appropriate for the question; and
- Direct novice users toward a safe or common outcome, by letting them accept the default if they don't know what else to do.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

System-Centric Features

- Too many applications expose their dirty laundry, offering features that reflect the system's internal view of the data rather than users' understanding of the problem space.

Reset Button on Web Forms

- The reset button clears the user's entire input and returns the form to its pristine state. Users would want that only if they're repeatedly completing the same form with completely different data, which almost never happens on websites.

FUTURE ENHANCEMENTS

Future e-commerce technologies will definitely introduce more attractive and convenient tools for the customers, but some things remain constant – delivery times will improve, customer service will get increasingly better, and product selection will become ever greater. Graphical images are becoming more important in conveying meaning to a concept on the web sites rather than text. Moreover, graphical components are better suited to be used in certain ways to improve WBEC. Not surprisingly graphic images can also be used to attract customers and increase company's presence in the global e-market. Future - E Commerce have to be made very meaningful and smart, just displaying the product depending on category will not work, interface should be more interactive and need to ask relevant question on basis of their searching pattern or browsing pattern. Cross selling and up selling also need to be smarter.

Designers must start studying the trends of real people, the answers to real trends are those that must be implemented onto the user interface, the designer no longer have full control, the ball has turned and the users are the ones placing demands on how things are to be done. The future of e-commerce can be described simply by saying web mall, made possible by the use of portals. Although shopping on line by simply clicking a button is extreme convenience, users become more demanding as time passes and e-commerce becomes more and more popular. Virtual malls give the users the capability of searching for a wide range of products from a single location. This will eliminate the need to search with different search engines it will be much more like the popular phrase one-stop shopping.

Users are the driving forces of this technology as well as the largest impediment. Like all consumers the demands never seem to end. What seems to be yet another driving force of this technology is the way the users are expecting to view the products.

The success of e-commerce depends on the ability to attract non-computer-literate people to use them with ease. Much like driving a car or talking on the telephone, electronic commerce follows the same rules, the users do not care how the inner workings really work the end result is the important point. Electronic commerce will make significant advantages as long as the interface is kept simple and can be used in the same context a telephone is being used today.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Users Have Changed

For a long time, we've been using a traditional way of working with media. We have a desk, a computer and the keyboard and mouse as input-devices. We have accepted that the internet is an essential part of our lives and it has become nearly impossible to completely disconnect, even if we would like to.

In the past, in general we had a lot of control over our designs. There is a task and there is a consequence. Web design has become far more complex and it has become important to guide a user through one flow to optimize their user experience. We have to think of behaviour patterns, desired outcomes and potential mistakes the user can make. We're no longer developing a static experience; rather, we're creating living, interacting systems.

Users' behaviour online also has changed incredibly. Google, for example, has divided their users in three main categories:

1. The repetitive user: someone checking the same piece of information over and over again, such as e-mail or stock prices.
2. The bored user: someone who has time to kill.
3. The urgent user: a user with a request to find something specific and fast.

Your online habits make you a repetitive user on certain websites. Social media websites are great examples of this. The games you play online, or the news websites you check sometimes, are a result of you being a bored user. Finally, the urgent user is the target audience we often develop websites for during client work. They want information and they want it fast, such as the price of a product, a service they're specifically looking for, or the closest location of something they need now.

For designing the best user experience, it's always a good idea to keep these principles in mind. You should be able to tailor your website to make repetitive (predictable), bored and fast use as integrated as possible.

Graphical User Interface

The graphical user interface isn't exactly the future, rather it's a current way of designing interfaces. The idea of graphical user interfaces is that you complete visual tasks to receive results, such as clicking on a link to open a new page.

We guide our users through metaphors (such as the shopping cart icon) and standards we use in web design.

Natural User Interface

The natural user interface is the current Natural user interfaces focus more on doing. Users interact with the device or platform to achieve results, ideally enjoying the actual interaction as much as the accomplishment itself. Gestures especially (tools such as the Leap_Motion can play an important role in this) are important assets in natural user interfaces.

Existing examples include websites which have the functionality you can swipe (on tablets for example) to navigate through a gallery slider.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

A key element in natural user interface design is direct manipulation. Users love to have the feeling that they're directly engaging with a screen (use of gestures).

Organic User Interface

While we're still slowly moving from graphical user interfaces to natural user interfaces, a third spectacular evolution is on its way. Although it may take a while before we see and use it, it's closer than might seem at first sight. An organic user interface means that we manipulate the actual physical shape or position of a device to control it.

I'm referring in this case to bendable screens, and although this technology is very much in its infancy, it offers so many incredible opportunities to interact and navigate through devices.

Naturally, an organic user interface offers way more possibilities for input (and even output) than the previous interface concepts. At the moment we're used to point and click, though we're getting more involved with gestures, touch and (thanks to gyroscopes in devices) tilting and rotating, although it's still limited on the web. Eventually, we'll be bending, deforming and manipulating actual physical objects.

The future of e commerce [23] may be Personalization & Experience

Nearly all retail growth in the US at present is driven by ecommerce, and this looks set to continue in the years ahead as more people spend more money online. Greater personalization and a better customer experience will be the holy grail for ecommerce businesses in the future, as it becomes increasingly difficult to secure customers against a backdrop of ever increasing competition. Customers will eventually flock to those offering as close to the in-store experience as possible, and major ecommerce retailers are already striving to make things more personal and more tangible on web.

Delivery Drones

Perhaps one of the most exciting developments in ecommerce is one we are already starting to see in testing – drone delivery. Drones will in the future allow companies to deliver packages much more efficiently and quickly, with delivery times of just 60 or even 30 minutes from order entirely plausible. Drones will be sent out from distribution centres and travel directly to the delivery addresses provided, at significantly lower cost and logistical hassle than at present.

Curation and Pay Monthly Models

Product curation and pay monthly models are likely to continue to form an increasing part of the future of ecommerce. People don't want to buy generic products from you – Amazon is cheaper and quicker. But they do want to buy curated products, lifestyle products, and ecommerce packages where your product knowledge and expertise can create an altogether more enjoyable, rounded experience. Tracking Into Stores

The boundaries between ecommerce and physical commerce, i.e. the retail store, will become less definite as time passes, and companies are already looking at ways of tying together online tracking and customer information with their real-world experience. This also complements the idea of greater customisation of the shopping experience, allowing retailers to use existing online data to personalise their entire relationship – both online and offline.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Pop Up Shops

Customers are already shopping in new, alternative ways to before. "Showrooming" and "webrooming", where customers visit a local shop then buy online for a cheaper price, or vice versa, present new challenges for retailers, in bridging the gap between the online and offline.

Pop up shops can provide the answer, and can serve as a low-cost way of reaching out to new customers and winning new long-term fans. Pop up shops give customers a chance to connect with your brand in a physical way, while helping you reach corners of your market that might otherwise have been impossible for you through your online channels.

The future of ecommerce is ofcourse still unclear. But any prudent ecommerce business owner should take stock of what analysts are saying about the future direction of their industry, so they can be sure to capitalise on these new opportunities as they arise.

Artificial Intelligence Systems

Ecommerce already enjoys a significant advantage over other types of business, in the sense that there are thousands of high quality apps, all readily integrated into each other so that even small-budget players can rapidly automate the entirety of the process. At the same time, technologies rapidly change and improve, thanks to the strong competitive drive across the industry – after all, another retailer is only a click away.

The next step for ecommerce will be the application of AI systems, running evolutionary algorithms designed to find the absolute optimum.

The upshot for those running ecommerce businesses is to embrace these processes as soon as viable. Where the major players go, smaller retailers follow, and it won't be long before a proliferation of AI driven systems improves the capabilities of the ecommerce industry even further.

Measurement Across All Devices

Not everyone sticks to a single device when buying from you. In fact, more people are moving between devices, from the web to mobile to apps, before turning into paying customers. Measuring analytics across devices is still in its infancy, but it is becoming a more significant field of interest for those in ecommerce.

Once tracking of usage across multiple devices becomes more sophisticated, the processes of testing, tweaking and optimising the user experience still further can be set in motion. This will unlock even more value for ecommerce retailers, through providing further detailed insights into how the same people respond to their offering across platforms.

CONCLUSION

This chapter mainly focuses on web designers and their function appears to be shifting more towards the job of interface designers and information architects. With devices and their interfaces changing, so too will websites and their functionality. One requirement for e-commerce sites is that the contact numbers and addresses should always be displayed. Trust is essential for any type of commerce; trust mechanisms must be developed to give buyers, sellers, and intermediaries an accepted level of confidence of the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

system. The last thing a business wants is the consumer to think that they have something to hide. This chapter demonstrated various ways to design the interface and its features.

In summary a site within the e-commerce environment must always take the user into consideration first. According to Ron Scheer, in "Make your web site easy to use" designers must organize and be ready to reorganize, focused on the purposes and intentions. Always remember your brand, make things easy to find, make content easily understood, anticipate user interactions, if technology makes it possible help users decide what action to perform. When considering the navigation aspects of the site, make it as flat as possible. Make options mutually exclusive make sure the user realizes where the links take them. Create patterns that are easily remembered and make sure that the road from beginning to end does not seem tedious to the users. Designers are not done when the site is implemented and published, tests must be made, regular maintenance should be done to assure up to date content and simplicity. Although these are requirements they do not ensure that the site will be successful, nevertheless they are essential for the opportunity to survive

E-commerce is a new way of conducting, managing and executing business transactions using computer and telecommunications networks. As awareness of the Internet throughout the commercial world and general public increases, competitiveness will force lower entry barriers, continued rapid innovation and expansion of markets. The real key to making electronic commerce over the Internet a normal, everyday business activity is the convergence of the telecommunications, content/media and software industries. E-Commerce is expected to improve the productivity and competitiveness of participating businesses by unprecedented access to an on-line global market place with millions of customers and thousands of products and services.

Chapter 21
A Framework to Improve Performance of E-Commerce Websites

G. Sreedhar
Rashtriya Sanskrit Vidyapeetha (Deemed University), India

ABSTRACT

The growth of the world wide web has made business functions fast and easier. E-commerce has provided cost effective ways of doing business. E-commerce websites have the advantage of reaching a large number of customers regardless of distance and time limitations. The advantage of e-commerce over traditional businesses is faster speed and lower expenses for both businessmen and customers. The main objective of the chapter is to provide an efficient framework to analyse the performance of e-commerce websites and suggest the factors that need to be incorporated in e-commerce websites for better business intelligence. The purpose of business intelligence is to support better business decision making. In this chapter, a detailed description of business intelligence enables the web developer and end user to know the insights of e-commerce web applications. The methodology is comprehensive and it elaborates all aspects of the performance of a website.

INTRODUCTION

The World Wide Web (WWW) has become an important channel for information retrieval, electronic commerce and entertainment. However, long Web page download times have remained a major cause of frustration among Web users. According to the findings of the surveys conducted by Lightner et al, (1996) and the GVU (Graphic, Visualization and Usability) Centre at Georgia Institute of Technology (GVU, 1998), long download times have always been a major problem experienced by Web users. The survey by Pitkow et al, (1996) also indicates that the most widely cited problem using the WWW was that it took too long to download Web pages (i.e. 69% of respondents cited this problem). This problem is worsened by the exponential increase in the number of Web users over the years and the popularity of multimedia (e.g. video, voice) technology. This problem is so noticeable that Web users often equate

the "WWW" acronym with "World Wide Wait"! According to The long waiting time for downloading Web pages is often not tolerable even in the wired environment. Due to the increasing and excessive use of multimedia data (i.e. audio and video clips) on Web pages, this concern is continuously growing. The problem of 'long download time' is relevant not only to Web users but also to the authors and designers of websites, as websites that take a long time to download are rarely or less frequently visited (Reaux et al, 1997). The authors (G. Sreedhar et al, 2017) suggested in their research work slow Loading pages affects the sales and longer negative effect and 40% on line shoppers feel comfortable to revisit if the website load quickly.

Objectives

- To study and analyze the components of e-commerce application and relevance of web mining.
- To find insights of Business Intelligence.
- To incorporate the idea of Internet of Things.
- To provide a comprehensive frame work for analyzing the e-commerce website.
- To analyze the performance of e-commerce website through frame work.

BACKGROUND

E-Commerce Web Applications and Web Mining

E-commerce websites have the advantage of reaching a large number of customers regardless of distance and time limitations. The advantage of e-commerce over traditional businesses is the faster speed and the lower expenses for both e-commerce website owners and customers in completing customer transactions and orders. Because of the above advantages of e-commerce over traditional businesses, a lot of industries in different fields such as retailing, banking, medical services, transportation, communication, and education are establishing their business in the web. But creating a successful online business can be a very difficult and costly task if not taking into account e-commerce website design principles, web engineering techniques, and what e-commerce is supposed to do for the online business. Unfortunately, to most companies, web is nothing more than a place where transactions take place. All the e-commerce sites have high traffic. People surf the sites very often but the income is not always very high. So, the web data mining appeared and also nowadays much attention is paid to it. It is very important to apply web data mining to e-commerce in order to gather knowledge about users and rank data accordingly. It is advance successful technology through which information is filtered easier. So, web data mining became a publicly accessible source that gives promising results. With the use of e-commerce through internet, companies find a new and better way to do business. After developing the web site thought companies get benefits, they have to implement Web mining systems to understand their customers' profiles and to identify their own strength and weakness of their E-marketing efforts on the web through continuous improvements. Internet is a gold mine, but only for those companies who realize the importance of Web mining and adopt a Web mining strategy now. Web mining technology has many important roles that should be mentioned. It can automatically find, extract information from the variety web resources. The authors Etnoteam S. et al (2000) said that web mining develops, improves and enhances the quality and the efficiency of search engines, determines web pages or files,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

makes classifications. It can also generate large-scale real-time data. Web data mining discovers useful information from the Web hyperlink and page content. It has already changed the face of many business functions in a modern competitive enterprise. It is obviously easier to make right business decisions or understand the information that came from customers with the help of web data mining. It helps e-commerce to understand how to improve its services for special groups of customers and clients, and what tasks to realize. The e-commerce site can increase the exposure of its product pages and so average order size can be increased. Companies can save percentage of its budget per month owing to knowledge that was received from web mining analysis. Web data mining gathers implicit knowledge about clients and instructs e-commerce in every aspect. Then, it extracts valuable and comprehensible information from huge web resources to instruct e-commerce. It also gathers the information in an automated way and builds models used to predict customer purchasing decisions. Web mining is very precious to the company in the fields of understanding customer behaviour, improving customer services and relationship, launching target marketing campaigns, measuring the success of marketing efforts, and so on. Attractiveness of the site depends on its reasonable design of content and organizational structure. The author TIAN Meirong et al (2010) described that Web Mining can provide details of user behaviour, providing web site designers basis of decision making to improve the design of the site . E-Commerce generally refers to a new business model, where consumer makes online shopping, online transactions between merchants and online electronic payments and a variety of business activities, trading activities, financial activities and related integrated services activities, buyers and sellers are not met to conduct various business activities based on browser/server application mode.

Business Intelligence

The author Jayanthi Ranjan (2009) explained that the term Business Intelligence (BI) refers to technologies, applications and practices for the collection, integration, analysis, and presentation of business information. The purpose of Business Intelligence is to support better business decision making. Essentially, Business Intelligence systems are data-driven Decision Support Systems (DSS). Business Intelligence is sometimes used interchangeably with briefing books, report and query tools and executive information systems. Software elements support reporting, interactive "slice-and-dice" pivot-table analyses, visualization, and statistical data mining. Applications tackle sales, production, financial, and many other sources of business data for purposes that include business performance management. Information is often gathered about other companies in the same industry which is known as benchmarking. Common functions of business intelligence technologies include reporting, online analytical processing, analytics, data mining, process mining, complex event processing, business performance management, benchmarking, text mining, predictive analytics and prescriptive analytics. *Business intelligence* may be defined as a set of mathematical models and analysis methodologies that exploit the available data to generate information and knowledge useful for complex decision-making processes. Figure 1 illustrates the major benefits that a given organization may draw from the adoption of a business intelligence system. With the help of mathematical models and algorithms, it is actually possible to analyze a larger number of alternative actions, achieve more accurate conclusions and reach effective and timely decisions. The components of Business Intelligence are shown in Figure 2.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Benefits of business intelligence

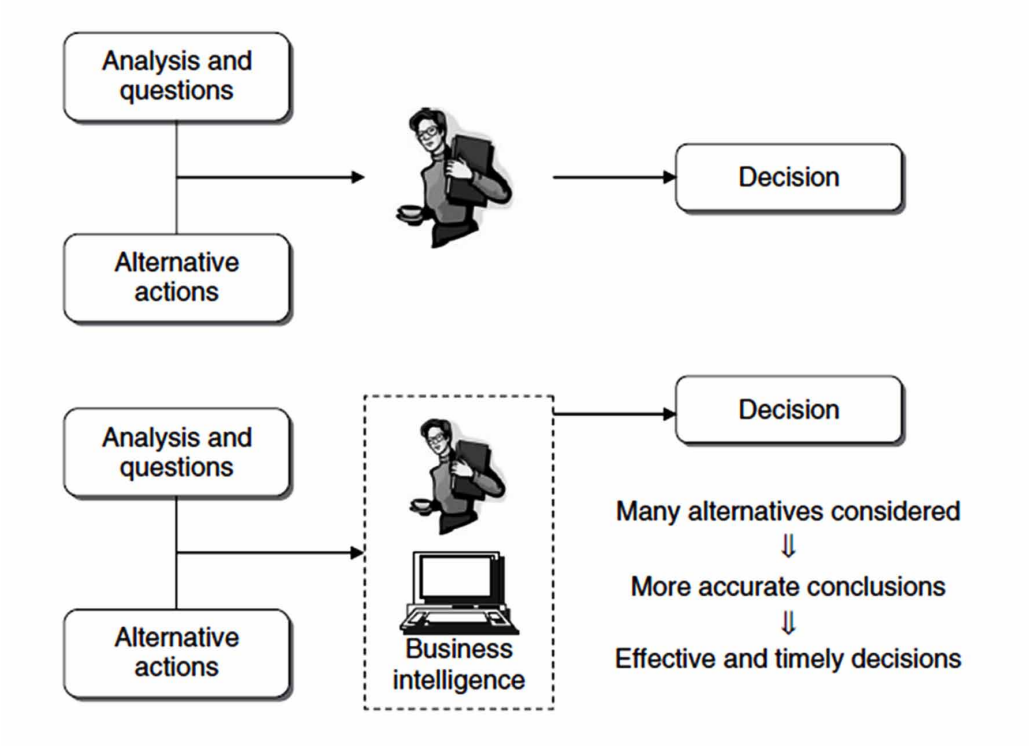

Figure 2. Business intelligence architecture

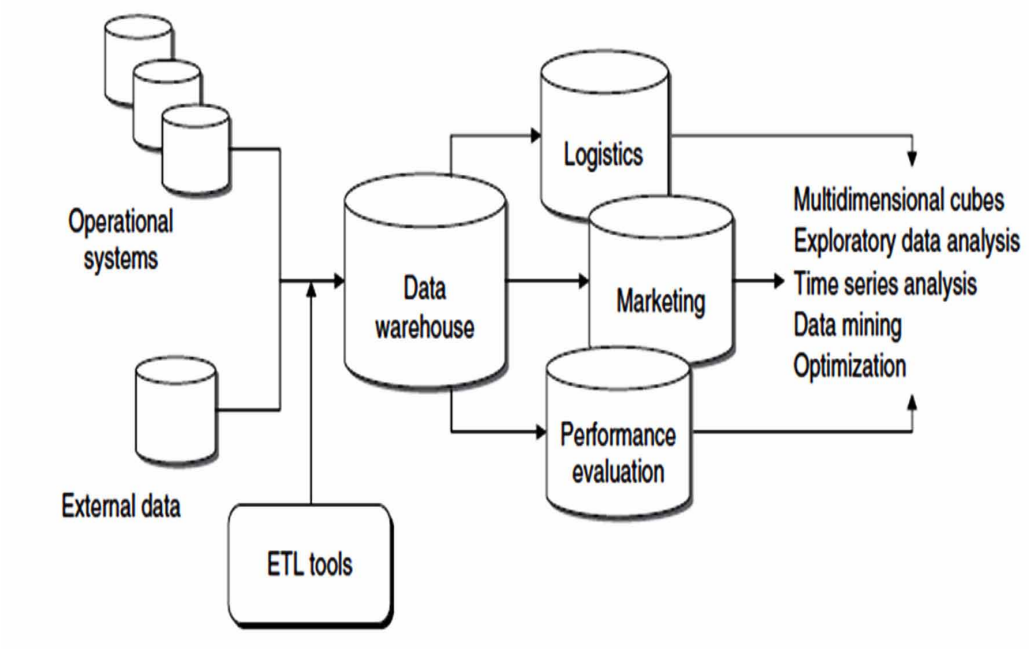


EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Data Warehouses and Data Marts

Using extraction and transformation tools known as *extract, transform, load* (ETL), the data originating from the different sources are stored in databases intended to support business intelligence analyses. These databases are usually referred to as *data warehouses* and *data marts*.

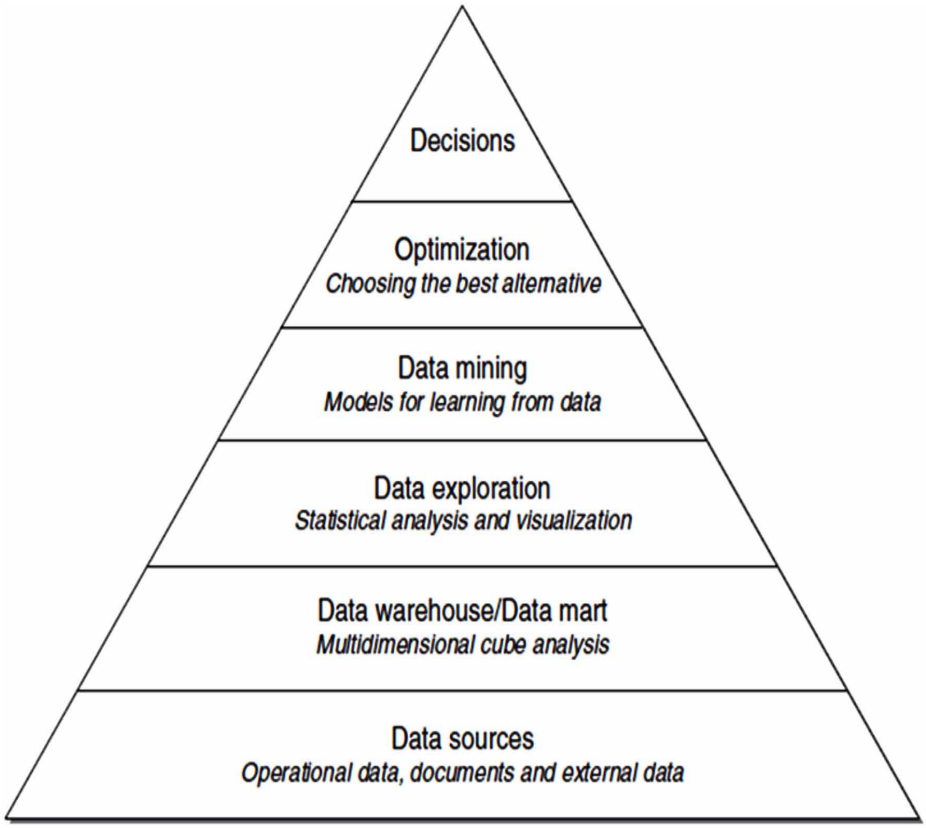
Business Intelligence Methodologies

Data are finally extracted and used to feed mathematical models and analysis methodologies intended to support decision makers. In a business intelligence system, several decision support applications may be implemented.

- Multidimensional cube analysis;
- Exploratory data analysis;
- Time series analysis;
- Inductive learning models for data mining;
- Optimization models.

The pyramid in Figure 3 shows the building blocks of a business intelligence system.

Figure 3. Pyramidical structure of business intelligence system



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Data Exploration

At the third level of the pyramid includes the tools for performing a *passive* business intelligence analysis, which consist of query and reporting systems, as well as statistical methods. These are referred to as passive methodologies because decision makers are requested to generate prior hypotheses or define data extraction criteria, and then use the analysis tools to find answers and confirm their original insight.

Data Mining

The fourth level includes *active* business intelligence methodologies, whose purpose is the extraction of information and knowledge from data. These include mathematical models for pattern recognition, machine learning and data mining techniques. Unlike the tools described at the previous level of the pyramid, the models of an active kind do not require decision makers to formulate any prior hypothesis to be later verified. Their purpose is instead to expand the decision makers' knowledge.

Optimization

The optimization level in the pyramid allow the user to determine the best solution out of a set of alternative actions.

Decisions

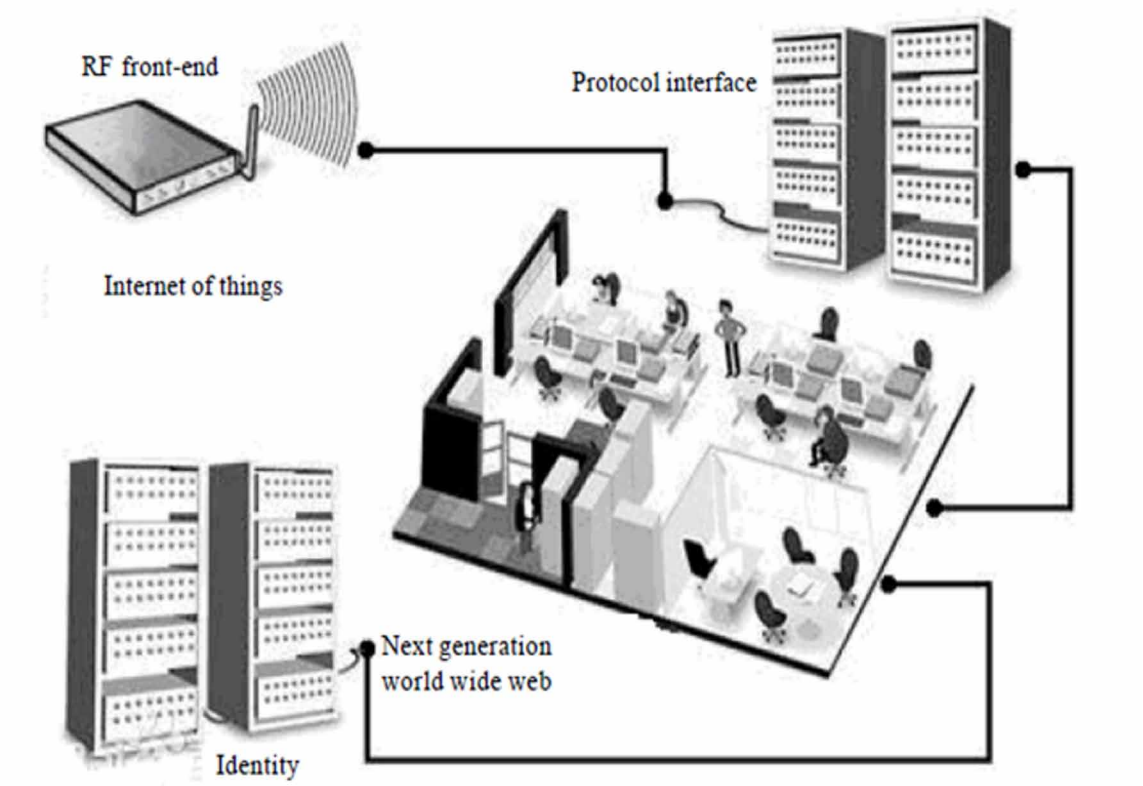
Finally, the top of the pyramid corresponds to the choice and the actual adoption of a specific decision and in some way represents the natural conclusion of the decision-making process. Even when business intelligence methodologies are available and successfully adopted, the choice of a decision pertains to the decision makers, who may also take advantage of informal and unstructured information available to adapt and modify the recommendations and the conclusions achieved through the use of mathematical models. The top of the pyramid supports advanced support tools of an active type. At the bottom, the required competencies are provided for the most part by the information systems specialists within the organization, usually referred to as *database administrators*. Analysts and experts in mathematical and statistical models are responsible for the intermediate phases. Finally, the activities of decision makers responsible for the application domain appear dominant at the top. As described above, business intelligence systems address the needs of different types of complex organizations, including agencies of public administration and associations.

Internet of Things (IoT)

The author G. Sreedhar (2017) in his book specified that Internet of Things (IoT) is a network which is composed with Radio Frequency Identification (RFID), infrared sensors, global positioning systems, laser scanners, gas sensors and other information sensing device, according to the agreed protocol, any goods is connected with the Internet for information exchange, communication, IoT is used to make intelligent identification, positioning, tracking, monitoring and management. The schematic diagram IoT is shown in the following Figure 4.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 4. Schematic structure of IoT



With the rapid development of e-commerce, its technology requirements will also increase on all aspects of future e-commerce. Firstly, the e-commerce applications are combined with IoT development and IoT technologies are applied in three important aspects of e-commerce, such as inventory, logistics and payment. An e-commerce system includes inventory, logistics, electronic payment and other important aspects, if IoT technology is used in various aspects of e-commerce, e-commerce will greatly improve the efficiency of the system. The diagram of E-Commerce with components of IoT is shown in the Figure 5.

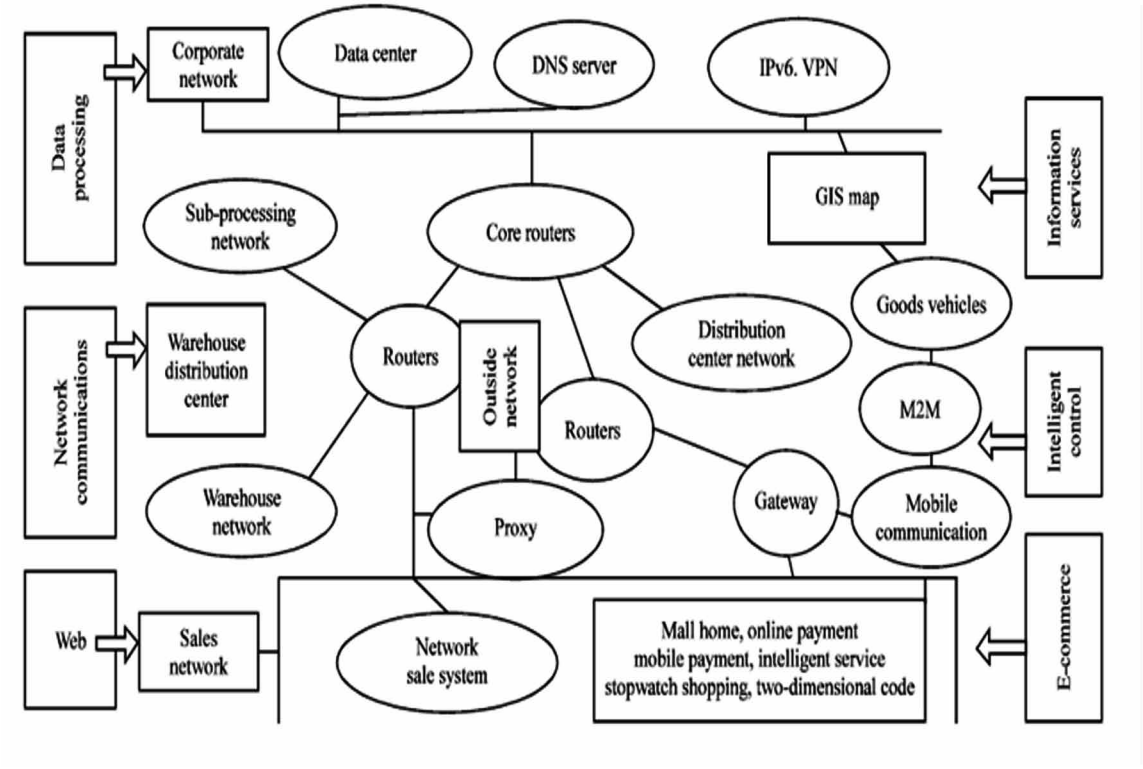
ANALYZING THE PERFORMANCE OF THE E-COMMERCE WEB APPLICATIONS

In order to improve the performance of the E-Commerce Web Applications, a well defined framework is needed. Following are various modules considered in analysing the performance of E-Commerce Web Applications

1. W3C Validation
2. Search Engine Optimization
3. Security
4. HTTP Compression
5. SURBL Check

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 5: Various components of Internet of Things



W3C Validation

Web standards are rules and guidelines established by the World Wide Web Consortium (W3C) developed to promote consistency in the design code which makes up a web page. Without getting technical, simply it's the guideline for the mark-up language which determines how a web page. Website Standards Association Inc. has been set up to identify the minimum website standards that websites should meet and educate internet users about how to get the most out of their websites. Web standards are the formal, non-proprietary standards and other technical specifications that define and describe aspects of the World Wide Web. The advantages in adhering to these standards are many:

- Web pages will display in a wide variety of browsers and computers, including new technology like iPhones, Droids, iPads, PDA devices, mobile phones, which greatly increases the viewing audience.
- W3C Standards promote the use of "Cascading Style Sheets" (CSS) or design code which is attached to the web page. rather than embedded in the page. The use of style sheets significantly reduces the page file size which means not only a faster page loading time but lower hosting costs for frequently visited sites due to using less bandwidth.
- Design features such as colors and fonts can be easily changed by just modifying one style sheet instead of editing every individual page in a web site, reducing the costs to modify your site.
- Search Engines are able to access and index pages designed to web standards with greater efficiency.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Search Engine Optimization

Search engine optimization (SEO) is the process of affecting the visibility of a website or a web page in a search engine's unpaid results, often referred to as natural, organic, or earned results. In general, the earlier (or higher ranked on the search results page), and more frequently a site appears in the search results list, the more visitors it will receive from the search engine's users. SEO may target different kinds of search, including image search, local search, video search, academic search, news search and industry-specific vertical search engines.

Security

Security is not an easy thing that you only need to implement or apply. The authors Steve Petite (2002) and Butler W. Lampson (2004) discussed in their research that the cost of securing small static web sites for some organizations could be larger than the organization could pay or think to pay. This high cost came from that you do not only need to protect the customer data but also you need to protect your systems from frequent attacks which may cause to Denial of service attack, that make your web site down. The author Sean-Philip Oriyano (2009) discussed in his research that attacks can prevent some organizations that depend on e-business or e-commerce from doing their Job. Therefore, most of the companies' web applications are likely to be under the risk of attacks. In order to protect these web applications, Sergey Gordeychik (2007) suggested that security experts must have the ability to detect the security threats and the back doors in their web application. After that, they can provide the solution starting with the urgent and highest priority problems such as Denial of service until covering all the security threats according to Caleb Sima (2004). Following protection techniques are suggested by majority authors like Craig Hinley et al (2015) to secure internet and web applications. They are as follows.

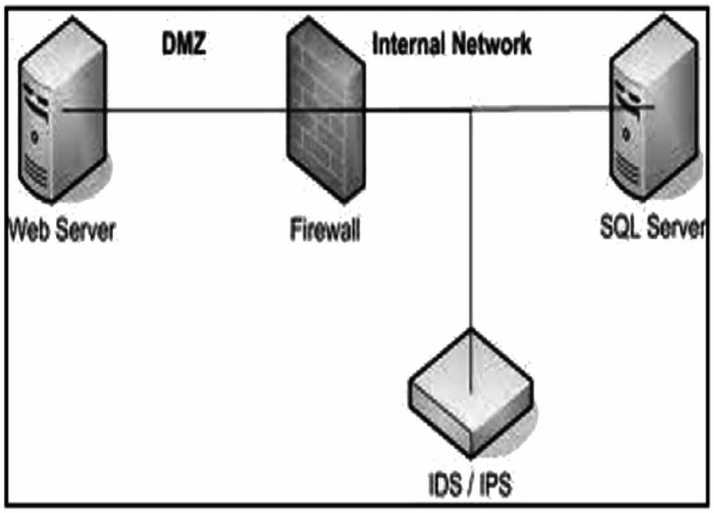
- **Intrusion Detection System (IDS):** The Intrusion Detection System (IDS) is used to detect many kinds of attacks behaviour that can compromise the security of the web application system. The author Fernando Esponda (2009) described in his research, these kinds of attacks that can be detected by the IDS include Worms, Viruses, unauthorized logins, access to sensitive files and folders, increase access privileges.
- **Intrusion Prevention System (IPS):** Another automated protection tools is called the Intrusion Prevention System (IPS). The authors Phurivit Sangkatsanee & Chalermpol Charnsripinyo (2011) explained in their research, IPS is usually a device that monitors the network in order to study the behaviour of the authorized user in the network. Therefore, the IPS will prevent unauthorized users from access the web application and the network resources.
- **Passwords:** The passwords strength of security is depending on the users who create them and the combination of characters, letters and numbers. Generally, the easiest method to access a password of web application defences is with inside knowledge. The authors Beate Grawemeyer & Hilary Johnson (2011) explained in their research, the attacker may track someone profile of social web site in order to get information about him to guess his organization web application password. Nowadays, most of the web application that server clients try to show the clients the complexity level of their password when creating their accounts or after that. Other web application also choose a default random password that is very complex and hard to remember from the users

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

themselves, which make them write it down anywhere cause another threat possibility. Password itself cannot be the only protection technique that a company uses.

- **SSL and Data Encryption:** The authors Xiaowei Li and Yuan Xue (2011) explains that Socket Secure Layer (SSL) protocol and data encryption may secure the customer data during the transmission of these data from the web server to the client machine. The authors Kyu Ho Park and Ki-Woong Park (2011) described in their research the server and the client system need to decrypt these data once they want to read it or modify it. Data encryption same as password cannot be work alone without other protection technique. Usually this encryption and decryption are based on shared key that both the client and the server need to know. Therefore, distribution of this shared key should be also run through a secure process.
- **Firewalls:** As shown in Figure 6 the firewall is like a barrier inside the network to allow only the people who have authorized access to pass through this gate. Firewall can be either hardware device or software tool that can be configured to allow and block certain users, packets, ports, or even Internet Addresses (IPs). The authors Peder Jungck and Simon S.Y Shim (2004) and Alex X. Liu (2012) discussed in their research, the attacker may make a huge process in order to convince the firewall that he is an authorized user to pass through it and this is what usually happens in the Trojan horse virus. In the computer networks, a firewall is working with a router. The firewall scans each network packet to decide whether to forward it toward its destination inside my company network or forbidden its pass. A firewall also includes or works with a proxy server that creates network requests on behalf of the users systems. A firewall is often installed in a specially designated computer separate from the rest of the network so that not any arrived packet can get directly at the servers system in the company network.

Figure 6. Schematic diagram of firewall



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Standard Scanning Programs:** The known attacks and security threats are stored in automated tools to scan all the programs and packet sent or received on the clients system. Most of these automated scanners protect the organizations network from known attacks made before on hardware devices and software. Most of these scanners secure your systems from fixed list of threats. Therefore, there is no guarantee to protect your applications and systems from new expected kind of attacks that did not happen before. Sometimes they can alert them users that doing some actions or accessing some file will be vulnerable and security risk. Usually these applications require daily update for its libraries in order to update the list of threats to include the new threats according the authors Marjan Korosec & Joze Duhovnik (2010) that just happen to other computer systems.
- **Internet Service Provider:** Most of the protection techniques are mainly to guarantee securing the systems and data inside an organization. However, what about the internet service providers (ISPs). Most of the ISPs do not care about security same as the application productions companies. Security is not their business. Nevertheless, nowadays most of these third parties start looking for security improvements in order to enhance or keep their reputation in the IT markets as specified by authors Serguei Netessine and Nils Rudi (2006).
- **Code Implementation:** Programmers are not security experts that why they do not consider that much the security threats while developing an application. Some huge development companies apply security testing for their applications after the development phase. While the most of these companies only deals with security after their applications face an attack. However, in order to protect your system you should not only test the code but you need to implement all the validation and verification required in the code development phase. In addition, to secure all the servers and databases that is worked in the background of these applications. Tester mainly are not attacker that why he cannot imagine the complete way of attacking the system. Therefore, the authors Lingli Zhang and Chandra Krintz (2005) and Mu-Woong Lee and Sunghun Kim (2011) suggested that companies should start looking for hiring attacker in their quality assurance departments.

HTTP Compression

HTTP compression is a capability that can be built into web servers and web clients to improve transfer speed and bandwidth utilization. HTTP data is compressed before it is sent from the server: compliant browsers will announce what methods are supported to the server before downloading the correct format; browsers that do not support compliant compression method will download uncompressed data. There are two different ways compression can be done in HTTP. At a lower level, a Transfer-Encoding header field may indicate the payload of a HTTP message is compressed. At a higher level, a Content-Encoding header field may indicate that a resource being transferred, cached, or otherwise referenced is compressed. Compression using Content-Encoding is more widely supported than Transfer-Encoding, and some browsers do not advertise support for Transfer-Encoding compression to avoid triggering bugs in servers.

SURBL Database Check

SURBLs are lists of *web sites* that have appeared in unsolicited messages. Sender lists can be used in a first stage filter to help identify 80% to 90% of unsolicited messages. SURBLs can help find about 75% of the otherwise difficult, remaining unsolicited messages in a second stage filter. Used together with sender lists, SURBLs have proven to be a highly-effective way to detect 95% of unsolicited messages.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Using SURBLs requires a mail filter that can extract web sites from message bodies and check them against the lists.

IMPLEMENTATION

In order to suggest the status of e-commerce web applications for better business intelligence a web program is developed with the standard tool known as *webcheckme*. The web program accepts the URL of e-commerce website and verifies all the aspects of as mentioned in above section. The web program produces the status of e-commerce website in 10-point scale. The web developer of e-commerce website can improve the performance of website based on the value of 10-point scale and comments. A case study was conducted on some of the popular e-commerce websites and the following table lists these websites.

Table 1. List of e-commerce websites

S.No	E-Commerce Website
1	www.shopclues.com
2	www.paytm.com
3	www.snapdeal.com
4	www.shopbychoice.com
5	www.ebay.com
6	www.irctc.co.in
7	www.flipkart.com
8	www.amazon.com
9	www.zapstore.com
10	www.homeshop18.com

The analysis of web program is shown in Figure 7.

The results of web program on 10 e-commerce websites with 10-point score value are shown in Table 2 and snapshot of 10 e-commerce websites' scores are shown in Figure 8.

CONCLUSION

The chapter identifies the various factors that need to be consider the in analyzing the performance of e-commerce website. The methodology is very much comprehensive and well applicable to e-commerce web application product because web application is the integration of number of different components. In this chapter, a significant effort is made to evaluate status of e-commerce website. The chapter has shown the path and cautiousness to be adopted in web design process for the web designers for better service to the end users. The importance of the quality of Web Design is essential in the light of enormous growth of web applications. In this connection the theme of the chapter shows a direction to improve

Chapter 22
Creating Utilitarian and Hedonic Value from Website Quality and Online Retail Performance

Edward Shih-Tse Wang
National Chung Hsing University, Taichung, Taiwan

ABSTRACT

Although consumer-perceived utilitarian value and hedonic value have been considered essential antecedents of consumer behavior, few studies have investigated the effects of both website quality and online retail performance on consumer-perceived utilitarian value and hedonic value, which in turn affect consumers' relationship commitment. This study analyzed data from 394 online shoppers using structural equation modeling. The results revealed that both utilitarian and hedonic value significantly and positively affected relationship commitment. Information quality, system quality, service quality, and price fairness were revealed to significantly and positively affect the perceived utilitarian value of online stores, whereas system and service quality increased perceived hedonic value.

INTRODUCTION

Because the Internet is a popular shopping medium for consumers worldwide (Chen et al., 2013), retailers are increasingly shifting the focus of their business online. The Internet is thus continually transforming the retail sector (Blázquez, 2014). The number of online stores has grown considerably in the previous few years and the retail environment is increasingly competitive. Ensuring repeated visits from online shoppers and building store loyalty are some of the crucial challenges for online retailers. Consumers' perceived value plays a dominant role in the adoption of technology (Yang et al., 2012) and has received substantial attention in the marketing literature (Iniesta-Bonillo et al., 2012) because consumers' value judgments affect their satisfaction, preference, and loyalty levels (Overby and Lee, 2006). Therefore, online store managers have responded to these challenges by creating value in their online store.

Studies have considered two types of consumers' perceived value in an online shopping environment: utilitarian and hedonic value (Blázquez, 2014). Perceived utilitarian value is related to consumers' overall

assessment of a purchase—whether it fulfils their needs from a functional perspective—and perceived hedonic value is related to a product's entertainment-related and emotional benefits (Chang and Tseng, 2013). One study emphasized that online vendors should consider whether their website provides adequate utilitarian and hedonic value to consumers during the website's development (Chiu et al., 2009). Many studies have confirmed that perceived utilitarian and hedonic value affects consumers' online shopping satisfaction (Yang and Wu, 2009), attitude toward a website (Chiagouris and Ray, 2010), preference (Overby and Lee, 2006), loyalty (Hung et al., 2010; Chen et al., 2013), online repurchase intention (Chang and Tseng, 2013), mobile Internet use intention (Yang et al., 2012), and Web 2.0 contribution behavior (Hung et al., 2010).

Several studies on online consumers have further explored the antecedent variables of utilitarian and hedonic value because of their demonstrated importance. Studies have revealed that consumers' perceived utilitarian and hedonic value was affected by an e-store's image (Chang and Tseng, 2013), the environmental attributes of the website (Charfi and Lombardot, 2015), e-service quality (Chen et al., 2013), novelty, flow, efficiency, and complementarities (Hung et al., 2010). In addition, recent research has investigated the effects of website quality dimensions (i.e., information, system, and service) on consumer-perceived utilitarian and hedonic value; the results revealed that system and service quality affected utilitarian shopping value, whereas information and service quality affected hedonic shopping value (Kim et al., 2012). The limitations of the study were that exogenous variables accounted for only 20.2% of the variance in hedonic value and 21.6% of the variance in utilitarian value; consequently, the authors suggested that other factors might have also affected the consumers' perceptions of hedonic and utilitarian value. A clearer explanation of consumers' perceptions can be provided by an integrated model that combines different perspectives than a model with a single perspective (Shih and Chen, 2013).

Service quality, product quality, and price fairness have been revealed as the three key retail performance factors affecting consumers' online shopping experience (Kim et al., 2008) and online shopping experiences were demonstrated to produce utilitarian and hedonic value (Blázquez, 2014). The three key factors have been investigated for their direct effect on consumer satisfaction (Yieh et al., Chiu, 2007), transaction risk perceptions (Wang and Tsai, 2014), and retailer trust and loyalty (Yieh et al., 2007) in the context of bricks and mortar shops. Although researchers have asserted that website quality (Kim et al., 2012) and online retail performance (Kim et al., 2008) affect consumer-perceived product value, how the factors of website quality and online retail performance relate to specific value perceptions (i.e., perceived utilitarian and hedonic value) remains unclear.

HYPOTHESES DEVELOPMENT

Information quality refers to the completeness, detail, accuracy, timeliness, and reliability of information provided to customers (Ahn et al., 2003). Perceived utilitarian value is consumers' overall assessment of whether an online shopping experience successfully enabled them to complete their shopping tasks and goals (Dubelaar et al., 2003). Goetzinger et al. (2003) suggested that online consumers' concern about the quality of information available online after having previously received incorrect information can result in their not taking advantage of beneficial product offerings. Thus, high-quality product and service information enables online consumers to make superior purchasing decisions (Fang et al., 2011). Because higher quality information leads to superior buying decisions, researchers have indicated that

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

information currency is strongly associated with utilitarian shopping value (Kim et al., 2012). Thus, the following hypothesis was proposed:

H1: The consumer-perceived information quality of an online store positively affects its consumer-perceived utilitarian value.

System quality refers to consumers' overall assessment of the performance of an online store regarding information delivery, response time, and retrieval (Chompis et al., 2014). It represents the functionality of an online store and is assessed according to factors such as the ease of navigation, response speed, and security and accuracy of transactions (Ahn et al., 2003). DeLone and McLean (2003) suggested that accessibility, availability, and reliability are the system quality factors most demanded by users. Previous research has further indicated that system connection stability is positively associated with utilitarian value (Park et al., 2011). Because system quality entails efficiency from an engineering perspective, researchers have additionally suggested that consumers' efficiency perceptions positively affect their utilitarian value perceptions toward a website (Hung et al., 2010). Therefore, the following hypothesis was proposed:

H2: The consumer-perceived system quality of an online store positively affects its consumer-perceived utilitarian value.

Perceived hedonic value is defined as consumers' overall evaluation of whether the online shopping experience is psychologically and emotionally worthwhile (Park et al., 2011). System quality is defined as customers' perceptions of a system's performance from the perspective of effective technological properties, with higher system quality rendering interactions with the system smoother (Chompis et al., 2014). Because accessibility strongly affects online consumers' enthusiasm and online consumers are generally impatient while waiting for data access, the accessibility of websites affects hedonic shopping value (Kim et al., 2012). Therefore, the following hypothesis was proposed:

H3: The consumer-perceived system quality of an online store positively affects its consumer-perceived hedonic value.

Perceived service quality is defined as consumers' evaluation of service received according to service performance standards (Jiang and Wang, 2006) and based on a service that facilitated achieving their shopping objectives (Michon et al., 2015). Evaluating utilitarian value is based on the assessment of the instrumental or functional utility of the service provided (Petruzzellis, 2010). Previous research has suggested that efficient and timely service delivery affects consumer-perceived utilitarian value (Kleijnen et al., 2007). Although perceived service quality was positively associated with perceived value (Kim et al., 2008), some studies have indicated that consumers' service quality perceptions significantly affect their assessments of utilitarian value (Mouakket, 2014). Thus, the following hypothesis was proposed:

H4: Consumers' perceived service quality of an online store positively affects their perceived utilitarian value of the online store.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Perceived hedonic value is the perceived fun or pleasure obtained while using a product or service (Song et al., 2012) and represents the overall emotional feeling induced and imagery used by the service (Kim et al., 2012). Consumers' perceived hedonic value is their overall assessment of whether using the product or service is enjoyable (Park et al., 2011). Perceived service quality is consumers' overall assessment of the excellence and quality of their shopping experience (Kim et al., 2008), and shopping experiences in the servicescape evoke consumers' emotions (Wu et al., 2015). Thus, service quality may elicit positive consumer emotions, enhance their shopping enjoyment, and prompt positive hedonic shopping benefits (Michon et al., 2015). Service quality perceptions positively affect perceived hedonic value (Babin et al., 2005). Accordingly, the following hypothesis is proposed.

H5: Consumers' perceived service quality of an online store positively affects their perceived hedonic value of the online store.

Utilitarian value is the ability of a product to perform its intended functions for consumers (Kim et al., 2012). In addition, it refers to consumers' cognitive and logical assessment of the product or service performance and functionality (Rauniar et al., 2014) from the perspective of instrumental and functional benefits (Collier et al., 2014). Thus, consumers' perceived utilitarian value relates to their overall evaluation of product or service features (Lee and Overby, 2004) and whether the outcome of the product's or service's use completely fulfils the product or service goal-directed performance (Park et al., 2011). Consumers form opinions of utilitarian value after evaluating product performance parameters such as quality (Pant et al., 2011). Chandon et al. (2000) suggested that utilitarian value is associated with the benefits of product quality. Thus, online shoppers may form opinions of utilitarian value based on whether the online store delivers the promised product quality. Based on these findings, the following hypothesis was proposed:

H6: Consumers' perceived product quality of an online store positively affects their perceived utilitarian value of the online store.

Price has been emphasized as a crucial factor in consumers' perceived value because price savings add the dimension of economic value (Lee and Overby, 2004). Less financial resources are required to fulfil a given need (Sindhav and Adidam, 2012), and consumers usually attempt to find the desired product at a reasonable price. Pant et al. (2011) asserted that utilitarian value can generally be stated in terms of price and cost saving. When consumers find an excellent price or deal, their utilitarian value is satisfied (Sindhav and Adidam, 2012). Thus, consumers may derive utilitarian value by perceiving the price fairness of the product offered.

H7: Consumers' perceived price fairness of an online store positively affects their perceived utilitarian value of the online store.

Consumers' perceived value of a certain service is their primary motivation for using the service (Yang and Lee, 2010). Utilitarian and hedonic value has been proposed as a determinant of brand commitment (Chaudhuri and Holbrook, 2002) and e-shopper commitment (Bilgihan et al., 2013). Therefore, the following hypotheses were proposed:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

H8: Consumers' perceived utilitarian value of an online store positively affects their commitment to the online store.
H9: Consumers' perceived hedonic value of an online store positively affects their commitment to the online store.

The hypothesized model contained three control variables because of their potential effect on consumers' service evaluations: age, gender, and purchase frequency (Scarpi, 2006; Mishra and Srivastava, 2011; Jeannot et al., 2013).

METHOD

Data Collection

Data were collected at the train station of Taichung, a city in the center of Taiwan. The train station was chosen because it is the most important public area in the city and is open for all to enter. Trained interviewers conducted a field survey. Passers-by and passengers at the train station who were existing members of a shopping website were requested to participate. If the passers-by and passengers accepted the invitation, they were administered the one-page questionnaire. A prompter instructed participants to consider their 'currently most-visited online store.' Subsequently, each participant rated their perceptions and attitudes toward the store in terms of information quality, system quality, service quality, product quality, price fairness, utilitarian and hedonic value perceptions, and attitude toward relationship commitment. Although no incentives were offered, 394 online store members voluntarily participated. The survey sample comprised more females than males (70.6% vs. 29.4%). The under-20 age group (47.7%) was the most populous, followed by the 20–29 (43.7%) and 30–39 (6.9%) age groups. Additionally, participants who generally visited the online store in question less than 6 times a year formed the majority (71.3%), followed by those who visited the website 6–10 times (17.0%) and 11–15 times a year (6.1%).

Measures

All measures used were determined using multi-item scales adapted from previous studies. The two 7-item scales designed by Ahn et al. (2003) were employed to measure information quality and system quality. Service and product quality constructs were measured using the 6- and 3-item scales, respectively, developed by Ahn et al. (2004). Price fairness was measured using a 3-item scale (Wang and Tsai, 2014). Utilitarian and hedonic value were measured using two 4-item scales adapted from Paridon et al. (2006). Relationship commitment was measured using a 5-item scale adapted from Holloway et al. (2009).

ANALYSIS AND RESULTS

Measurement Accuracy Analysis

Table 1 presents the descriptive statistics of the research construct measures including individual mean score, standard deviation, and square root of average variance extracted (AVE, on the diagonal) for each

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Correlation between research constructs

Research Constructs	Mean	S.D.	Correlation							
			InfQ	SysQ	SerQ	ProQ	PF	UV	HV	RC
Perceived information quality (InfQ)	4.95	0.98	0.84							
Perceived system fairness(SysQ)	5.05	0.95	0.71	0.76						
Perceived service quality (SerQ)	4.65	0.98	0.67	0.64	0.76					
Perceived product quality (ProQ)	4.91	0.95	0.59	0.62	0.51	0.63				
Perceived price fairness(PF)	5.02	1.06	0.51	0.57	0.43	0.55	0.89			
Perceived utilitarian value (UV)	5.18	1.01	0.68	0.70	0.58	0.54	0.52	0.85		
Perceived hedonic value (HV)	4.98	1.14	0.52	0.54	0.55	0.39	0.39	0.61	0.88	
Relationship commitment(RC)	4.90	1.08	0.58	0.60	0.59	0.42	0.46	0.62	0.72	0.82

Note: The square root of AVE for each construct is placed on the diagonal.
Scores: 1 – strongly disagree; 4 – neutral; 7 – strongly agree.

construct and any correlations between the measures. This study evaluated the research framework through structural equation modeling (SEM). For assessing the reliability and convergent validity of the scale items, confirmatory factor analysis (CFA) of the 39 items was conducted. The study used composite reliability (CR) and AVE for evaluating reliability and discriminants. The CFA results of CR and AVE are listed in Table 2. CR $\geq$ 0.6 indicated favorable consistency (Santos-Vijande et al., 2012). All CR exceeded this threshold level; thus, the scale items were reliable. To ensure discriminant validity, the square root of each construct's AVE should exceed its factors of correlation with other constructs (Zhu and Chen, 2012), and Table 1 confirms that this was the case.

Model-Fit Assessment

The model was tested using the linear structural relationships model (LISREL) 8.7 for SEM. The ratio of χ^2 to degrees of freedom (2.68) was less than the cutoff value (5.0), indicating an acceptable fit (Zain et al., 2013). The normed fit index, nonnormed fit index, comparative fit index, incremental fit index, and relative fit index were 0.97, 0.98, 0.98, 0.98, and 0.96, respectively. All these indexes were higher than the minimum value of 0.90 suggested by Hair et al. (1998). The goodness-of-fit index was 0.79, near the cutoff value of 0.80 (Teh and Yong, 2011). Moreover, the root-mean-square error of approximation (0.065) was less than 0.08, indicating an adequate fit (Zain et al., 2013). In summary, all of the indexes matched or were near the recommended values, indicating that the fitness of the model was acceptable.

Results of Hypotheses Testing

SEM using LISREL 8.7 was employed for assessing the hypothesized model, and the results are presented in Figure 1. H1 predicted that information quality has a positive relationship with the perceived utilitarian value of an online store. The results indicate an insignificant relationship ($\gamma_{11} = .23$, $p < .001$). Hypotheses 2–5 predicted the positive effect of system and service quality on the perceived utilitarian value and hedonic value of an online store. These hypotheses were supported, indicating that both system and service quality positively affect utilitarian value and hedonic value (H2: $\gamma_{12} = .43$, $p < .001$; H3:

Table 2. CFA results of the research construct scales

Research Constructs	Measurement Items	C.R	AVE
Perceived information quality (InfQ)	The online store has sufficient contents which I expect to find	.95	.71
	The online store provides complete information		
	The online store provides detailed information		
	The online store provides accurate information		
	The online store provides timely information		
	The online store provides reliable information		
	The online store communicates information in an appropriate format		
Perceived system quality (SysQ)	The online store has an appropriate style of design for business type	.90	.57
	The online store has an easy navigation to information		
	The online store has fast response and transaction processing		
	The online store keeps transactions secure from exposure		
	I can use the online store when I want to use it		
	The online store has a good functionality relevant to site type		
	The online store keeps error-free transactions		
Perceived service quality (SerQ)	The online store service provider anticipates and responds promptly to user request	.89	.57
	The online store service provider can be depended on to provide whatever is promised		
	The online store service provider instills confidence in users and reduces uncertainty		
	The online store service provider understands and adapts to the user's specific needs		
	The online store service provider provides follow-up service to users		
	The online store service provider gives a professional and competence image		
Perceived Product quality (PQ)	The online store deals products with high quality	.66	.40
	The online store deals various products		
	The online store supports high product availability		
Perceived price fairness(PF)	The products sold on the online store are at a fair price	.92	.79
	The products price on the online store are reasonable		
	The products price on the online store are acceptable		
Perceived utilitarian value (UV)	The shopping trip on the online store was useful	.92	.73
	I was satisfied with the items I purchased from the online store		
	I accomplished just what I wanted to on the shopping trip on the online store		
	While shopping on the online store, I found just the item(s) I was looking for		
Perceived hedonic value (HV)	The shopping trip on the online store was truly a joy	.93	.78
	The shopping trip on the online store truly felt like an escape		
	I had a good time on the online store because I was able to act on the spur of the moment		
	I enjoyed the shopping trip on the online store for its own sake, not just for the items I may have purchased		
Relationship commitment(RC)	I care about the long-term success of this online store.	.91	.67
	I am a loyal customer of this online store		
	I am likely to grow fond of this online store		
	I believe I could develop a good relationship with this online store		
	I think I might become loyal to this online store

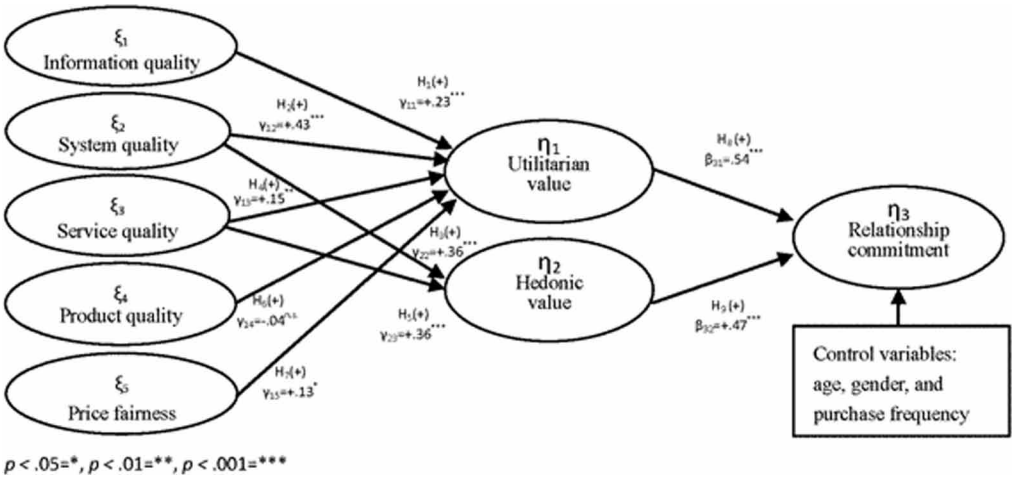
$\gamma_{22} = .36$, $p < .001$; H4: $\gamma_{13} = .15$, $p < .01$; H5: $\gamma_{23} = .36$, $p < .001$). H6 and H7 predicted that product quality and price fairness positively affect the perceived utilitarian value of an online store. The results reveal that price fairness is positively related to perceived utilitarian value (H7: $\gamma_{15} = .13$, $p < .05$); however, product quality was discovered to be unrelated to perceived utilitarian value (H6: $\gamma_{14} = -.04$, nonsignificant). Finally, H8 and H9 predicted that perceived utilitarian and hedonic value positive affect relationship commitment ($\beta_{31} = .54$, $p < .001$; $\beta_{32} = .47$, $p < .001$). Website quality dimensions and online retail performance factors were discovered to have considerable explanatory power as indicators of the utilitarian and hedonic value of an online store (squared multiple correlations of 64% and 44%, respectively), resulting in relationship commitment (squared multiple correlation of 61%).

Figure 1. Conceptual framework and research results



DISCUSSION

While delivering consumer value is an essential marketing and business concept, online marketers should develop a more comprehensive understanding of how consumer value can be delivered from different perspectives. This study investigated the effect of website quality and retail performance on creating consumer-perceived value, which in turn develops relationship commitment. The results demonstrated that the consumer-perceived utilitarian and hedonic value of a retail website determined consumers' relationship commitment. In particular, price fairness and three website quality dimensions (information quality, system quality, and service quality) were antecedent variables of the perceived utilitarian value of online stores, with the amount of explained variance being 62%. Additionally, system and service quality were revealed to affect the consumer-perceived hedonic value of online stores, with the explained variance of this relationship being 40%. Therefore, consumers' assessment of information quality, system quality, service quality, and price fairness positively affected consumers' perceived utilitarian value of online stores, whereas perceived system and service quality positively affected a store's perceived hedonic value. However, perceived product quality was discovered to be unrelated to the consumer-perceived hedonic value of online stores, perhaps because product quality is difficult to assess in the context of an online

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

store. The results indicated how the consumer-perceived utilitarian and hedonic value of an online store night be created from website quality and online retail performance perspectives.

Theoretical and Managerial Implications

Previous studies on online shopping have not explained whether website quality or online retail performance affect consumer-perceived utilitarian and hedonic value. Therefore, this study proposed an integrated model to determine the effect of website quality and online retail performance on consumer utilitarian and hedonic value perceptions and consumers' relationship commitment in the context of online stores. Consumer-perceived utilitarian value was positively affected by information, system, and service quality, whereas perceived hedonic value was positively affected by service quality, which was consistent with the results of Kim et al. (2012). Specifically, the study investigated the effect of information quality, system quality, service quality, product quality, and price fairness on utilitarian and hedonic value. Price factors were discovered to induce utilitarian value perceptions. Compared with Kim et al. (2012), the current study's explained variance regarding consumer-perceived utilitarian and hedonic value was substantially improved by introducing the online retail performance factors. Therefore, this study contributes to the literature an integrated approach for exploring how the consumer-perceived utilitarian and hedonic value of online stores can be created from website quality and retail performance perspectives. In summary, conducting integrated research on website quality, retail performance, and consumer-perceived value is crucial to building consumer-perceived value and constitutes a critical topic in marketing research.

Consumers' perceived utilitarian and hedonic value facilitated the building of consumer commitment to an online store. Therefore, online store managers should recognize the importance of building the consumers' perceived utilitarian and hedonic value of their online store. Online firms can create consumer value by improving the quality of their website and their retail performance. Although both system and service quality affect consumer-perceived utilitarian and hedonic value, online store managers should promote consumers' utilitarian value perceptions of their store by providing easy navigation and high functionality relevant to the type of site, thus forming system quality perceptions, anticipating and responding promptly to customer requests for service, and striving to build an image of professionalism and competence, which all increase system quality perceptions. Finally, this study revealed that information quality and price fairness affect perceived utilitarian value; consequently, online store managers should not only sell their products at a fair and acceptable price but also provide sufficient, reliable, and appropriate descriptions of products, thus fulfilling users' expectations and enabling them to form information quality perceptions. Overall, online retailers who wish to increase their customers' relationship commitment should achieve high value perceptions by enhancing their website quality and retail performance.

Further Research Directions

This study had limitations and its results should be carefully interpreted. One possible limitation was the convenience sampling employed, which was not representative of the entire online shopping population, thus limiting the generalizability of the findings. Therefore, research using stratified random sampling is required to confirm the study's findings. Second, product characteristics have been frequently identified as critical factors in the e-commerce literature, and products can be distinguished as hedonic (i.e., involving aesthetic, sensory, or symbolic benefits; e.g., videos, flowers, perfumes, and fine cuisine)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and utilitarian (e.g., hardware, cameras, and watches) (Cai and Xu, 2011; Lin et al., 2012). Pillai and Mukherjee (2011) extended the concept and demonstrated that an online store can be classified as utilitarian or hedonic based on the store's value proposition. Utilitarian websites, such as search engine and shopping websites, provide goal-oriented information and services, whereas hedonic sites, such as social networking sites and gaming sites (Xu et al., 2012), focus on experiential and sensory stimulation (Sánchez-Franco and Martín-Velicia, 2011).

Furthermore, studies have recognized two dichotomous shopping motivations: the utilitarian motive, underscoring an individual's goal-oriented rationale wherein shopping should be completed in a timely and efficient manner (Xu et al., 2012), and the hedonic motive, relating to an individual's focus on the fun and entertainment of the shopping experience (Francis and White, 2004). Although the present study focused on the role of retail performance in consumers' perceived value regarding online stores, further research should investigate our model in the context of hedonic versus utilitarian online stores; individuals' hedonic versus utilitarian shopping motivations might provide valuable insights. Third, future studies can introduce other antecedent variables of consumers' perceived utilitarian and hedonic value within the model. These other antecedent factors, such as interactivity and the environmental attributes of a website (e.g., social, atmospheric, and design factors), should be identified.

Because of the dramatic increase in online shopping in recent years, the competition between e-stores has become intense and gaining consumer commitment to an online store has become increasingly vital. Delivering product or service value is the ultimate goal of all business entities, so understanding how consumers develop their value perceptions is essential. Investigating the antecedent factors of consumers' perceived values and the moderators of relationships facilitates understanding of Internet-shopping behavior from the perspective of consumers' perceived value.

Chapter 23
Web Content Analysis of Online Grocery Shopping Web Sites in India

Tanushri Banerjee
School of Management, Pandit Deendayal Petroleum University, Gandhinagar, India

Arindam Banerjee
Professor of Marketing, Indian Institute of Management, Ahmedabad, India

ABSTRACT

This article evaluates online grocery shopping web sites catering to customers primarily in India. The process of evaluation has been carried out in 3 parts using Rapidminer. In part A, the authors have studied the similarity in content that resides on the grocery shopping web sites. Using unstructured data from homepage of grocery shopping websites and the keywords specified for the web sites, the authors have made an effort to establish a cosine similarity index amongst them. In part B, the authors have analysed the customer reviews from the web sites. Studying the resulting association rules, authors have attempted to identify the attributes that drive customer happiness. In part C, the authors have documented the web traffic metric parameters (attributes) measured by search engine optimization (SEO) tool web sites. Hence, the created a correlation matrix to determine the parameters that are significantly impacting per day revenue for the web sites.

INTRODUCTION

Shopping for grocery and everyday household products is an integral part of life. In India, buying from a nearby kirana store (small retail store in the neighbourhood in India), ordering products via phone call from the kirana store, picking up groceries from the supermarket are some of the methods adopted by consumers for grocery shopping. The retail market for grocery in India is currently growing at a rate of 10% CAGR (Compounded Annual Growth Rate) which is about the size of 400 billion dollars. Online grocery accounts for only 0.1% of it. However, it is expected to grow to 10 billion dollars in the next 4

years and significantly be concentrated in the urban areas of India. With changing time, consumers have started becoming technology savvy, resulting in widespread use of Internet and mobile phones (Ravish, 2017). E-tailers have identified an opportunity to reach consumers via the online platform, thus beginning the era of online shopping in India. The food and grocery (F&G) market has witnessed the entry of many online players, but over the years only a few have remained operational. However, statistics suggest the growth to increase in the next few years (Thmmiya & Kulkarni, 2017). The online grocery portals provides to prospective customers features such as comparative and competitive pricing, deals and coupons, home delivery options which are otherwise rare in grocery stores. According to a Nielsen survey (Terron, 2012), the urban and affluent consumers in India have opted for the e-commerce as an alternate means of shopping for many such advantages. This digital platform has provided the Indian customer the product, service, query resolutions, content all under the same umbrella of digital shopping.

Grocery market growth in the online space presents a challenge for supermarket chains competing for share, where their investments in online and offline need to be balanced (Francesca & Rettie, 2009). Earlier research related to internet grocery shopping has concentrated on comparing online and offline purchase behaviour in various ways like the importance of brand names (Degeratu et al., 2000), brand loyalty (Danaher et al., 2004), shopping pattern (Andrews & Currim, 2004), and consumers' perceptions of the advantages and disadvantages of online grocery shopping (Ramus & Nielsen, 2005). Study has also been conducted on consumer traits of internet shoppers, either in terms of their general shopping orientation (Brown et al., 2003) their web-usage-related lifestyle (Brengmen et al., 2005), or psychographic characteristics (Barnes et al., 2007). Additionally, literature (Rohm & Swaminathan, 2004) has attempted to develop a typology of internet grocery shoppers, based upon motivations for shopping online.

Another Nielsen survey (Swedowsky, 2009) evaluated the parameters that drive increased consumer interest in online grocery shopping. Convenience, selection, and savings have been stated as primary reasons for choosing online grocery over store shopping. Shipping costs, inability to inspect perishables, and having to wait for deliveries to arrive, have been mentioned as disadvantages of online grocery shopping. There is a significant number of people who continue to shop from stores in-person and have not yet experienced online shopping. Reasons stated have been the habit and preference of the individual or insufficient means to use it due to lack of awareness/availability of online grocery options.

There is opportunity for growth of online grocery shopping due to the following reasons:

1. **Convenience:** Online grocery shopping from home avoids the trips that have to be made to the grocery stores. It frees up the time for other activities and maintain better work life balance.
2. **Generation Y:** Generation Y has a large number of online users. Hence habit and preference of in store shopping that exists with earlier generations is less with Generation Y. Usage of the internet and mobile applications are leading to increase in online shopping.
3. **Broadband and Media:** Growth and penetration of Internet has increased at a rapid pace. Technology savvy customers have ventured into the online shopping space looking for information. Advertisements on media have promoted the advantages of online shopping.
4. **Customization:** Online grocery shopping tracks customer purchase behaviour and hence is able to provide customized recommendations to the customer during following visits to the web site based on previous shopping habits (e.g., product recommendations or promotions for combinations of offerings/kits).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

With growing number of e-tailers providing online platform for grocery shopping in India, there is increased competition within the online grocery shopping market. Research and academic discussion forums debate competitive strategies for their growth and survival. Business Analytics has been used by decision makers to derive insights from customer data leading to survival and growth in a competitive environment. Ramsey and Bapna (2016) have discussed how customers can be identified and text mining/analytics methods that are needed to manage and maximize the processes related to cultivating relationships with these customers. Their paper discusses a means for extracting useful information from text notes captured within a CRM (Customer Relationship Management) system that can be used to segment and thus target groups of customers likely to respond to cross-selling campaigns. These notes often contain text that is indicative of customer intentions.

Analytics is usually defined in practice as any fact-based deliberation which leads to insights and possible implications for planning future actions (Banerjee & Banerjee, 2017). It could range from routine tracking and monitoring of business performance, "nice to know" validation facts regarding the business domain, to more directed diagnosis of 'root cause' of business problems as well as strategic prediction about future business initiatives. The commonality across all these exercises is that it is significantly driven by facts obtained as a part of business and market data collection initiatives by firms. The need for factual evidence-based inference as an input to the business decision process has been in vogue from early times of management history. With the advent of better information gathering process and processing tools, more structured insight building from information is currently the standard expectation in the industry. Large scale digital data is confined mainly to organizations in the e-commerce industry. For grocery shopping websites, some of the common attributes of measuring online presence in a competitive market include the bouquet of product categories offered, the ability to service PAN India, competitive pricing, on time delivery of products and services, discounts offered through deals and coupons, maintaining quality, managing suppliers, handling consumer complaints effectively. While the content displayed on the web site is important along with the look and feel, easy loading of pages, quick navigation between web page links, appearing in searches, referrals from other web sites and a desirable revenue model; equally important is to maintain the optimum products in the inventory, on time delivery, cashback options, deals and discounts, payment options and handling customer queries and complaints. All of these activities generate a huge amount of data that are structured as well as unstructured in nature. Some of the data is consciously captured by the organizations which are used by their Analytics teams to do descriptive and predictive analysis and devise competitive strategies and metrics for measurement of their success online.

A huge amount of data exists in unstructured form like the textual data of the website content, customer buying habits, queries and complaints and so on. Analysts have developed ways of mining this rich source of data for developing insights that can be useful for business growth and profitability. With the advancement of technology, Dashboards have become popular in organizations as visualization methods. From simple analysis to displaying complicated metrics, there has been a slow and steady transition across the industry value chain. What it essentially does is, summarizing the information available from various sources and presenting it in a user-friendly form. Decision makers have appreciated the dashboards as it allows collecting, analysing and presenting huge amount of data being captured by organizations daily and additionally real-time availability of the information (Banerjee & Banerjee, 2017). Statistical methods like web and text mining for evaluating web and textual content on the web sites have become important in analysing unstructured data.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Text mining, also known as text data mining or knowledge discovery in textual databases, is the semi-automated process of extracting patterns (useful information and knowledge) from large amount of unstructured data sources. Text mining is the same as data mining in that it has the same purpose and uses the same processes, but with text mining, the input to the process is a collection of unstructured (or less structured) data files such as Word documents, PDF files, text excerpts, XML files and so on. In essence, text mining can be thought of as a process (with two main steps) that starts with imposing structure to the text-based data sources followed by extracting relevant information and knowledge from this structured text-based data using data mining techniques and tools.

The World Wide Web is perhaps the world's largest data and text repository, and the amount of information on the Web is growing rapidly every day. A lot of interesting information can be found online: whose homepage is linked to which other pages, how many people have links to a specific Web page, and how a particular site is organized. In addition, each visitor to a website, each search on a search engine, each click on a link, and each transaction on an e-commerce site creates additional data. Although unstructured textual data in the form of Web pages coded in HTML or XML are the dominant content of the Web, the Web infrastructure also contains hyperlink information (connections to other Web pages) and usage information (logs of visitors' interactions with Web sites), all of which provide rich data for knowledge discovery. Analysis of this information can help us make better use of Web sites and also aid us in enhancing relationships and value to the visitors of our own Web sites. Web mining (or Web data mining) is the process of discovering intrinsic relationships (i.e. interesting and useful information) from Web data, which are expressed in the form of textual, linkage, or usage information (Turban et al., 2011).

This paper evaluates 10 online grocery shopping sites in India comparing the content on their homepages, customer reviews and also analysing their business performance as summarized on public websites that use search optimization tools and analytical processes. The authors have observed from existing literature that the number of online grocery shopping sites that have currently remained operational across India are few in number. Many of them operate within small geographical areas while others have presence across India. A sample choice of 10 online grocery shopping sites will be able to represent the complete population. This paper aims to study attributes from structured and unstructured data that lead to success of online grocery business in India.

The public web sites that have been considered for this study are as follows:

1. **Bigbasket.com (Bangalore, Mumbai, Delhi, Mysore, Chennai, Hyderabad, Pune, Madurai, Coimbatore, Vijayawada, Ahmedabad, Nashik, Lucknow & Vadodara.):** bigbasket.com has over 18,000 products and over 1000 brands in their catalogue that include fresh Fruits and Vegetables, Rice and Dals, Spices and Seasonings to Packaged products, Beverages, Personal care products, Meats (Bigbasket, n.d.).
2. **Aaramshop.com (97 cities):** AaramShop is a hybrid retail platform that is completely focused on ensuring that customers can shop for daily essentials & grocery brands from the comfort of their homes or offices (Aaramshop, n.d.).
3. **Reliancefreshdirect.com (Mumbai):** Reliance Fresh Direct provides the convenience of ordering groceries online or on phone. Customers can buy various brands and pack sizes of fruits and vegetables, dairy and bakery, staples, packaged food, household and personal care products (Reliancefresh, n.d.).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4. **Askmegrocery.com (Pan India):** Askmegrocery.com aims at fulfilling customers' daily grocery requirements and brings a gamut of products ranging from staples, dairy products, personal care products to other household utilities and thousands of brands (Askmegrocery, n.d.).
5. **Zopnow.com (Bangalore, Hyderabad, Mumbai, Navi Mumbai, Thane, Pune and Gurgaon.):** As a starting point for their vision they plan to achieve first mission of delivering "daily needs" items at customers' doorstep in less than 3 hours. They currently carry items ranging from home needs, personal needs, staples, beverages, spices, edible oil, cleaning utilities, baby products and many more (Zopnow, n.d.).
6. **Fabgrocery.com (Kolkata):** Fabgrocery.com a virtual departmental store, serving across Kolkata. Fabgrocery.com is created to fit into the lifestyle of every Kolkatan. They want to ease the grocery shopping experience for every household with wide range of products, on time delivery, competitive prices and much more (Fabgrocery, n.d.).
7. **Bazaarcart.com (Delhi, Noida, Gaziabad):** At BazaarCart.com one can expect the best prices in Delhi/NCR on favourite grocery items because when they sell online, they can sell stuff cheaper (Bazaarcart, n.d.).
8. **Grocermax.com (Gurgaon):** They promptly deliver what you really want, from an assortment of 10,000+ quality merchandise, at customers' doorsteps, always at a price less than the MRP (Grocermax, n.d.).
9. **Naturesbasket.co.in (Mumbai, Delhi, Bangalore, Hyderabad, Pune):** Godrej Nature's Basket is the retail venture of Godrej Group started in 2005 as a single fresh food store. They have today morphed into a 36-store chain of premium gourmet stores strategically located at high street locations in Mumbai, Delhi/NCR, Pune, Hyderabad and Bangalore and have created online presence via this portal (Godrej, n.d.).
10. **SaltnSoap.com (Kolkata):** SaltnSoap, a BlueBeaks initiative, intends to provide its consumers a convenient, social, enjoyable and rewarding experience of shopping their daily grocery needs online from the comfort of their home and offices (SaltnSoap, n.d.).

Definition of terms used in this research study:

1. **Cosine Similarity index:** Cosine similarity is a measure of similarity between two vectors of an inner product space that measures the cosine of the angle between them. The cosine of 0° is 1, and it is less than 1 for any other angle Wikipedia (n.d.). It is thus a judgment of orientation and not magnitude: two vectors with the same orientation have a cosine similarity of 1, two vectors at 90° have a similarity of 0, and two vectors diametrically opposed have a similarity of -1, independent of their magnitude. Cosine similarity is particularly used in positive space, where the outcome is neatly bounded in [0,1]. In information retrieval and text mining, each term is notionally assigned a different dimension and a document is characterized by a vector where the value of each dimension corresponds to the number of times that term appears in the document. Cosine similarity then gives a useful measure of how similar two documents are likely to be in terms of their subject matter.
2. **Images on Site:** Search engines send out automated programs called "spiders" that crawl web sites and search for what type of content it contains (Roy, 2016). Although spiders aren't able to "see" images, they are able to read the text which is associated with those images.
3. **Alexa Traffic Ranking:** Alexa Traffic Rank is traffic rank of a site. The traffic rank is based on 3 months of historical traffic data collected from the users of Alexa Toolbar. It is combined with

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

different traffic data source and page views (Agrawal, 2017). Alexa counts the number of visitors and number of page views of all the sites for Alexa traffic rank.

4. **Page Load Time:** Page speed can be described in either "page load time" (the time it takes to fully display the content on a specific page) or "time to first byte" (how long it takes for your browser to receive the first byte of information from the web server) (MOZ, n.d.). No matter how you measure it, a faster page speed is better.
5. **Revenue Per Day:** Revenue of the web site on a daily basis. This is mentioned on each of the SEO websites for the respective online grocery site.
6. **Web Site's Worth:** There are several factors that determine the website valuation price. These include age of the website, domain authority, SEO analysis, Page Rank, traffic Rank, social media interaction, website content and many other factors. These factors are all considered to calculate the estimate of how much the website is worth.
7. **Number of Unique Visitors:** A visit is one individual visitor who arrives at your web site and proceeds to browse. A visit counts all visitors, no matter how many times the same visitor may have been to your site. A unique visit will tell you which visitors are visiting your site for the first time. The website can track this as unique by the IP address of the computer. The number of unique visits will be far less that visits because a unique visit is only tracked if cookies are enabled on the visitors' computer.
8. **Number of Page Views:** Once a visitor arrives at a web site, they will search around on a few more pages. On an average, a visitor will look at about 2.5 pages. Each individual page a visitor views is tracked as a page view (Tendenci, n.d.).
9. **Traffic Source via Organic Search:** This indicates the percentage of visitors who visit the site via a search engine (Tendenci, n.d.). There are primarily four different types of traffic sources (the way visitors find the web site):
    a. **Direct Navigation:** (type URL in traffic, bookmarks, email links w/o tracking codes, etc.)
    b. **Referral Traffic:** (from links across the web, social media, in trackable email, promotion & branding campaign links)
    c. **Organic Search:** (queries that sent traffic from any major or minor web search engines)
    d. **PPC:** (click through from Pay Per click sponsored ads, triggered by targeted key phrases)

METHODOLOGY

The authors have conducted this study in 3 parts, all based on secondary data collected from public web sites.

Part A: In part A, the authors have captured unstructured data (textual) from homepage of 10 grocery shopping web sites using the Rapidminer tool's web mining operators. Hence established a cosine similarity index amongst them. The obtained result guide the authors to understand the similarity in terms of the homepage content and keywords amongst the web sites.

The authors have observed that web sites that are designed as retail interface for online grocery shopping have certain design aspects in common. A quick look at the websites indicates that certain content like product categories, product names, login corner, payment link, mobile app link and so on appear

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

in all the pages. In this research work, in part A, the authors have attempted to identify the similarity amongst the homepage textual content of the web sites, thus indicating the difference that exists between them in terms of the online interface content. Using Rapiminer operators, the authors have used the web crawler to connect to the specified web sites and read the content from the homepage. A comparative statistical analysis of the textual content obtained using web mining establishes the similarity index as shown in Table 1.

Output of the Analysis for Part A: From the result obtainined from Rapidminer (Table 1), it can be concluded that the web sites are significantly different in terms of content on the homepage. The highest similarity is seen between the 2nd (askmegrocery.com) and 5th (fabgrocery.com) web sites of 8.1%. The least similarity is seen between the 1st (bigbasket.com) and 2nd (aaramshop.com) and the 3rd (naturesbasket.com) and 5th (fabgrocery.com) websites of 0.28%.

Table 1. Similarity index in %

First website	Second website	Similarity in %
1. Bigbasket.com	2. Askmegrocery.com	0.28
1. Bigbasket.com	3. Naturesbasket.co.in	1.03
1. Bigbasket.com	4. Bazaarcart.com	0.5
1. Bigbasket.com	5. Fabgrocery.com	0.72
1. Bigbasket.com	6. Saltnsoap.com	1.91
2. Askmegrocery.com	3. Naturesbasket.co.in	1.63
2. Askmegrocery.com	4. Bazaarcart.com	3.27
2. Askmegrocery.com	5. Fabgrocery.com	8.13
2. Askmegrocery.com	6. Saltnsoap.com	1.89
3. Naturesbasket.co.in	4. Bazaarcart.com	3.93
3. Naturesbasket.co.in	5. Fabgrocery.com	0.28
3. Naturesbasket.co.in	6. Saltnsoap.com	1.25
4. Bazaarcart.com	5. Fabgrocery.com	0.77
4. Bazaarcart.com	6. Saltnsoap.com	0.94
5. Fabgrocery.com	6. Saltnsoap.com	1.68

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition to homepage content, the keywords specified for organic search for the respective web sites have been documented in Table 2. Organic search is used by majority of online users for seeking information by typing search words in search engines. In India, due to the recent interest and growth of online shopping, search keywords becomes an important dimension of web site design. Keyword optimization (the act of researching, analysing and selecting the best keywords to target to drive qualified traffic from search engines to your website) is an important consideration in the overall web site design for reaching maximum number of prospective customers. It is observed that the most common keywords appearing across all the sites are "online grocery shopping", "home delivery" and "supermarket".

Table 2. List of keywords

NO	WEB SITE	KEYWORDS
1	Bigbasket.com	**online supermarket**, online grocery store, buy groceries online**, grocery online**, Buy food online, grocery, online grocery **shopping**, online grocery, food shopping online, online grocery shopping india[29]
2	Aaramshop.com	CPG, FMCG, FREE **Home Delivery**, **online grocery shopping**, aaramshop, india, lizol, neighborhood retailers, hybrid commerce, allout mosquito repellent[30]
3	Reliancefreshdirect.com	reliance fresh, buy grocery online**, online grocery shopping**, online grocery, reliance one card[31]
4	Askmegrocery.com	**grocery shopping online**, online grocery store, online grocery **shopping**, online grocery store in india, online vegetable shopping, Online Fruits shopping, askme grocery, askmegrocery, ask me grocery, askme grocery offers[32]
5	Zopnow.com	buy online, **supermarket**, Grocery delivery, ZOP, hypermarket, grocery, **online grocery shopping**, online grocery, tata tea gold, zopnow[28]
7	Fabgrocery.com	online grocery kolkata, best online grocery store in kolkata, **online grocery shopping** in kolkata, online grocery store Kolkata, grocery store in Kolkata, grocery shopping in Kolkata, online grocery products in Kolkata, fabgrocery, grocery product kolkata, grocery **home delivery** in kolkata[33]
8	Grocermax.com	vegetables, frozen, grocery online, non veg, grocery, **online grocery shopping**, online grocery, online grocery gurgaon[35]
9	Saltnsoap.com	online supermarket, online grocery store, buy grocery online, grocery, **online grocery shopping**, grocery store india, home delivery, best online grocery store, online grocery kolkata, grocery store Kolkata[34]
10	Naturebasket.co.in	**online grocery shopping**, grocery shopping online, online grocery, online **supermarket**, food online, gourmet food india[27]

Part B: In part B, the authors have analysed customer reviews from the online grocery web sites. Fourteen customer reviews have been considered for the study. The authors have used Rapidminer's text mining operators and association rules operators to analyse them and establish association rule from the textual content. Association rule mining finds interesting associations and correlation relationships among large sets of data items. Association rules show attribute value conditions that occur frequently together in a given data set. They provide information in the form of if-then statements and are probabilistic in nature. In addition to the antecedent (if) and the consequent (then), an association rule has two numbers that express the degree of uncertainty about the rule. In association analysis, the antecedent and consequent are sets of items (called item sets) that are

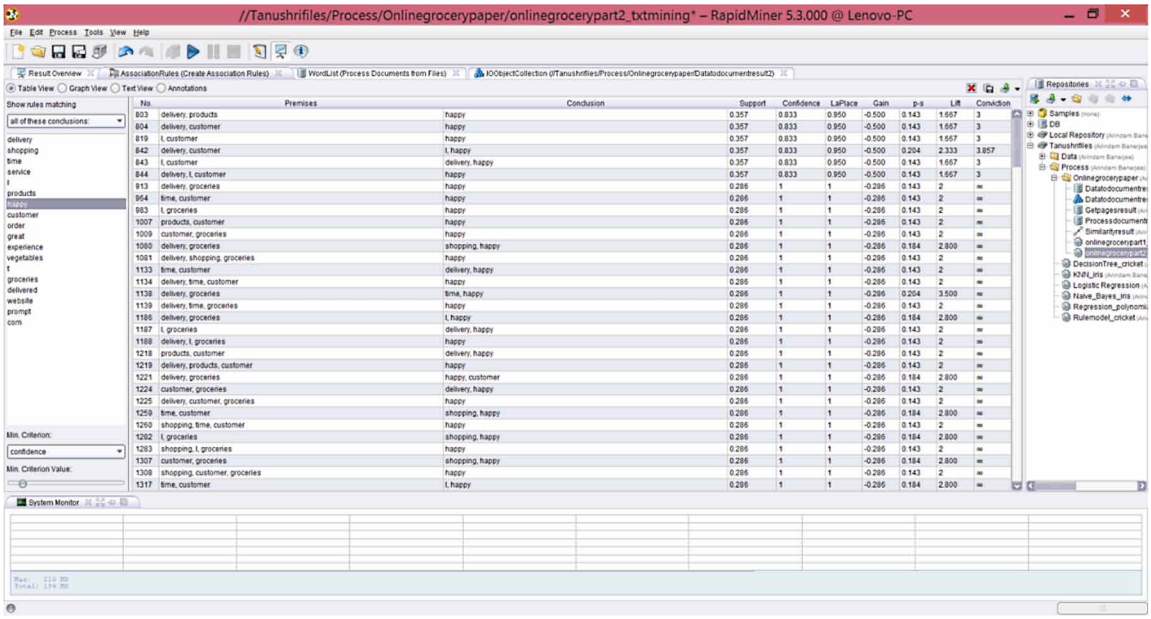
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

disjoint (do not have any items in common). The first number is called the "Support" for the rule. "Support" is the number of transactions that include all items in the antecedent and consequent parts of the rule. The other number is known as the "Confidence" of the rule. Confidence is the ratio of the number of transactions that include all items in the consequent, as well as the antecedent (the support) to the number of transactions that include all items in the antecedent. "Lift" is a value that gives us information about the increase in probability of the then (consequent) given the if (antecedent) part. The authors have evaluated the customer reviews using these parameters and text mining operators of Rapidminer.

The shopping experience of a customer who shops online is considered satisfactory only when the customer is happy with the overall shopping experience. The authors have addressed this hypothesis from the textual content documenting the customer reviews. The grocery websites have a page for displaying customer testimonials. These are either in text form or video files. The video files have been documented to convert them into text files. Then text mining has been used on the complete set of text files. Using "happy" as the indicator to test their hypothesis, the authors have identified the words that are associated with happiness. The strength of the "Support" of those words existing together across the reviews indicates the areas of focus for the e-tailer to provide an overall satisfactory experience to their customers. The authors have further evaluated the "Confidence" and "Lift" for the associated words that have high "Support" value.

Output of the Analysis from Part B: Analysing the "Support", "Confidence" and "Lift" values from association rule for conclusion word "happy" identifies the words to which happiness of a customer is associated. As seen from Figure 1, the "Support" value is 35.7%, meaning 35.7% times of the customer reviews, the word "happy" exists together with the words "delivery" and "products". This

Figure 1. Association rule output from rapidminer



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

indicates that the mention of happiness due to delivery of products has been made only in 35.7% of the total number of reviews. The authors have further noted that there is an 83.3% chance of "happy" existing in customer reviews that mention delivery of products indicating a "Confidence" value of 83.3%. This indicates that the if the customer mentions about delivery of products, there is 83.3% chance of them mentioning happiness. Additionally, the value of "Lift" is 1.667, indicating that occurrence of words "delivery" and "products" has a positive effect on the occurrence of "happy" or that they are positively correlated. We also note that words "delivery" and "groceries" along with "time" and "happy" has a "Lift" value of 3.5, indicating that customers who receive delivery of groceries view it as time saving and are happy with the experience.

Part C: In part C, the authors have captured the parameters (attributes) used by search engine optimization) SEO sites for analysing the online grocery web sites. Then we have tried to identify the correlation amongst these attributes. Several online sites like stattools.com, statvoo.com, informer.com, similarityweb.com and so on have used website usage metrics information and have analysed it using SEO tools and statistical methods. Information used for our study include the following parameters for the 10 websites: daily visitors, daily page views, Alexa rank, page speed score, images on the site in % compared to other content on the site, traffic source on the website of which organic search traffic in %, web site worth in dollars, income per day in dollars. The parameters have been defined in the Methodology section. Using a correlation matrix, the authors have tried to understand the relationship between income per day in dollars made by the web sites to the other parameters, thus identifying the ones that are strongly (> 0.9) correlated. The parameters that have strong correlation to income per day in dollars are the ones that have higher impact on the revenue.

Output of the Analysis from Part C: The correlation matrix in Table 3 indicates a strong correlation between "Daily page views" – 0.97, "Daily visitors" - 0.98, "web site's estimated worth in dollars" – 0.99 to "income per day in dollars". The Alexa ranking is negatively correlated as less the Alexa ranking more visited is the web site. However, from the findings, the Alexa ranking does not seem to be affecting the income per day. Similarly, the number of images on the website, the time taken by the pages to load and the traffic source via search engines do not have significant impact.

Table 3. Correlation matrix

	INCOME PERDAY ($)	DAILY VISITORS	DAILY PAGEVIEWS	ALEXA RANK	PAGE SPEED SCORE (%)	ESTIMATED WORTH ($)	IMAGES (%)	SEARCH TRAFFIC (%)
INCOME PERDAY ($)	1							
DAILY VISITORS	0.978	1						
DAILY PAGEVIEWS	0.970	0.998	1					
ALEXA RANK	-0.392	-0.366	-0.338	1				
PAGE SPEED SCORE (%)	0.225	0.161	0.167	-0.103	1			
ESTIMATED WORTH ($)	0.988	0.969	0.968	-0.313	0.277	1		
IMAGES (%)	-0.459	-0.436	-0.452	0.278	-0.318	-0.523	1	
SEARCH TRAFFIC (%)	-0.077	-0.152	-0.155	0.022	0.768	-0.051	-0.270	1

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

RESULTS

The research conducted led to the following outcomes. The summary of the results can be stated as follows:

In part A, analysis provides the following results:

1. Maximum similarity between the homepage content of online grocery shopping websites (10 considered for this study) is 8.1% and minimum similarity is 0.28%
2. The most common keywords appearing across all the 10 web sites are "online grocery shopping", "home delivery" and "supermarket"

In part B, analysis provides the following results:

1. Happiness with the experience of using the online grocery web site is positively correlated to delivery of groceries.
2. The correlation is stronger when the delivery of the grocery is done timely.

In part C, analysis provides the following results:

1. The income per day in dollars made by the e-tailers of grocery online is strongly correlated to number of visitors on the website, number of page views and web sites' worth in dollars.
2. It is not affected by Alexa ranking, images on the website, the time taken by the pages to load and the traffic source via organic search engines.

DISCUSSION OF RESULT

Results of the study will help identify the keywords that e-tailers of grocery online anticipate the Indian consumers to use while using a search engine to get to online grocery web sites. Common keywords used in search engines would fetch all the web sites containing the keywords. Thus, the results will encourage e-tailers to uniquely differentiate from competitor websites by keyword optimization. It will also identify consumer preferences from the customer review analysis. With the statistically obtained result, the e-tailer is reassured that timely delivery of groceries makes an Indian customer happy. It may be important to identify what else is associated with happiness which did not show significantly due to the limited number of samples used for the study. The result obtained from the correlation matrix will help identify the parameters that drive per day revenue for the online retailer. Due to the limited sample size, further statistical analysis could not be carried out to establish the strength of the impact of the independent variable on per day revenue, however the strength of the correlation identifies the impacting variables. Further studies can help devise creative strategies for optimizing web site metrics for increasing revenue.

CONCLUSION

Originality/value: While study on individual online grocery shopping sites in India have been conducted, the authors have not come across a comparative study of the sites both from the point of content analysis

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

as well as usage information. Results obtained from the study will be useful for online retailers in designing their web sites for generating more revenue and increase number of happy customers. The similarity index will identify the similarity in terms of textual content that exists between their and competitor web sites. The keywords similarity and difference highlight what competing sites use to show up in organic searches. The academic researchers who work in online retailing space can use the results of the study to carry out similar research with larger data sets.

Future Directions and Limitation of Study: Online grocery shopping web sites catering to customers are at its nascent stage and small in number in India. Hence, the limitation of this study has been the small sample size both in terms of the number of grocery online web sites and the number of customer reviews available from the web sites. Similar studies can be carried out with other e-tailer web sites and web portal sites (assortment of products from different vendors) that are comparatively larger in number. Larger data sets and sample size thus obtained can be used to test the association rule and the correlation matrix for further statistical outcomes.

Chapter 24
Online Store Attribute Preferences:
A Gender Based Perspective and MCDM Approach

ABSTRACT

This article describes how purchasing from an online store depends on various attributes of the online store. The relative importance given to a particular factor may vary across gender. Thus, it generates a scope of inquiry for understanding the consumer behavior while making an online purchase. Hence, this article tries to understand the relative importance of the factors affecting consumers buying behaviors while shopping online. This article utilizes Fuzzy AHP and TOPSIS for finding relative weights of criteria and ranking of the alternatives available respectively. The results were analyzed for finding the relative importance of factors across gender. The article finds that security of transactions is the topmost priority for both males and females, but they put a different level of importance on rest of the factors. The results provide valuable insights which can help the online stores in prioritizing the important factors for future improvements.

1. INTRODUCTION

In the internet based commerce or shopping, the consumers are in direct contact with the online store but cannot experience the products directly unlike the brick and mortar shop. This lack of experiencing or touching the product creates various barriers in the minds of consumers towards purchasing online. Therefore, the online stores have to improve various aspects of their services to attract or retain the customers. In other words, the online store cannot provide the direct experience of the product, but it can work on other concerned aspects affecting the purchase intentions of customers.

Currently in India, with the increasing penetration of internet services, the number of consumers buying online is growing at a remarkable pace. According to Forrester report on online retail forecast 2016-2021, Indian e-commerce market is set to grow at the fastest pace in the Asia Pacific region. As reported by IBEF, Indian retail industry is expected to increase at CAGR of 16.7% over 2015-2020. The size of the retail market is projected to be US$1.3 billion by 2020. With the penetration of internet and changes taking place in lifestyle of people, more people are going for an online purchase. Indian online retail sector is projected to grow from US$6 billion to the US $70 billion during FY15- FY20 (www.ibef.org, 2017). These numbers show the potential of this vast market. Therefore, it becomes necessary to study various aspects related to online shopping because of its growing importance.

There are diverse factors which affect the behavior of consumers in a market. The existence of diverse and large number of factors makes it difficult for the online shopping stores to focus their attention on all of them. Therefore, there is need to understand the most important factors which are highly relevant for the consumers. Final decision made by a consumer is based on more than one factor, and this makes it a multi-criteria decision-making (MCDM) problem. AHP is one of the extensively used MCDM methods for decision making, but it is deterministic. As the store attributes like product information quality, security of transactions, etc. are subjective, and it becomes difficult for the consumer to quantitatively allocate a number to these factors. To circumvent with this problem, this paper makes use of the fuzzy AHP approach.

This paper discusses the use of fuzzy AHP to understand the relative significance of various store attributes for a consumer buying online. This is done by computing the weights of some relevant factors affecting the consumer behavior. Weighing the factors helps in prioritizing them for business improvement and make better business decisions (Cheng & Li, 2001). Hence, the main aim of this study is to find relative importance of store attributes for shoppers (males and females).

The paper is structured as follows. The first section gives a brief introduction about the online buyer behavior with special reference to India. The second section reviews the relevant literature on store attributes, consumer behavior in online shopping and their relationships. It also involves the review of studies focusing on studying the effect of gender in shopping behavior. The third section describes the design of study and method used to prioritize the factors. The fourth and fifth sections present the analysis of data. The last section concludes and discusses the implications of findings for online stores or e-commerce websites.

2. LITERATURE REVIEW

2.1. Online Shopping Behavior

The growing importance of online shopping has led the researchers to increasing study and analyse this aspect. There are many studies which focus on understanding the factors which affect the behavior and purchase intentions of the shopper or consumers. These studies help the online shopping websites to improve upon various aspects related to their services. One of the factors which play an important role in consumer response is the experience gained by the customer. This is because of the fact that shopping is not only a mechanical process, but also an enjoyable experience for many customers. This experience of the customer gets affected by many other factors (Won Jeong, Fiore, Niehm, & Lorenz, 2009). Jeong et al. (2009) studied the impact of website features like product presentation on the responses of the consumers. The experiential value gained by the consumer changes with the types of product presentations on apparel websites.

The business model of e-commerce players is such that they aim to create an online shopping habit which they could encash in the future. This industry is still at nascent stage, and it is emerging. The present study proposes to study the impact of gender on various factors affecting the purchase behaviors. This type of study is relevant because as the consumers gain experience in online shopping then their socioeconomic characteristics like age, gender and income do not moderate the perceptions of e-commerce (Hernández, Jiménez, & José Martín, 2011). However, as the industry is at the nascent stage now, it becomes imperative to study the effect of gender or other socioeconomic factors on their intentions.

The content and the way of presentation of products on website impacts the consumers' willingness to go to a particular online store (Park & Kim, 2003). As the number of players in online shopping industry is increasing, the competition is going to be fierce in future. As the customers become more experienced in online shopping, they shift their focus from within chain across multiple channels to across multiple stores within the online channel, making the assortment and attractiveness more imperative in selection (Melis, Campo, Breugelmans, & Lamey, 2015). The competitors will have to differentiate their store from others to make more and more customers choose their store. Because the website with unpleasant visual and navigational design and lack of information about the product may irritate the customers (Hasan, 2016), it may have a negative impact on purchase intentions of the consumer. Therefore, it is vital to devote attention to the attributes of online stores. The characteristics of online stores have been categorized into four categories: Merchandise, navigation, customer service, and convenience, and security (Lohse & Spiller, 1998):

- **Merchandise:** This attribute includes product-related aspects like variety and assortment of the products and product information available. Customers prefer a large variety of products to select from (Lohse & Spiller, 1998). According to Lohse and Spiller (1998), most sellers do not exploit the opportunity of providing detailed product information on the store. The online stores should give some emphasis on the informational content of websites to make certain that customers are not provided with unnecessary information (Hasan, 2016), which may lead to distraction and irritation;

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

- **Service:** This is the second attribute of online store, which indicates the level of service responsiveness of the store (Lohse & Spiller, 1998). Various aspects involved in service attribute are payment policies, response to FAQs, information about the shipping and quality of the products, gift services, promotions, and offers. The promotion may include the frequent buyer schemes, product related tips, and events to attract the customers;
- **Navigation and convenience:** The convenience attribute includes the store design, organization characteristics and simplicity of use. This may also involve the checkout in the least possible time and help indicators wherever required. Navigation has been characterized by features like product search, overall site design, organization, and reliable navigation links to browse the website faster. The user interface is the only thing through which the customer interacts with the store and vice versa, and it is the first thing which forms an impression on consumers' mind. Therefore, it becomes highly essential to improve the user interface to minimize the effort of the user by focusing on navigation and convenience. As shopping is not a process only, it is a fun activity for many shoppers;
- **Security:** Risk perceptions regarding internet privacy and security are emerging nowadays. It has been recognized as an important concern for both new and veteran users (Miyazaki & Fernandez, 2001). Buyers want to be assured of the protection of their private information and secure transactions while buying something. Consequently, users' perception of the security features of a particular online store will also impact their purchase decisions.

The present study will find the order of preference of these attributes of an online store so that the retailers can focus on improving the highly preferred attributes. The existing literature explains the gender differences in purchase intentions, and various factors that are affecting both the genders differently. In that context, this paper tries to find how the gender differences create a difference in the preference order of the attributes.

Majority of the existing studies have been performed for the shopping of apparel products online. The acceptance of online shopping differs across the categories of products (Lian & Lin, 2008). Accordingly, the criteria affecting the purchase intention may also differ across the category of products. Without any doubt, apparel is one of the major categories of products sold online. However, there are other types of products frequently bought over the internet like electronic products. There is a need to study the factors affecting the purchase intentions towards electronic products. Future studies may look at more than one product categories.

The attributes of online stores do not convey their complete meaning from their names because they include many sub-factors in them. Therefore, to make it more feasible for the decision makers, the subfactors have been chosen to convey the meaning of those attributes. For symbolizing merchandizing attribute, product variety and amount of product information provided have been chosen as the criteria. Similarly, to indicate the service and promotion attribute, payment policies and offers and schemes have been chosen. From convenience and navigation attribute, ease of using the website is taken. Then the last security attribute is framed as the security of transactions. In addition to this parameter, one extra parameter which is included is the trust towards e-commerce brand or company. Gefen et al. (2003) have pointed out that along with other aspects like ease of use and perceived usefulness, trust is also an important factor for online shopping.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.2. Differences in Gender

Many studies have reported the difference in the online shopping behaviors of males and females. The difference in orientations and willingness to purchase (Hansen & Møller Jensen, 2009), different attitudinal components (Hasan, 2010) and risk perceptions and acceptance of recommendations (Garbarino & Strahilevitz, 2004) for males and females have been studied. Women perceive more risk in the online purchase and are frequent in buying products recommended by their friends. Also, there is a difference in the level of internet usage across the genders. A quite significant gender difference has been reported in the cognitive attitudes of persons. It is found that females value the usefulness of online shopping less as compared to males (Hasan, 2010). Also, females more often shop for fun and men are the quick shoppers (Hansen & Møller Jensen, 2009).

The perceived ease of purchasing online has more significant effect on attitude and buying intentions of females vis-à-vis males. However, the impact of personal awareness of the security is more in males (Chiu, Lin, & Tang, 2005).

3. METHODOLOGY

As it is clear from the extant literature, some factors affect the decision-making process of the consumers. With the increasing competition, it is of paramount importance for online retailers to attract customers to their website. It is clear that there are a large number of factors which affect the user intention. In this paper, we aim to find out the most significant factors which affect the user intention. The insights derived from this study would help the retailers in improving their services and making better decisions. To achieve this purpose, the present study uses one of the multi-criteria decision-making models as the decision made by the users is based on multiple parameters. AHP provides the means to prioritize the factors and identify the interrelationships that exist among them (Saaty, 1988).

3.1. Modified Delphi Method

Delphi method obtains and examines the results presented in written, oral and feedback formats by anonymous specialists (C.-W. Chang, Wu, & Chen, 2008). Delphi method involves five steps: "1) selecting the anonymous experts; 2) conducting the first round of survey; 3) conducting the third round of questionnaire survey; 4) conducting next round of survey; 5) integrating the expert opinions to reach consensus" (Sung, 2001). According to Murry and Hammons (1995), the minimum size of panel is suggested to be 10 and maximum can be 25-30. As the chances of new idea generation in a homogenous group decrease when the size approaches thirty participants. Therefore, the number of participants selected for the present study is limited to 25. In order to study the impact of gender, 25 males and females have been selected to participate in the panel. To make sure that the participants are capable enough to express an opinion about online shopping of electronic goods and online store attributes, the selection criteria are that they must have bought an electronic gadget like TV, mobile phone, etc. online during the period of last three months.

In the first round of the survey, the participants were requested to assess the available criteria on a scale of 1-5 based on its importance while making an online purchase. After this round, top 7 criteria were selected for applying fuzzy AHP approach. In next round, males and females were provided with the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Fuzzy linguistic scale

Linguistic Scale	TFNs	Reciprocal TFNs
Equally important	(1,1,1)	(1,1,1)
Weakly more important	(2/3,1,3/2)	(2/3,1,3/2)
Strong more important	(3/2,2,5/2)	(2/5,1/2,2/3)
Very strong more important	(5/2,3,7/2)	(2/7,1/3,2/7)
Absolutely more important	(7/2,4,9/2)	(2/9,1/4,2/7)

questionnaire containing pairwise comparisons of the criteria selected in the last step. Then Fuzzy AHP was applied to responses of each of the participant and aggregated result of the panel was presented. In the third round of the survey, the participants were allowed to change the selections made in last round. Again, the results of third round were presented, and participants were allowed to make further changes. After the fourth round, the responses of the participants showed significant convergence. Thus, the cycle of the survey was stopped. The responses of last round of survey were then used to calculate the final weight of the criteria by using Fuzzy AHP Approach.

3.2. Fuzzy AHP (Analytic Hierarchy Process)

To make complex decisions based on multiple criteria, some organization is needed. This can be the hierarchical representation of factors and alternatives (Saaty, 1988). This hierarchy of goals, characteristics, and issues provides a full picture of the intricate problem and assesses whether issues at one level are of the same scale (Saaty, 1990). According to Saaty (1990), "AHP is how to derive relative scales using judgment or data from the standard scale and how to perform arithmetic on such scale avoiding useless number crunching." In AHP, the decision maker is probed to assign pairwise comparison ratios to the attributes or factors at each level of hierarchy because the pairwise comparison concentrates on the judgment. These comparisons can be done on the basis of criterions recognized in memory through experience (Saaty, 1990).

The traditional AHP is used for the deterministic and crisp situations, but the situations involving some degree of vagueness cannot be dealt with normal AHP. In that case, Fuzzy AHP is used, in which the pairwise comparisons are expressed in terms of fuzzy numbers. Then these comparisons are aggregated, and final priority vector is synthesized.

In the extent analysis method proposed by Chang (1996), the degree to which an object can achieve a goal is considered. This extent is quantified by using triangular fuzzy numbers. The Triangular Fuzzy numbers (TFNs) are used for expressing the pairwise comparisons among the criteria or attributes. TFNs are denoted as (l, m, u) where l<= m<= u for a fuzzy event. The TFN scale used in the present study is shown in Table 1.

Using this TFN scale the fuzzy comparison matrix is constructed for all the attributes. As there are seven attributes to be compared in the present study, so the 7x7 matrix is constructed for them. The fuzzy judgement matrix A={aij} is of the form:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

$$A=\begin{bmatrix} 1 & a12 & \dots & a1n \\ a21 & 1 & \dots & a2n \\ \vdots & & & \vdots \\ an1 & \dots & \dots & 1 \end{bmatrix}$$

Here aij if a TFN of form aij=(lij,mij,uij). For each TFN, the membership function is continuous mapping for real number $-\infty \le x \le \infty$ to the closed interval [0,1]. The membership function, μa(x) is given by:

$$\mu a=\begin{cases} \dfrac{x-l}{m-l}, l \le x \le m \\ \dfrac{u-x}{u-m}, m \le x \le u \\ 0, otherwise \end{cases}$$

The responses collected from multiple experts are combined by using the fuzzy geometric mean method as suggested by Buckley (1984). In the next step, the fuzzy synthetic degree values are obtained by using following formula:

$$Si=\sum_{j=1}^{m} M_{gi}^{j} \otimes \left[\sum_{i=1}^{n}\sum_{j=1}^{m} M_{gi}^{j}\right]^{-1}$$

The degree of possibility of $M2 \ge M1$ is defined as:

$$V\left(M2 \ge M1\right) = \sup_{y \ge x} \min\left(\mu_{M1}\left(x\right), \mu_{M2}\left(y\right)\right) \text{w'(Si)}$$

$$\mu_{M2} = \begin{cases} 1, & if\ m2 \ge m1 \\ 0, & if\ l1 \ge u2 \\ \dfrac{l1-u2}{\left(m2-u2\right)-\left(m1-l1\right)}, & otherwise \end{cases}$$

Each w'(S) value represents the relative weight or preference of one criterion over another. These weights are then normalized to obtain $W=(w(S1),w(S2),\ldots,w(Sn))^T$. These weights are required to calculate the rank or score of the attributes.

To ensure the consistency in the responses of the decision makers, consistency ratio (CR) is computed for comparison matrix. CR is ratio of Consistency Index (CI) and Random Consistency index (RI). The values of RI have been suggested by Saaty (1990) depending on some criteria compared. If CR is less than 10%, then the comparisons are acceptable:

$$CI = \frac{\lambda_{max} - n}{n-1}$$

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 2. Aggregated response matrix for male responses

	Variety of Products	Product Information	Mode of Payment	Offers	Ease of Use	Security of Transaction	Trust
Variety of products	(1,1,1)	(0.73,0.9,1.14)	(1.04,1.29,1.59)	(0.68,0.85,1.07)	(0.74,0.96,1.25)	(0.40,0.46,0.52)	(0.56,0.69,0.87)
Product information on website	(0.88,1.09,1.36)	(1,1,1)	(0.81,0.98,1.17)	(0.57,0.73,0.94)	(1.14,1.51,1.96)	(0.42,0.48,0.56)	(0.68,0.85,1.06)
Mode of payment	(0.62,0.77,0.96)	(0.84,1.01,1.22)	(1,1,1)	(1.01,1.18,1.38)	(0.59,0.76,0.98)	(0.6,0.74,0.9)	(0.6,0.77,1.00)
Offers or discounts offered	(0.93,1.18,1.47)	(1.06,1.37,1.75)	(0.72,0.84,0.98)	(1,1,1)	(1.20,1.56,2.00)	(0.54,0.66,0.8)	(0.77,0.97,1.24)
Ease of use of website	(0.79,1.04,1.34)	(0.51,0.66,0.87)	(1.02,1.31,1.68)	(0.5,0.64,0.83)	(1,1,1)	(0.56,0.69,0.85)	(0.52,0.58,0.67)
Security of transaction performed	(1.90,2.19,2.47)	(1.77,2.07,2.39)	(1.10,1.35,1.66)	(1.24,1.53,1.86)	(1.17,1.45,1.78)	(1,1,1)	(0.97,1.18,1.4)
Trust on online store	(1.15,1.45,1.79)	(0.94,1.18,1.47)	(1.00,1.29,165)	(0.81,1.03,1.31)	(1.48,1.71,1.92)	(0.71,0.85,1.03)	(1,1,1)

The fuzzy eigenvector of A matrix is calculated by using:

$$Vi = \left(\prod_{j=1}^{n} aij \right)^{1/n}$$

$V_1=(a_{11}*a_{12}*.....*a_{1n})^{1/n}$

.....

$Vn=(a_{n1}*a_{n2}*.....*a_{nn})^{1/n}$

The Eigenvector V_i is compounded as $V = (V_1, V_2,.....V_n)$. For testing the consistency, Saaty proposed following relation:

$\lambda m_{ax} = V * w$

Here, w is computed by summing the columns of preference matrix. For example, for responses from males, the aggregated response matrix is shown in Table 2.

W= ((7,9,10) (7,8,10) (7,8,10) (6,7,8) (7,9,11) (4,5,6) (5,6,7))

V = ((0.70,0.84,1.1) (0.74,0.90,1.07) (0.734,0.87,1.05) (0.86,1.04,1.26) (0.67,0.81,0.99) (1.26,1.48,1.72) (0.98,1.18,1.41))

$\lambda m_{ax=}$ (5.15, 7.36, 72.8)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

If the central number is taken as a crisp number corresponding to $\lambda m_{ax,}$ then CI = 0.06 and CR = 0.05 < 0.1. Hence, the comparison matrix is consistent. Similarly, for the comparison matrix for females' responses were also consistent.

3.3. TOPSIS

Topsis (Technique for Order performance by the similarity of Ideal solution) is one of the multi-criteria decision making or multi-attribute decision-making methods. In this method, the decision makers structure the problem to be solved, and then after comparison, rankings of the alternatives are calculated. This ranking is calculated by relative closeness to positive and negative ideal solutions. Because of sound logic, simple computation process and a scalar value that accounts for both positive and negative ideal solution, Topsis is a major MCDM approach among others (Shih, Shyur, & Lee, 2007).

Topsis is a practical technique for selecting the alternatives based on multiple criteria of evaluation. The calculation is based on the method of estimating the distance of each alternative from best solutions (both positive and negative). The solution should be nearest to the positive ideal solution and farthest from the negative ideal solution. This method has several advantages over other MCDM/ MADM approaches like a scalar value is used which takes into account both positive and negative ideal solutions simultaneously. Also, the computation is more straightforward and can be done quickly in a spreadsheet. It further helps to integrate various measurement units into one dimensionless unit (Kim, Park, Chan, & Yun, 1997).

As in most of the practical decisions, more than one decision makers are involved. Therefore, the alternative preferences of various decision-makers need to be combined. According to TOPSIS extension proposed by Shih et al. (2007), the separation measures can be calculated after calculating the geometric or arithmetic average of the individual responses. In the present study, the responses of the DMs have been combined by taking the arithmetic means of individual responses.

In TOPSIS, the collected responses are normalized using:

$$r_{ij} = x_{ij} / \sum x_{ij}^2$$

x_{ij} is score of an option i with respect to criterion j and there are m number of options and n number of criteria. After this step, the weighted normalized decision matrix is created:

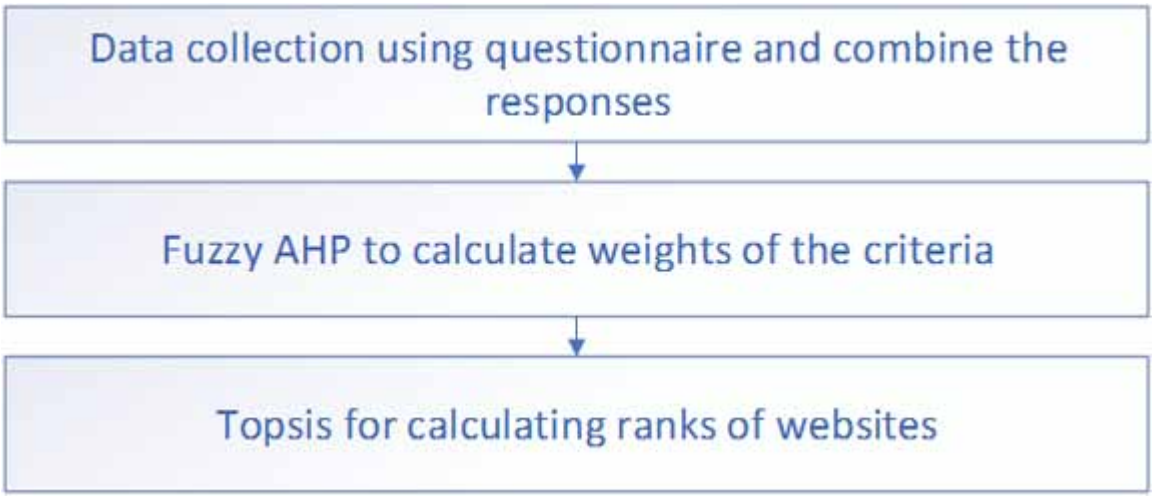
$$v_{ij} = w_j * r_{ij}$$

Then, the separation measure is calculated for each alternative which indicates the separation of an alternative from the positive and negative ideal solutions. These measures are obtained as:

$$S_i^* = \left[\sum_j \left(v_j^* - v_{ij}\right)^2\right]^{\frac{1}{2}}, i = i,\ldots,m alternatives$$

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Flow of study



Here v_j^* corresponds to positive ideal solution values. Similarly, the separation values S_i^{*-} can be calculated from negative ideal solution. By using these separation values the relative closeness to ideal solution C_i^* is calculated by using:

$$C_i^* = \frac{S_i^{*-}}{S_i^* + S_i^{*-}}, 0 < C_i^* < 1$$

Based upon the values of closeness index, the alternatives are ranked. The highest value of closeness index implies the best alternative among the available options.

4. PROPOSED MODEL

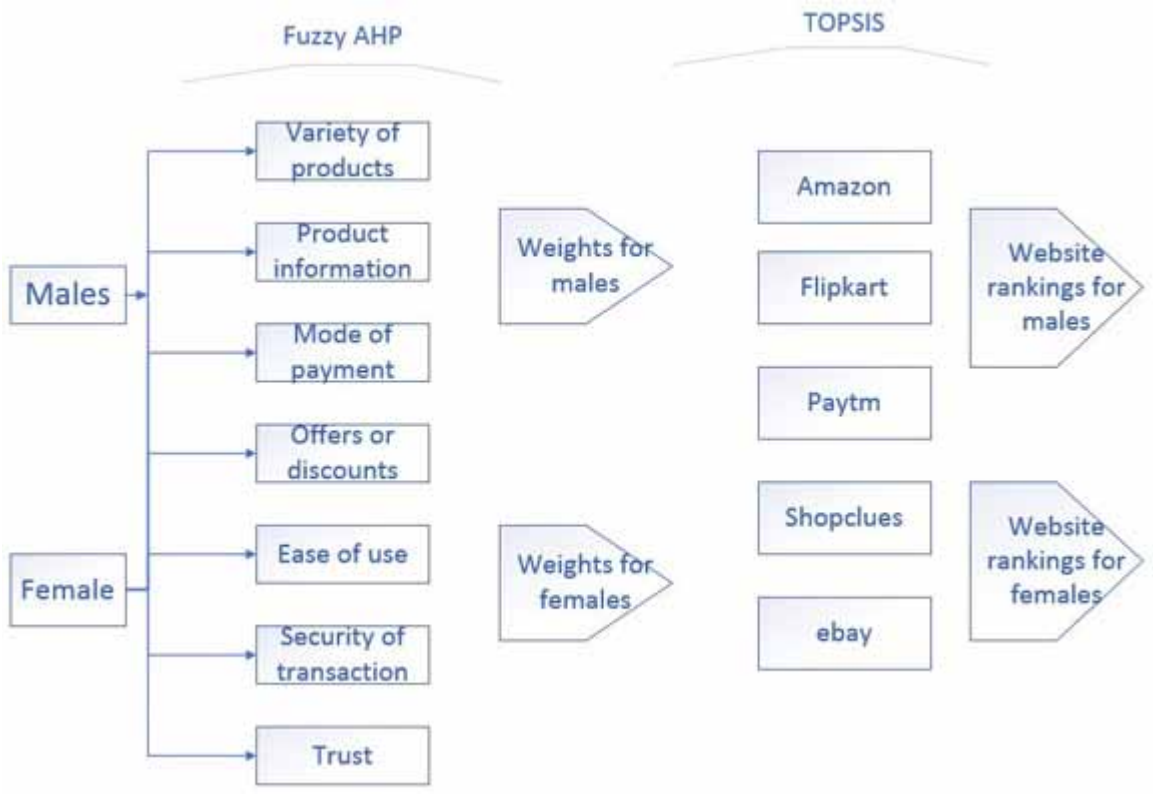
In this era of targetting a particular segment of customers, it becomes highly essential to classify and target them based on gender. The extant literature also clearly points out that the gender plays an important role in consumer choice making, and males and females behave differently while shopping. However, the question is how they should be targetted in the online scenario, where there is no direct contact with the customer. In case of online shopping, the customer interacts through the interface and comes across various store attributes like merchandise, services, etc. It is of great consequence to know about the dominant attributes influencing the consumers with different genders. This study helps to address this need. The results will help online stores to improve their characteristics and attract more customers.

Figure 1 shows the flow of study.

First, the Delphi method is used to collect the responses about various store attributes and their relative importance. Then, these responses from both genders are subjected to fuzzy AHP application, and final weights of the factors are calculated. These weights act as input for next step, i.e., TOPSIS. In this step, the alternative online shopping websites are compared based on the criteria or factors selected in

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. Detailed architecture of study



previous steps. Finally, this leads to the priority list of the alternatives for the consumers. However, the primary focus of the study is to find relative importance of factors, which is the result of the second step (see Figure 2).

Steps to be performed:

Step 1: Data collected on the preference of criteria (from both the genders) is converted from linguistics to corresponding fuzzy numbers and is subjected to fuzzy AHP method.
Step 2: Eigenvector method is used for calculating the weights of criteria.
Step 3: Major market players, who sell electronic products along with other products, in the e-commerce industry are selected.
Step 4: Data collected about the e-commerce website ratings on selected criteria is then subjected to TOPSIS for selecting the most preferred one.
Step 5: Calculation of S* (positive ideal solution) and S*- (negative ideal solution).
Step 6: Then by using S* and S*-, compute the closeness ratio to select the best alternative finally.

Although, the results can be obtained by using only fuzzy AHP for both calculating the weights and evaluating the alternatives yet the present study adopts a hybrid model of fuzzy AHP and TOPSIS. This is because the prime motive of the study is to find the relative significance of attributes, rather

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Weights of the store attributes for both males and females respondents

Attribute	Males	Females
Variety of products	0.068	0.122
Product information on website	0.105	0.158
Mode of payment	0.07	0.148
Offers or discounts offered	0.166	0.156
Ease of use of website	0.057	0.122
Security of transaction performed	0.32	0.165
Trust on online store	0.21	0.129

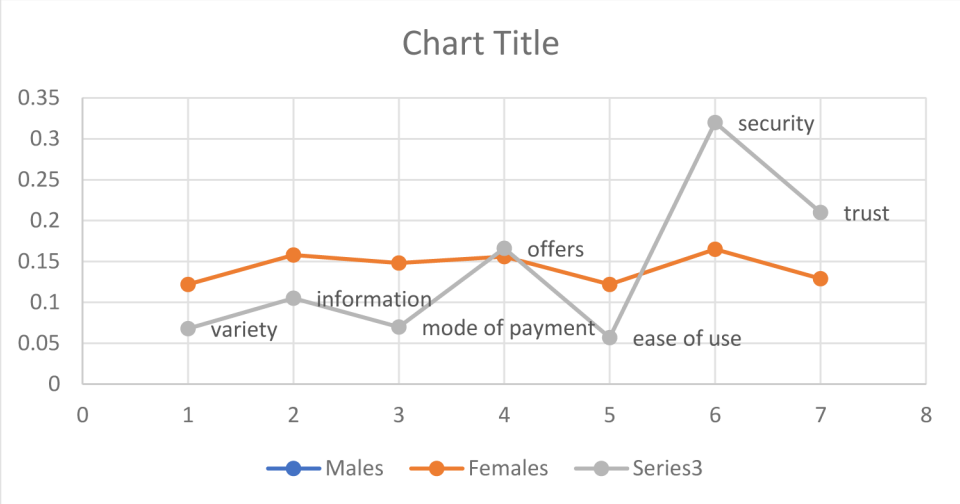
than evaluating the performance of few stores with respect to those attributes. Also, TOPSIS has some advantages as compared to other MCDMs. Therefore, the hybrid model is used in this study.

5. RESULTS AND DISCUSSION

After the first round of the survey, the seven criteria selected are variety of products offered, product information provided on the website, mode of payment, offers and discounts, ease of use of the website, security of the transaction performed and trust for the online store. The relative weights of these criteria for males and females are shown in Table 3.

The 'security of transactions' performed is the priority for both males and females. This may be due to the spread of awareness about the risk related to security and privacy of online transactions among the young population. For males, the 'trust' on store is the second highest factor, while for females it is 'offers and discounts'. This finding is in line with that of Hasan (2010) showing that females are less utility oriented buyers as compared to males. This encourages females to get more attracted towards 'of-

Figure 3. Graph showing the difference between the preferences of males and females



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

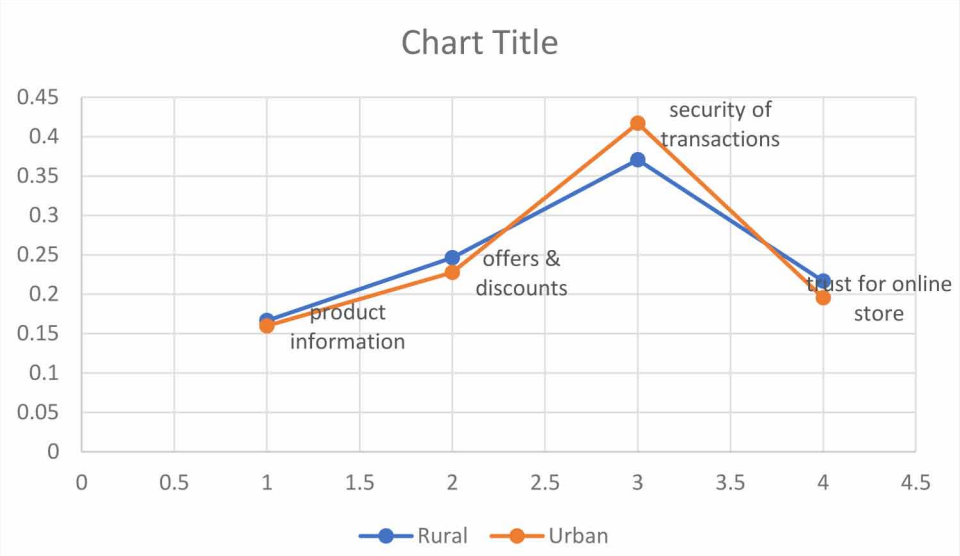
Table 4. Weights of top four store attributes assigned by rural and urban customers

	Rural	Urban
Product information	0.166434	0.159847
Offers & discounts	0.246154	0.227621
Security of transaction	0.370629	0.41688
Trust for online store	0.216783	0.195652

fers and discounts' while males look for 'trust' towards the online store so that they can get the assurance of maximum utility of the purchase. The females place relatively more weight on 'product information' on the website as compared to males, which may be attributed to their spectrum of awareness. The males are generally more aware of the characteristics of electronic products while the females have to rely more on the information provided on the website. Both of them give low importance to the 'ease of use' and 'variety of products'. This may be attributed to the fact that the quality of technology and store interface has improved a lot, over past few years. This makes the 'ease of use', a taken for granted factor. Because absence of this factor implies that the store does not have a proper infrastructure to cater to needs of customers and thus it cannot survive for long in the market. Moreover, the electronic goods are high investment products, so the consumers made their mind about the type of product they want to buy. Consequently, the availability of a variety of products does not make much difference (see Figure 3).

As evident from the graph that, for both males and females the top four criteria are 'product information', 'offers & discounts', 'security of transactions' and 'trust' for the online store. For further digging into the data, the responses were divided based on the type of area of residence of the participant, i.e., Urban or Rural. Table 4 and Figure 4 show the relative weights of these four criteria:

Figure 4. Weights assigned by rural and urban customers for four attributes



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 5. Ranks of the five alternatives using TOPSIS

	C_i (m)	C_i(f)	Rank(M)	Rank (F)
Amazon	0.91	0.93	1	1
Flipkart	0.63	0.76	2	2
Shopclues	0.13	0.29	4	4
Paytm	0.45	0.32	3	3
Ebay	0.09	0.13	5	5

For the second step of the study, five top e-commerce websites have been chosen as alternatives. The participants were asked to rate the websites on a scale of 1-5 for each criterion studied in the first phase. Then, the TOPSIS is applied to their responses to get final ranks of the websites. In TOPSIS, the alternatives are evaluated by its relative closeness to the positive ideal solution. The closeness is indicated by calculating a parameter called closeness index (Ci) (see Table 5).

The ranks of the websites came out to be equal, and the possible explanation for this is that the consumers perceive Amazon as best at almost all the criteria and the last ranked website bad on almost all criteria. This does not give the useful insight about the consumers, but the first part of study offers useful insights for online stores.

6. IMPLICATIONS AND FUTURE RESEARCH

The results of present study indicate, the male and female consumers behave differently while shopping online. They assign different weights to various factors. Therefore, it is essential to deal with them separately. The results of the study can be helpful in forumulating advertising schemes and promotional offers. Both males and females should be fortified against the security and privacy attacks online. The 'offers and discounts' entice the female consumers whereas the 'brand reputation' and 'trust' attract male customers. Another important implication is that the female customers should be provided with more relevant information about the product on the website.

The future research work can focus on incorporating the other product categories. Also, the relative importance of the store attributes can be empirically tested to verify the results. The analysis of the customers' choice based on other demographic characteristics can be performed. The future studies can also focus on analysing the differences in the preferences of the rural and urban customers and further categorizing them according to gender. Another demographic factor that can play a role in customer preferences is age group of the customers. It is highly likely that the customers will exhibit different preferences. This may help in further customizing the services according to the needs of the customers.

ABSTRACT

Online shopping is nowadays is a highly frequent action but there are several critical factors that have to be considered for enabling websites and platforms to be able to offer all necessary requisites for guaranteeing user friendly, secure and also enjoyable shopping experiences to clients, offering them exactly what they expect to buy, and quickly find, among a huge offer available online. In this paper, a set of considered critical success factors are analysed on a set of top ranked websites, about luxurious furniture, to understand to what extent these critical factors are satisfied. The results can be taken into consideration for implementing a successful business through e-commerce from herein analysed perspectives.

1. INTRODUCTION

Online shopping is growing fast as an interesting alternative way of buying experience, which has emphasized the relevance of the growing instrumentalization usefulness of the web through websites and platforms for supporting e-commerce (Alturas, Santos & Brites, 2006). Essentially, e-commerce is a type of e-business involving goods, services and information in which the parties involved do not always meet physically but interact electronically. The benefit of e-commerce is of course evident. For example, the potential of placing orders, transferring sales data and inventory information, and conducting the transactions online can significantly reduce business operations cost and increase the speed of business activities.

Given the existing competitiveness in the nowadays global market context, there is an increasing need to reach the maximum number of customers within particular niche markets (Abdallah & Jaleel, 2014). E-commerce provides many opportunities for business to reach markets that have never been possible to reach before the Internet age. Therefore, e-commerce can create significant value and generate extra sales through the virtual marketplace. Although e-commerce is already being widely explored, there is still considerable margin of growth to its maturity (Ascensão, 2011). Furthermore, there is no guarantee that companies selling their products and services through Internet channels will be successful. Many businesses have now realized that installing computer networks inside the company and creating a website may appear easy. But building a profitable business to fulfil customer's orders online is actually a lot harder. A major challenge for e-commerce success lies in the question of how to use e-commerce to help create a sustainable competitive advantage (Bandyopadhyay, 2010).

There are a vast number of studies demonstrating the successful implementation of e-commerce, in many industrial sectors (Ascensão, 2011), which led to a strong motivation for this work, in order to further the study of the critical success factors for implementing successful businesses through e-commerce from multiple perspectives.

Thus, in this paper, a study of the whole process of online shopping, with special focus on critical success factors analysis is presented and discussed. The paper is organized as follows. In section 2, a brief description of the market behind e-commerce is presented. In section 3 an extensive review on the state of the art is included, with the research gap identified. Section 4 proposes a multi-perspective critical success factor analysis and discusses, in detail, each of the critical success factors to be considered when putting forward an online shop. In section 5 are presented and briefly discussed some results obtained regarding the main critical success factors studied through a questionnaire carried out in this work. Finally, section 6 puts forward some main conclusions and planned further work.

2. MARKET DESCRIPTION

The competitive global market of today requires companies to be in all parts of the world at the same time. E-commerce is a sophisticated tool for opening new business opportunities with a considerable competitive advantage over local markets (Becerra & Korgaonkar, 2011). Although there is already a great adherence and growth of e-commerce, it is expected that this still has a high degree of progression.

The demand for niche markets and marketing allies could revolutionize the new e-commerce. Recent technological changes allow cementing online business by providing payment procedures in a safer way up to highly effective logistic companies. The whole process of creating online stores involves many

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

techniques and multidisciplinary areas, requiring a synergy of skills for obtaining the desired result (Brege, Brehmer & Rehme, 2008). Thus, much attention has to be paid to a variety of subjects related with this issue, including the study of implications of e-commerce at different levels of impact, particularly in terms of human behaviour and preferences, as well as the analysis of alternatives for its implementation.

Understanding what drives an online shopper to buy online through a website, as an alternative to traditional commerce is one of the goals that distinguish a successful project, from an inconsequential attempt. A well-known challenge for a successful online business provider is that it needs involvement from multiple disciplines, such as engineering, design, computing, communications, logistics, marketing and even psychology.

Along with the increasing success of e-commerce in global markets in recent years, especially since middle 1990s, it has been recognized that e-commerce success has been hampered by a number of reasons. One of which is the lack of conceptual frameworks that can develop and provide effective success measures (Varela et al., 2016). The work presented in this paper is motivated by this recognition and aims to contribute to the development and provision of an integrated view to define critical success factors for online shopping. The following section will provide a comprehensive literature review on the topic (Burgess, 2008).

3. REVIEW ON E-COMMERCE

E-commerce has not evolved at the same rate in quality, although there has been a rapid growth in terms of quantity. The possibility of creating an online store and start selling immediately, without huge investment cost as an obstacle, has provided many people with no relevant knowledge to invest in this area. It is easy to prove this observation by searching online stores which, for instance, simply do not allow the understanding of how one can buy a product when being faced with a confusing website that encourages the user to immediately close the web page, even before taking a look on its contents.

Therefore, there is still much room for improvements, by applying the logic of critical success factors. Although there are some online stores performing relatively well, designing an online store without any insightful investigation of potential success factors may turn out to be hard to succeed.

There has been a considerable amount of work carried out to identify, to measure and to evaluate critical success factors in e-commerce during recent years. Those identified, measured and evaluated success factors can be classified using a number of classification schemes (see for example, Cebi, 2013; Chen & Chou, 2012; Clements, Dean & Cohen, 2009; Duncan, 2011; Fang, Chiu & Wang, 2011; ISO, 1998; Joma, 2009; Kawasaki, 2004).

The mainstream on our research in this paper classified success factors into five main categories, i.e. technology acceptance factors, social factors, cognitive factors, ethical factors and environmental factors.

Firstly, technology acceptance factors are mainly focused on the websites, including website quality and website design. Majority of the work identified information quality and system quality as the two main factors to reflect website quality (Cebi, 2013; Chen & Chou, 2012). Some work extended the website quality to also include service quality (Clements, Dean & Cohen, 2009). Originally, five dimensions were defined for physical marketplace service quality: tangibles, reliability, responsiveness, assurance and empathy (Kawasaki, 2004). In e-commerce context, methods of measuring success differ from physical marketplace service. E-service quality is therefore defined as the overall customer assessment and judgment of e-service delivery in the virtual marketplace (Clements, Dean & Cohen, 2009). Website design

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

factors have been diverse; they range from usability and usefulness to interactivity and explicitly (Joma, 2009). Among which, usability is probably the widely discussed factor. For example, does the website have a good structured navigation system for customers to explore the website contents and easily find their desired products or services? Of course, website design and website quality are closely related to each other. Some authors have suggested that website design, fulfilment/ reliability, privacy/ security and customer services are the determinants of customer judgments of quality and satisfaction, customer loyalty and attitudes towards a company's online business (Lee & Kozar, 2006).

In terms of social factors, those on the top of the list include the sense of virtual community, and the use of social media in online shopping, for example, in the luxury online shopping (Fang, Chiu & Wang, 2011). Online shoppers use blogs, customer reviews etc. to help their purchase decisions. By interacting with other customers, online shoppers feel a strong sense of community and gain satisfaction from others' feedback on the products or services that an online shop provides. Some shoppers think that peer-customers' words are more trustworthy than what specialists' marketing pitches (Lee & Lin, 2005).

Many other authors have, however, identified trust as an ethical factor. Trust perhaps has been one of the most discussed factors and that is why it spans across both social and ethical categories (Machado, 2011; Ngai, 2003). No matter to which category should trust belong, the basic meanings of trust in the e-commerce context are almost the same, i.e. about practicing privacy policies, describing products and services online objectively and honestly, and maintain transparency of the online business operations (Nielsen, 1994). Some research has even investigated the relationship between knowledge and trust and found a positive relationship between them. Therefore, a suggestion is made that online retailing practice should make the public more knowledgeable e.g. about the online transaction security mechanisms in order to build up user's trust in online shopping (Olson & Boyer, 2005).

Environmental factors to ensure e-commerce success have not been discussed as widely as the other four categories. Only recently, a research on e-commerce trends and development to enhance online customer's satisfaction in China observed three important environmental success factors: government regulations, payment systems, and logistics systems (O'Reilly & Marx, 2011).

Another interesting classification of success factors is based on the process stages of online shopping. It seems that most research in the context of B2C context agrees on a four-stage process model for online shopping: information, agreement, settlement, and after-sale stages (ISO, 1998; Parasuraman, Zeithaml & Berry, 1988). A process model for C2C e-commerce (online auction) defined the four stages as information, communication, distribution and transaction (Shahabuddin, 2010). New critical success factors developed in the process models include trade safety, governance and order, reputation and scale, communication channel, information search, transaction process and copious information.

A third classification scheme is more generic, which only have two categories of success factors: customer-centric factors and website-centric factors (Duncan, 2011). The work based on the case of Japan finds out that customers are more concerned about the customer – centric factors, especially customer's education level, creativity, and net-orientation. It seems that Japanese customers do not worry about that much about e-service quality, which is a key success factor in the website-centric category.

Based on the above comprehensive review on literature, it is evident that there have been a huge number of success factors for e-commerce being defined, and that those factors are often discussed in isolation or from a particular perspective, which limits the contribution of existing work to online shop design and implementation practice. E-commerce is a complex e-business process, which requires knowledge from multiple disciplines to make it successful. Therefore, there is a clear need to develop a more advanced framework that can integrate critical success factors from multiple perspectives for

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

online shopping. It is expected that such a multi-perspective integrated framework can provide effective guidance to e-commerce provider's design and implementation of successful online stores, as referred in (Burgess, 2008).

4. ONLINE SHOPPING CRITICAL SUCCESS FACTORS

E-commerce is undoubtedly the future that most companies will have to face. However, the fact of creating an online store does not mean guaranteed success.

E-commerce presents fresh challenges that set around a multidisciplinary environment and that must be in harmony, as there are complementary aspects arising from each area, which have to be considered and integrated, as a requirement for success (Torkzadeh & Dhillon, 2002; Suntornpithug, Todorovic, & Sherrell, 2010).

Just like a real physical shop, also in e-commerce it is not just the commercial part that is implied but a whole set of assumptions that must be guaranteed and controlled. The internet is a medium with its own characteristics, where every detail must be thought out carefully so that the final result is as expected.

Burgess (2008) proposed a multi-perspective model (MPCSF) for critical success factors, which is the base model used in this paper for carrying out a study of critical success factors, included in the MPCSF model that have been considered in an integrated and summarized manner, in the context of online shopping and corresponding websites analysis. The authors of this paper (Burgess, 2008) believe that all the success factors should be considered simultaneously from multiple perspectives (technological perspective such as web design usability, social perspective such as social networks, etc.), across different e-commerce life cycle stages (e.g. pre-sale, information stage and supply chain). Their proposed interdisciplinary model includes branding and marketing in Business Management discipline; communication support in Technology and Engineering discipline; and quality data processing in Science discipline. After it is combined with the classification schemes discussed earlier in Section 2 (i.e. customer-centric and website-centric, and process-based classification).

As stated in (Burgess, 2008), the concept of e-commerce can be viewed as being similar to the solar system, where the e-commerce is the central star and it must include on its orbit all the other stars. Once one of the surrounding stars disappears from its orbit the whole system's stability can be checkmated. Whether for lack of credibility, poor branding concept or simply due to a poor visibility, any failure on one of the factors implies that the project may not work properly and there are plenty of online stores that just do not sell (Burgess, 2008). Next, a summarized view of over an aggregated set of 8 main critical success factors, based on the detailed list of critical success factors described in (Varela et al, 2016) is presented.

4.1. Payment Security

With the exponential growth of the Internet shopping, security has been the major concern of users. However, increasingly more money transactions take place and the systems are becoming considerably safer. Selecting safe payment methods and be at the forefront of information technology about security issues, is a competitive advantage on online selling. Thus, if the client is aware about the online shop concerns to ensure secure payment transactions, the brighter the image of trust and responsibility will be passed to potential clients.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Although the world is aware that issues about security breaches continue to rise on data computing and Internet transactions, and as even the most protected systems are transposable, we must maintain the dedication to guarantee purchases as much secure as possible. Moreover, to attract online customers e-commerce business should understand the customers' real wishes and expectations and what payment methods each type of segment of users does prefer. Each marketplace has its peculiarities and consumers tend to create common purchasing habits with which they feel more comfortable, e.g. "to use the online shopping cart" (Thorleuchter & Van Den Poel, 2012).

4.2. Website Userfriendliness

Websites user-friendliness is nowadays a growing exigency of customers, as social networks have changed the way people communicate, enabling to reinvent something we did naturally, with a slower speed. The initial idea was aimed at friends to join on a virtual network where they could communicate about everyday's life. This phenomenon has exceeded expectations and inevitably began to move towards the business world. If customers are concentrated on a particular community, nothing is more natural than participating on it.

Nowadays, all major brands present themselves within this environment, trying to reach a huge market with a multiplying growing effect (Suntornpithug, Todorovic & Sherrell, 2010). Applying the phenomenon of social networks to e-commerce, has the additional advantage of reaching people that are already regular users of the Internet, and to capture their attention to new products and services requires a good communication and marketing strategies to be implemented. Thus, one can gain customers through these communication engines, enhancing the target market.

Another important aspect of websites' user-friendliness relies on the underlying website's usability. In an online, shop the customer interface occurs via the website, therefore, their expectations have to be met as they easily may move away to the competition. Therefore, one crucial issue on the design of any information system is the usability of the user's interface. According to ISO 9241 - Part 11 (1998) usability is defined as the effectiveness, efficiency and satisfaction with which specific users achieve goals in particular environments. These definitions relate directly with 3 questions: How can users perform their tasks? What resources must users spend to achieve a given outcome (e.g., time, effort)? How well do users like the application?

Besides the economical costs (i.e. a system that is hard to understand is also hard to sell, and may involve many expensive problems in its life cycle), the lack of care about users needs can lead to solutions that tend to cause errors or that provide users with inadequate information. For e-commerce, this is particularly harmful because it implies losing customers (Thorleuchter & Van Den Poel, 2012).

Usability is an essential critical success factor to take in consideration in the design of websites because it is not a single, one-dimensional property of a user interface. Usability has multiple components and is traditionally associated with five usability attributes: learnability, efficiency, memorability, errors, and satisfaction (Tu, Yen & Hou, 2010).

4.3. Business Brand and Confidence

Knowing our business can help to know, "where we are" and "where we want to go" (Alturas, Santos & Brites, 2006). Measuring performance at each step of business allows adjusting measures to consider and values to obtain, through a sustained growth. This measurement is only possible if there are pre-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

defined and measurable goals for market trends. Therefore, it is necessary to know if it is a marketplace of thousands, millions or billions.

The more information available the better our position will be to support good decision making strategies. Understanding the marketplace is the first step, setting goals is the second one and nothing serves the former if there is no continuous analysis of results obtained.

In order to completely fulfil the whole requirements inherent to a successful business, it is of upmost importance to know the world of brands, as it moves millions, as increasingly more companies look for convincing brands, to better affirm themselves among competitors (Suntornpithug, Todorovic & Sherrell, 2010). In e-commerce the paradigm does not change, to buy online, you need something to push you to finalize your purchase. It is not enough to think that a brand is just a cute name or a futuristic logo, the whole communication with the surroundings has to be well thought, and the care and concern about the customers need to be visible in order to enable to construct a loyalty based relation with them (Suntornpithug, Todorovic & Sherrell, 2010).

The concept of a brand has to have the objective to be a precise way to reach the clients and establish a collaborative interaction with them by enabling integration of different areas. Impact, desire and trust are the ingredients that may enable a common brand to become a benchmark worldwide. If the main purpose of the brand is not describable by a few words, it is most probably not well designed.

4.4. Website Effectiveness

Regarding expectations of users to find the products they are looking for website's effectiveness plays a crucial role because once achieved the complete flow of the market to the online shop, there is still another important but less explored subject, which consists on being able to convert a visitor into a customer (Tsai, Cheng & Chen, 2011).

With the tools available on the market it is possible to analyze many details about visits to a website. From the time each user wastes browsing, up to the number of visitors per day, broken down by country and other indicators, many different kind of analysis are possible.

When the number of visits to a website is big and the sales have not risen, something must be done to reverse potential customer's bad attention. Issues related to websites effectiveness and usability, communication and marketing problems must be completely revised to ensure e-commerce success.

4.5. Marketing Strategy

Using an appropriate marketing strategy along with an improved business offered and other non-technological areas are crucial multidisciplinary requirements for the success of e-commerce. Moreover, once a brand is defined – and this applies to any product - it needs to be recognized as a reference. A well structured marketing plan, with a well-defined line and an innovative and credible image are essential success factors for promoting any brand or product (Alturas, Santos & Brites, 2006).

From videos and images up to workshops and international conferences, it is worth using all channels of communication to solidify the brand on the market. Thus, it becomes a necessity to innovate and to re-invent the way we present ourselves to the world (Wolfinbarger & Gilly, 2003).

Although a segment of the Marketing, the Web- Marketing deserves special mention, for conceiving a fantastic store, in terms of design and image, may seem to be good enough for becoming very success-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ful. However, imagine how disastrous it would be if no one would pass on the street where the shop is located and the same may happen regarding online stores (http://www.acepi.pt).

Search engines provide the initial dialogue between consumers and online stores; therefore a good positioning or ranking of a website is of utmost importance. Search engines, like Google, also have tools to measure how many times certain words are searched and analyze all statistical data about the number of visitors about a given online store. Hence, improving search strategies is another important success factor.

There are several ways for enabling good rankings of websites within searching engines, which turns out to be even more important when a website includes sponsored links. The best way to attract potential customers is to accurately know the market where it operates, so that the whole effort is focused in favour of the business (Suntornpithug, Todorovic & Sherrell, 2010).

4.6. After-Sales Support Service

When buying on an online store, its success is only possible if there is a satisfactory level of communication support along the entire supply chain, which must be synchronized and integrated (Wu, Tao & Wang, 2007). A climate of trust and sharing must prevail, so that the whole quality of the system is reflected on the final consumer (Yuen, 2010).

If the manufacturer and all intermediaries are not sharing the same values, the whole communication within the supply chain may be compromised and the concept of a successful online store will most probably fall. Imagine how disastrous it would be having a well-designed online store, with a powerful marketing and numerous customers and the delivery due dates of the products were constantly being violated (O'Brien, 2015).

Only the skilled ones can be a part of the successful communication and supply chain, for each one, on its "core business", to provide its best possible contribution, always focused on reaching integration and common objectives and customer satisfaction.

The clients and their satisfaction must be constant concerns of any company aspiring to reach a sustainable growth (Torkzadeh & Dhillon, 2002). Moreover, in a medium like the internet, additional concerns about the fact that many users still do not feel comfortable buying products they cannot physically see, have to be kept on mind. One central concern of a consumer is about knowing if the website provides support to clarify questions about products or services; and, in particular, issues related to product returns or simply about how to get more direct information about the provided products and/ or services. With the growth of the Internet there are also many online shops whose quality standards do not meet customer requirements, installing uncertainty on the marketplace.

It is of utmost importance to provide a full-service support, before, during and after purchase. This way the clients feel supported and understood and not afraid to repeat the experience and buy through the same website.

The word "guarantee" frightens many entrepreneurs; however, this paradigm must change as people buy more if they feel fully supported and "safe" and in the majority of online stores the rates about product returns are quite low company aspiring to reach a sustainable growth (Torkzadeh & Dhillon, 2002).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.7. Company's Credibility

Regarding marketing strategies to incentivize anyone to buy through an online store, there are still many entrepreneurs targeting cost reduction instead of investing on that direction to enrich online stores' credibility. A shop with an "amateur" aspect easily distracts consumers that are more already suspicious about online shopping.

A good call centre, setting up a company with physical office, a registered trademark and the overall design and functionality of the website should not be jeopardized due to a low budget. Moreover, being professional and combining all these details will help strengthen the credibility of the store. Another key factor consists on joining forces and partnering with credible companies (Wu, Tao & Wang, 2007).

The overall credibility of an online store is visible when it is working perfectly, without any bugs or links that do not work. When usability is jeopardized and something stops working and confuses the user this may compromise the quality of the whole website and the underlying information system project, along with the correct functioning of the communication channels and the underlying operation of the supply chain, which is essential to gain the users confidence.

Moreover, the quality of the delivered product and/or services can be compromised while lacking quality data processing, therefore, it is also of upmost importance to ensure quality data processing (Schubert, 2002).

4.8. General Website Quality

The website is a showcase of the online store, which has to take into account to whom it should attract attention, as its mere existence does not mean its success. The whole construction of the website must be developed by a multidisciplinary team because there are several areas that will be involved for achieving the final product with the intended image and functionality. For example: the programmer may build the website quite clearly, without any bugs or technical problems, but if the designer does not provide an efficient interface it probably will fail (Schubert, 2002).

Therefore, all those multidisciplinary areas should be taken in consideration on the creation of any website, so that each area can provide an important contribution to its final result. Any successful e-commerce website must be robust, complete, appealing and balanced to ensure passing an image of a serious and credible company, without any tendentious reflection just about a particular area or concern.

The next section presents the study undertaken and analyses the impact of these main critical success factors on existing websites.

5. DATA ANALYSIS AND DISCUSSION

In this study 12 websites (WS1 to WS12) about luxurious furniture, were analysed in order to understand the set of 8 main characteristics on these websites. These 8 main critical success factors (CSF1 to CSF8), are given utmost importance, for evaluating websites, according to the description previously presented. Table 1 provides a list of the 12 websites and the corresponding links.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 1. Websites analyzed

WS number	Website link
WS1	http://www.bernadettelivingston.com/
WS2	http://www.williams-sonoma.com/
WS3	http://www.juliettesinteriors.co.uk/
WS4	http://www.taylorllorentefurniture.com/
WS5	http://www.horchow.com/
WS6	http://www.luxuryfurnitureandlighting.com/
WS7	http://www.scalaluxury.com/
WS8	https://www.savannahcollections.com/
WS9	http://www.ikandi-interiors.com.uk/
WS10	http://www.greenfront.com/
WS11	http://www.furniture.mj777.com/index_en.htm
WS12	http://www.ramobili.it/

The 8 main critical success factors (CSF) that were analysed along the 12 websites are:

CSF1) Payments security
CSF2) Website user friendliness
CSF3) Business brand and confidence
CSF4) Website effectiveness
CSF5) Marketing strategy
CSF6) After-sales support service
CSF7) Company's credibility
CSF8) General website quality

In this study, a set of 70 qualified users on systems analysis were inquired, about each of the 8 main CSFs, for being evaluated on the 12 websites referred above, on a range from 0 to 3, as follows:

0 – the CSF is not applied
1 – the CSF is fairly applied or satisfied
2 – the CSF is suitably applied or satisfied
3 – the CSF is completely applied or satisfied

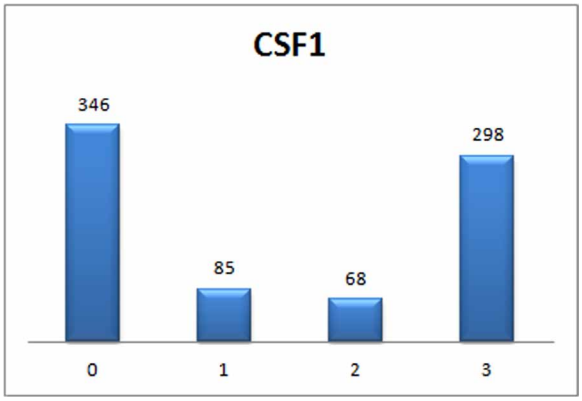
The results obtained for each CSF are presented in the next sections. The evaluations attributed to each CSF by the inquired individuals in a range varying from 0 to 3 points, are graphically represented in the following eight graphics.

5.1. Payments Security

The results obtained for the payment security critical success factor (CSF1) are shown in Figure 1.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. Payment security results (CSF1)



As we can realize through the results presented on Figure 1, for this CSF1, about payment security, around 43.4% of the answers reveal that payment security is not applied; 10.7% of the answers reveal that it is fairly applied or satisfied; 8.5% of the answers reveal that it is suitably applied or satisfied; and 37.4% of the answers reveal that it is completely applied or satisfied.

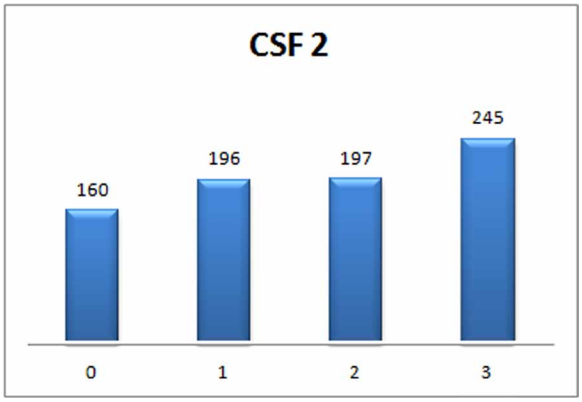
According to the results obtained we may realize that payment security is a CSF that is not always clearly satisfied, which can drastically penalize online stores.

5.2. Website User-friendlyness

The results obtained for the website user-friendliness critical success factor (CSF2) are shown in Figure 2.

As we can realize through the results presented on Figure 2, for this CSF2, about website user-friendliness, around 20.0% of the answers reveal that website user-friendliness is not existing; 24.6% of the answers reveal that it is fairly existing; 24.7% of the answers reveal that it is suitably existing; and 30.7% of the answers reveal that it is completely existing or satisfied.

Figure 2. Website user-friendliness (CSF2)



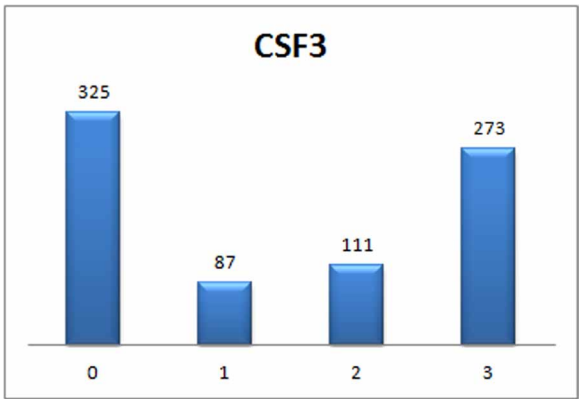
EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

According to the results obtained we may realize that although we can notice a good strength regarding website user-friendliness improvement is a CSF that is not always clearly satisfied, which can punish online stores.

5.3. Business Brand and Confidence

The results obtained for the business brand and confidence critical success factor (CSF3) are shown in Figure 3.

Figure 3. Business brand and confidence (CSF3)



As we can realize through the results presented on Figure 3, for this CSF3, about business brand and confidence, around 40.8% of the answers reveal that business brand and confidence is not existing or satisfied; 10.9% of the answers reveal that it is fairly existing or satisfied; 13.9% of the answers reveal that it is suitably existing or satisfied; and 34.4% of the answers reveal that it is completely existing or satisfied.

According to the results obtained we may realize that business brand and confidence is a CSF that does not always undoubtedly exist, which can severely reprimand online shopping.

5.4. Website Effectiveness

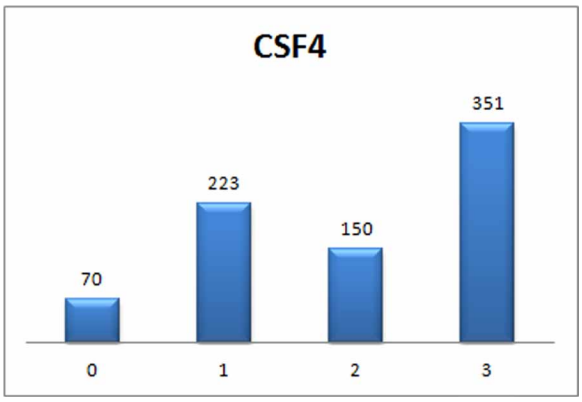
The results obtained for the website effectiveness critical success factor (CSF4) are shown in Figure 4.

As we can realize through the results presented on Figure 4, for this CSF4, about website effectiveness, around 8.8% of the answers reveal that website effectiveness does not exist or satisfied; 28.1% of the answers reveal that it is fairly existing or satisfied; 18.9% of the answers reveal that it is suitably existing or satisfied; and 44.2% of the answers reveal that it is completely existing or satisfied.

According to the results obtained we may realize that website effectiveness is a CSF that does seem, in general, to be quite acceptably satisfied, which reveals a growing effort taken in the direction of persuading potential clients to buy online.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

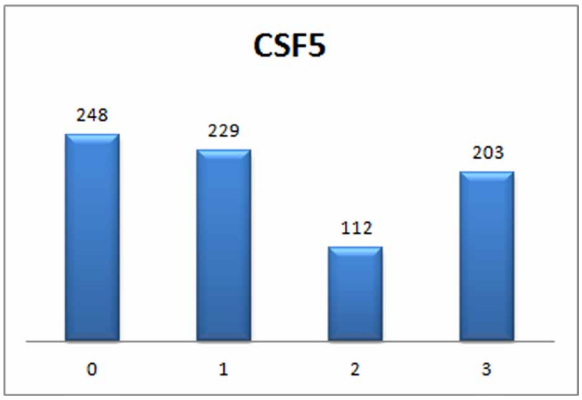
Figure 4. Website effectiveness (CSF4)



5.5. Marketing Strategy

The results obtained for the marketing strategy critical success factor (CSF5) are shown in Figure 5.

Figure 5. Marketing strategy (CSF5)



As we can realize through the results presented on Figure 5, for this CSF5, about marketing strategy, around 31.3% of the answers reveal that marketing strategy is not applied or visible; 28.9% of the answers reveal that it is fairly applied; 14.2% of the answers reveal that it is suitably applied or satisfied; and 25.6% of the answers reveal that it is completely applied or satisfied.

According to the results obtained we may realize that although we can notice a good strength regarding market strategy concerns is a CSF that is not always clearly satisfied, which can negatively affect online stores.

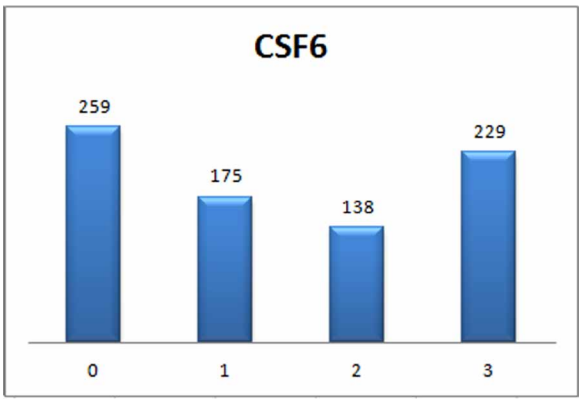
5.6. After-Sales Support Service

The results obtained for the after-sales service critical success factor (CSF6) are shown in Figure 6.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

As we can realize through the results presented on Figure 6, for this CSF6, about after-sales service, around 32.3% of the answers reveal that after-sales support service does not exist; 21.9% of the answers reveal that it is fairly existing; 17.2% of the answers reveal that it is suitably implemented; and 28.6% of the answers reveal that it is fully implemented.

Figure 6. After-sales support service (CSF6)

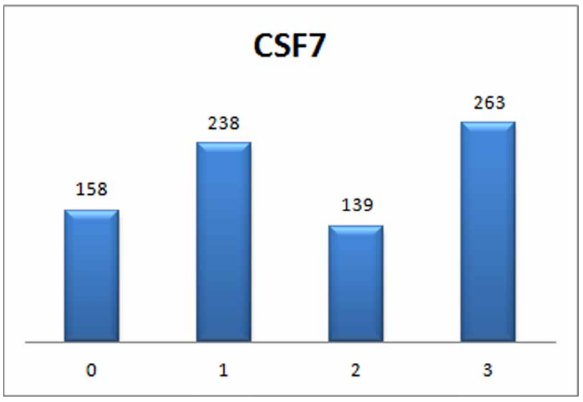


According to the results obtained we may realize that after-sales support service is a CSF that does not always clearly exist, which can penalize the success of online stores.

5.7. Company's Credibility

The results obtained for the company's credibility critical success factor (CSF7) are shown in Figure 7.

Figure 7. Company's credibility (CSF7)



As we can realize through the results presented on Figure 7, for this CSF7, about company's credibility, around 19.8% of the answers reveal that company's credibility is not visible; 29.8% of the answers

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

reveal that it is fairly visible; 17.4% of the answers reveal that it is suitably visible; and 33.0% of the answers reveal that it is completely noticeable.

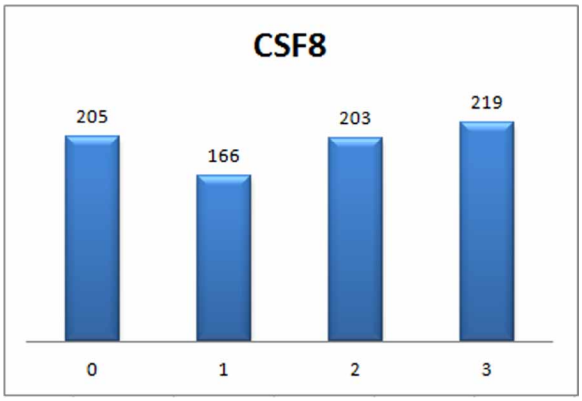
According to the results obtained we may realize that company's credibility is a CSF that does seems, in general, to be a concern of companies for being satisfied, in order to attract potential clients to buy online.

5.8. General Website Quality

The results obtained for the general website quality critical success factor (CSF8) are shown in Figure 8.

As we can realize through the results presented on Figure 8, for this CSF8, about the general website quality, around 25.9% of the answers reveal that general website quality is very poor; 20.8% of the answers reveal that it is fairly satisfactory; 26.6% of the answers reveal that it is good; and 27.6% of the answers reveal that it is excellent.

Figure 8. General website quality (CSF8)



According to the results obtained we may realize that general website quality is a CSF that appears to be a concern of companies. Although a growing effort has to be taken in this direction to improve quality of online shopping services.

6. CONCLUSION

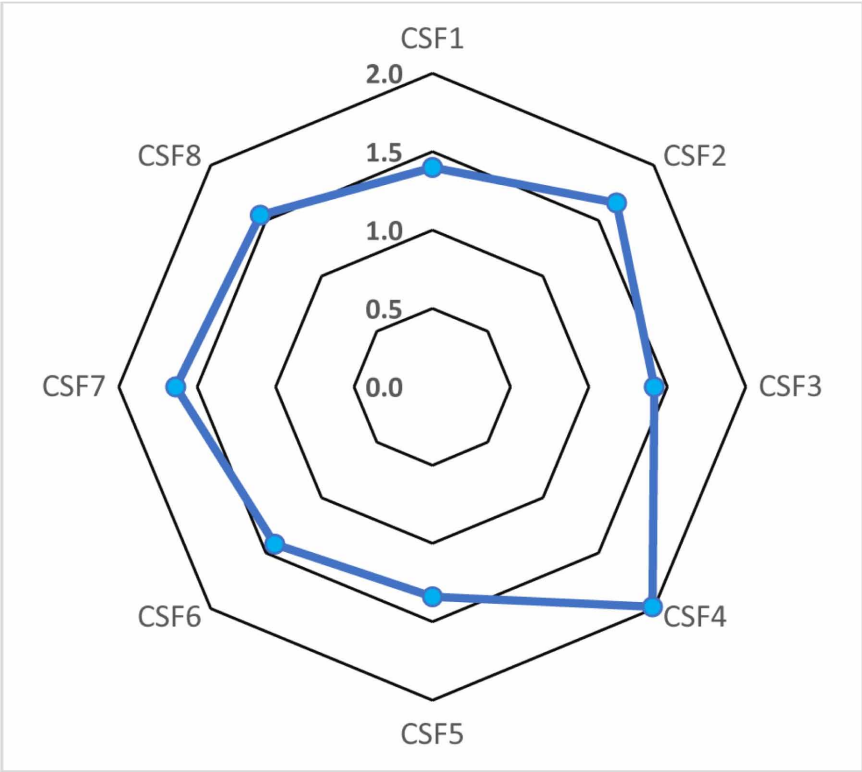
As represented in the overall representation of Figure 9, the critical success factor "Website effectiveness" is the only one presenting a graduation of suitably satisfied (1.99), and the worse ranked are "Marketing strategy" (1.34) and "Payment security results" (1.40).

Knowing the necessary ingredients for success in e-commerce is crucial to build a highly profitable and consistent e-commerce business strategy. Building an online shop based on a fully satisfied critical success factors will enable a successful online business and transmit confidence to potential online clients.

Therefore, it is of upmost importance not to distract customers, while compromising the balance of a whole website. There is still plenty of room for improvement in the market of online shops, as more

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 9. Weighted average evaluation for the eight CSF



and more people choose this way of shopping, which enables entrepreneurs to get closer to its market, while presenting an appropriate solution for their clients' expectations. Moreover, it is necessary to pay attention to aspects for enabling a good e-commerce practice. Often those aspects are under estimated due to lack of analysis and investigation regarding a set of proposed success factors described through this work.

The proposed set of main critical success factors described and analysed in this paper are not only related to the website itself, its design and usability, but also to other considered very important ones, such as: the brand; the marketing and web-marketing strategies; including social networks reaching; concerns about the whole supply chain integration; concerns regarding consumers conversion, communication and support; looking at quality data processing and secure payment methods; and enabling a favourable image for reaching online shop credibility. Compared with existing conceptual models for e-commerce success factors in the literature, there are some relevant contributions of our proposal, including: The definition of proposed critical success factors such as converting customers and credibility; the proposal to include stages beyond the existing online shopping life cycle, i.e. it considering not only the information phase, agreement phase, transaction phase and delivery phase, but also the pre- and after-sale phases; also incorporating the critical success factors from multiple perspectives – technology, social and ethical perspective; and integrating knowledge from multiple disciplines such as Engineering, Science and Technology, and Business Management. Therefore, the proposed critical success factors can provide a more comprehensive understanding of online shopping in order to achieve business success.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

In addition, it has been identified that a more professional attitude is needed, as all these factors are of major importance for ensuring the difference between a modest online store and an online empire.

ACKNOWLEDGMENT

Chapter 26
Exploring the Factors Influencing Customers Purchase Intention in Online Shopping

Fahima Khanam
University of Dhaka, Dhaka, Bangladesh

ABSTRACT

Online shopping has increasingly become popular in Bangladesh with the introduction of globalization. Many people, specifically the younger generation, are purchasing various types of products every day online as it is convenient and saves time. Consumers are influenced to purchase online as a result of many factors including time-savings, fast delivery, ease of the transaction, and a website's user friendliness, and many more. The consumer evaluation is important to explore why a consumer intends to purchase online. The present study is an attempt to determine the factors that influence consumers' online shopping in Dhaka. Through this process, this study attempts to identify the critical factors that influence consumers' online shopping in Dhaka and to evaluate the association between these factors and consumers' online shopping habits. It also tries to determine the importance of these factors on consumers' online purchasing habits and to identify problems and suggest possible recommendations. The factors that are being considered include convenience factors, psychological factors, promotional factors, technical factors, and motivational factors. Each factor has some distinct variables. Convenience factors include less time, home delivery, and ease of transaction. Psychological factors include domain specific innovativeness, and opinion of friends and peers. Promotional factors include online ads, and social media exposure. Technical factors include user-friendliness of websites, and display of product details. Motivational factors encompass utilitarian and hedonic values. For this study the Multiple Regression Analysis Model was used. A structured questionnaire survey was conducted on 120 consumers to obtain consumers' opinion regarding how their purchase habits are sparked by different factors. The results reveal that only the home delivery system and utilitarian value of online shopping makes customers consider purchasing online. The other important influences were opinion of friend and peers, social media exposure, and display of product details. This study can hopefully shed some new insights into consumers' online purchasing habits.

INTRODUCTION

Since the advent of science and modern technology (Schlesinger and Rahman, 2015), a parallel world has been taking a form which may be called 'the virtual world'. Today it is not merely forming, rather it is extraordinarily enriched. People now possess two lives at the same time. One is the real human life and the other is virtual life. It would seem like they are more into the latter one. Internet has given a new life to almost half the population of the whole world. This new life has started from the countless options that the internet has given to us through its astonishing ability to connect the north hemisphere with the south hemisphere. The internet created so many new trends that have become the inseparable parts of human life. Without them our lives cannot even be imagined today. Some of the, influences include E-mail, online entertainment, social media, online shopping and search engine browsing.

Among these trends, online shopping has become a new option for the consumers. Today a good number of organizations have their online sales option. Beside brick-and-mortar, numerous companies are showing up as click-only. These are offering consumers a wide range of products from clothes to books to even cars. Advancement of technology has given people the opportunities to connect to the internet anytime through more than one device including desktops, laptops, smart phones, and tablets (Akhter et al., 2014). Online shopping has opened a new horizon for entrepreneurs. Internet has become a great means for them to sell their products to customers anywhere. There are obviously a lot of drawbacks for offline shopping. Numerous research studies were conducted on the comparison of these two extremes. Nevertheless, online shopping has also many advantages for customers to consider.

The use of online shopping is new to Bangladesh due to the protocol of Bangladesh government, it has become much easier for the businesses and customers to take part. It has a growing market of 2 billion BDT. The introduction of 3G sped up the growth of the online retail industry significantly. "There are a number of free classified websites and online shopping marketplaces in Bangladesh that sell almost all types of goods and services. For example, Othoba.com, Ekhanei.com, Bikroy.com, 'Lamudi', 'Carmudi' and 'Kaymu'." (E-Commerce Directory, 2014). "About 1.5 to 2 million people shopped online every year, and the market was growing by 15% to 20%." (Shah, 2014).

By definition, online shopping takes place through websites over the internet. Generally online retailers can be categorized in two types: click-and-mortar and click only. The click-and-mortars are those firms that have both physical stores and online channels. These firms generally started their business physically as click and motor and when online business concept showed up, they simply adopted the new idea and created a new communication and distribution channel over the internet. On the contrary, clicks-only are those firms that only have online presence. It is clear that these firms initiated their businesses online. However, sometimes clicks-only also open their physical stores. In Bangladesh, most of the clicks-only are online superstores. They sell variety of products of different brands. Examples are daraaz.com, kaymu.bd, bagdoom.com. All of them offer different products of different brands such as, men's wear, women's wear, shoes, cosmetics, watches, bags, toys, and electronics. International online stores also operate in Bangladesh. A big example is Amazon.com which first started selling books and is now one of the world's biggest business giants as a retailer of various kinds of products. Some online shops are specialty stores also. For example, some sell only saree, some sell only 'kameez' and some sell only books. A notable example can be rokomari.com that earned its huge reputation and revenue also by selling books. However, recently it has started offering electronics and other home products. There are also some Facebook-based retailers such as He & She, 'Rongoboti,' etc. Generally, the Facebook-based online stores happen to be specialty stores such as, He & She sells jewelry and Rongoboti sells cosmet-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ics. Again, the online retailers operating through their own websites also maintain their Facebook pages through which they sell products using Facebook-authorized button "Shop Now".

Now-a-days, online shopping can be performed on personal computers and mobile phones. The development of mobile phone technology has given the consumers the facility to order goods from literally anywhere anytime (Rahman et al., 2014). The development of mobile-optimized web services gave marketers the competitive edge over those who did not introduce mobile optimization. This technology has enabled web developers to create a mobile version of a website. The mobile version takes less space eliminating unnecessary formatting and layout of the original version of the website and displaying limited advertisements. This mobile version also makes sure that the consumers can easily navigate through the website and choose their products, view the specifications, and finally order them with the help of touching the screen. Above all, the era of smart phones compelled the marketers to give consumers easier experience on tiny mobile screens compared to the large computer monitors. Besides, traditionally consumers use desktops and laptops to access online shops and order their products. However, day by day consumers are leaning more toward mobile phones than personal computers. The reason might be the mobility of the device that lets consumers use their spare time on shopping while sitting in a traffic jam or waiting for a meeting.

On personal computers, a consumer generally enters into the website of the particular retailer. These websites naturally categorize the types of products in their menu bar. The consumer then goes to his desired product section. A desired product section again has more than one category such as, price range, brand etc. The consumer chooses a certain category according to his needs and abilities. Then the products' images show up on the webpage. Almost all the retailers keep more than one type of a particular product based on its color, size and other features. If the consumer clicks a certain product image, he is redirected to a webpage that contains all the specifications of and relevant information about the product. Generally, most of the consumers pause here and revert to the product category again. They compare the specifications and images with other types of that product. Sometimes, consumers revert more and go to the main category section and compare the product quality of different prices. Even sometimes they open new tabs to visit other online retailers' websites and compare its price, quality or specifications with those of the previously visited ones. When a consumer finally chooses a particular product and gets determined to order it, he hovers over the 'Buy now' or 'Shop now' button to order. Once he clicks it, he has to register with the website if previously not done and then log into the site with his newly made official account. This official account is required to proceed to the payment method and delivery. Sometimes, order is taken over telephone with recording consumer tracking numbers or accounts. The payment method can be of many types such as, cash-on-delivery, mobile banking, or credit card. Cash-on-delivery is the system in which the payment is made with cash to the delivery man at the time of product delivery. Cash-on-delivery is a widely trusted payment method that allows users to test the product at the time of delivery and return order if any problem is noticed. The delivery of product can also be in many forms, such as delivery man, using parcel services, courier, lifting from the nearby both of the company etc.

All these steps are similar in case of shopping on mobile phones. Now-a-days, many retailers are introducing their own apps for the consumers to install them into their phones and order products more easily by simply tapping the respective icon and order accordingly. In this case consumers do not need to open the browser and typing the website address and follow other procedures. The online retailers also introduced the concept of 'shopping list' or 'shopping cart' by which a consumer can easily list his desired products to order later at a time.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Shopping in Facebook pages also requires the same procedures. In this case one advantage is that consumers can take part in conversations with other consumers to know better about the quality of products. The number of likes of a particular product also indicates the favorability of that product to the consumers. All these things prepare a field for the consumer to make a purchasing decision. Sometimes Facebook pages are considered to be negative. An example of this is when consumers raise their voices against a particular product to express their dissatisfaction with the product or service. This results in the retailer losing many consumers who will more than likely never visit this shop ever again. Selling through Facebook pages reaches a lot more customers than does own websites. But in the former case, the marketer has to maintain the word-of-mouth to flow in a positive and healthy manner.

This study is an overview of online shopping which will examine its various aspects and try to measure the effects of several factors on people choosing online shopping.

BACKGROUND OF THE STUDY

The ability to bring the outer world on the nose of the users can be considered as the biggest contribution of the internet. Whatever happens in the universe can easily come to people sitting at their computers at Dhaka, Delhi, Texas or Cairo. The latest addition to this phenomenon is to enable people to choose their things sitting at their home not going to the physical shops down the lane. That is how people get started purchasing things online. At the beginning of the online shopping era, only young people were into online shopping. But recent statistics show that people of all ages are being accustomed to online shopping. Online shopping took people of all ages by storm. Depending on this craze, numerous online retailers have lifted their heads up. They are getting customers too. Here the biggest question is that which aspects of online shopping are liked by people and which are not. It is evident that neither all aspects of online shopping are liked by people nor all the customers are evenly patronizing it. A good number of studies have been conducted on investigating the effects of different factors of online shopping on customers and on investigating how factors of online shopping influence the intention, attitude and behavior of customers. However, no specific studies are found on the effect of factors on consumers purchasing online in the context of Dhaka. This study will try to investigate which specific factors influence consumers to purchase things online in Dhaka, Bangladesh. The possible factors were extracted from the analysis of some related literature.

LITERATURE REVIEW

In a study on analysis of factors affecting online shopping behavior based on Iran, Javadi et al. (2012) categorized some risk factors under "perceived risks" that influence consumers' online shopping behavior. These risks are financial risk, product risk, convenience risk and non-delivery risk. Among these, according to the study, the effects of product and convenience risks are not significant on attitude toward online shopping. Results furthermore indicated that infrastructural variables (after sales service, cyber laws and shipping fees) and return policy were not significant either. However, the results showed significant influence of domain specific innovativeness and opinion of friends and peers on online shopping behavior. Strong relationship between opinion of friends and peers and purchase intention was also supported by another study covering the mediating role of online purchase intention (Lim et. al., 2016).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

This study also supported the low significance of product risks. It found out that usefulness of products had weak relationship with online purchase intention.

Another study (Forsythe and Shi, 2003) provides a completely opposite result in case of product risks and convenience risks. According to this study, these two risks are very significant on consumers' frequency of purchasing online. This study also examines another risk called psychological risk, the effect of which is not significant on consumers.

A study on online shopping behavior of consumers (Uzun and Poturak, 2014) concluded that price is the most important factor for consumers to purchase online. The study concluded that consumers' future buying is not affected by web design and delivery time rather by last experience. This study also declared the convenience of products as one of the most influencing factors to satisfy consumers.

An interesting insight was found in a study on e-commerce factors influencing consumers' buying decision (Baubonienė and Gulevičiūtė, 2015). According to this study lower price is more valued by women, whereas time and convenience are more important to men. The study also concluded that 25–34-year-old people more often chose online shops because of lower prices and greater variety of products.

Another study covering the same area (Akbar and James, 2014) categorized the factors of online shopping under three stages, information search stage, alternative evaluation stage and purchase decision stage. The result indicated that price, brand and convenience under the alternative evaluation stage strongly influence online purchase behavior. Under the purchase decision stage, security and refund had a moderate effect and promotion had a weak effect on online purchasing.

A study on the same area based on Kolkata (Sen, 2014) concluded that cost factor was the most significant factor to influence online purchase decision. It suggested that price reduction, offer, discount and sales promotional techniques positively influence online purchase decision. After cost, it put importance on convenience factors such as time, secure payment, cash on delivery and product information. It declared the seller related factors as the least significant factors to influence online purchase decision.

A different perspective was examined by a study (Topaloglu, 2012) covering consumer motivation and concern factors for online shopping in Turkey. It identified two broad factors, namely, motivation factors and concern factors, to examine whether they influence online search and purchase intention. Motivation factors included utilitarian value and hedonic value. On the other hand, concern factors included privacy and security.

CONCEPTUAL FRAMEWORK

Based on the above-mentioned studies conducted previously, five types of very important factors can be identified. These factors are convenience factors, psychological factors, promotional factors, technical factors, and motivational factors. Each factor has some distinct variables. Convenience factors include less time, home delivery, and ease of transaction. Psychological factors include domain specific innovativeness, and opinion of friends and peers. Promotional factors include online ads, and social media exposure. Technical factors include user-friendliness of websites, and display of product details. Motivational factors include utilitarian and hedonic values. How these variables influence consumers' online shopping intention is the topic of this study.

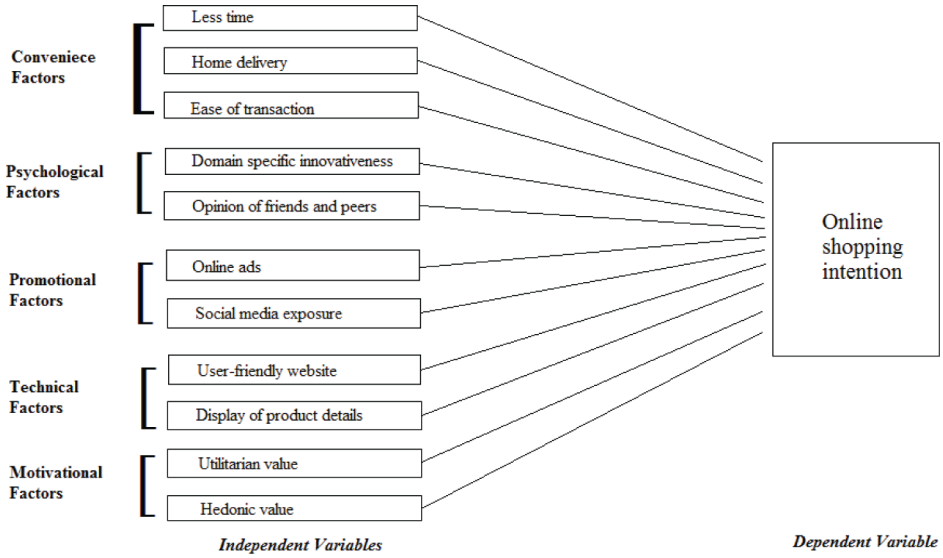
So, these factors containing the above-mentioned variables act as independent variables and consumers' online shopping intention act as dependent variable. On the basis of this frame, the conceptual framework was developed (Figure 1).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Using this model, the hypotheses can be developed as below:

H_0: Factors of online shopping do not significantly influence consumers' shopping intention.
H_1: Factors of online shopping significantly influence consumers' shopping intention.

Figure 1. Conceptual framework



SCOPE OF THE STUDY

This study discussed about the factors that influence consumers to shop online. It also identified the significant factors that instigated consumers to purchase online. This study is confined to only the samples taken from people residing in Dhaka, Bangladesh. The study focused on product retailing only. Online service delivery was not covered.

RESEARCH OBJECTIVE

The broad objective of this study is to measure the strength of the factors that influence the consumers to purchase online. This is divided into four specific objectives that this study tried to achieve. They are as follows:

- To identify the factors which are considered as the most significant ones in terms of influencing consumers to purchase online;
- To examine whether these particular factors apply in the context of Bangladeshi consumers;
- To obtain an understanding of the expectations of Bangladeshi consumers from the online retailers.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

METHODOLOGY

Nature of the Study

This is a descriptive study since it tries to find out the influence of factors on consumers to purchase online. Descriptive research is "a type of conclusive research that has as its major objective the description of something- usually market characteristics or functions" (Malhotra, 2015).

Type of Data

Both primary and secondary data were used to conduct this study. Secondary data were collected from other studies related to online shopping. Primary data were collected from respondents who purchased online using a survey. The target population of this study was the consumers who purchase online. The number of target population, for that reason, is uncountable.

Sample Size and Sampling Technique

Since this kind of test-marketing studies use 150-200 respondents, the sample size for this study was determined as 150. Non-Probability sampling technique was used to select the samples. The reasons for selecting non-probability sampling technique are 1) the variability in the population is low, 2) population size in undefined, 3) time and cost issues are available. Among the non-probability sampling techniques, convenience sampling was used.

Sample Element and Sample Unit

In this study, the sample element is a consumer who has the experiences of purchasing online. So, the sample unit here is an active Internet user who purchased online more than once.

Sampling Frame

The sampling frame is the Facebook friends of the researcher because these users have the greatest possibility of purchasing online. However, it was ensured that each respondent purchased online at least once.

Method of Data Collection

The data collection method was survey using questionnaire as the instrument. The questionnaire consisted of statements representing independent and dependent variables.

Type of Questions

The questionnaire is a structured questionnaire containing multiple choice questions. Since the study was supposed to find out the influence of factors of online shopping on customers, it required objective answers from the respondents for the analysis. Therefore, answers were numbered according to a measurement scale so that numerical findings come out.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Scale of Measurement

A 5-point Likert scale was used that ranged from 1 to 5 in which "1" denotes "strongly disagree", "2" denotes "disagree", "3" denotes "neutral", "4" denotes "agree" and "5" denoted "strongly agree". These categories were used to measure the level of agreement of the respondents with the statements.

Data Analysis Method and Statistical Tool

For analysis, Multiple Linear Regression Model was used to measure the influence of factors of online shopping. For performing regression model, SPSS version 16 software was used.

LIMITATION OF THE STUDY

While conducting the study, following limitations had to be faced:

1. **Time limitation:** Conducting a study on a population comprising of all the online shoppers of a country needs more time whereas the time limit of this study was only 3 months;
2. **Lack of experience:** In order to conduct such a large-scale project, previous experience helps a lot. However, the researcher lacks in that;
3. **Sampling limitation:** Since the population size was unknown, probability sampling techniques could not be employed. As a result, nonprobability sampling technique was used.

DISCUSSIONS, ANALYSIS AND FINDINGS

In this study quantitative analysis has been performed. The analysis method used for this study is Multiple Linear Regression Model. Here the strength of association between Facebook marketing and consumers' purchase intention has been measured. For data processing the IBM SPSS Statistical Software version 16.0 package has been used. Table 1 shows the model summary of the research.

Table 1. Model summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.556[a]	.310	.239	.920

Explanation

Here, by stating the model summary of the research, an attempt was made to identify the association between factors of online shopping and purchase intention created in consumers. R is called the correlation coefficient that represents the strength of association between dependent variable and independent

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

variables. Its value ranges between -1 and +1. When the value of R is positive, it suggests a positive association between dependent variable and independent variables (Malhotra and Dash, 2012-2013). From the above table, we can see that the value of R is .556 which indicates that there is a positive association between Facebook marketing and consumers' purchase intention in Bangladesh.

From the aforementioned figure, it can be observed that the value of R square is .310 which means that dependent variable is weekly associated with independent variables, i.e. 31.0% of variation in dependent variable is explained by independent variables. "The strength of association is measured by the coefficient of determination, R^2. It varies between 0 and 1 and signifies the proportion of the total variation in Y that is accounted for by the variation in X" (Malhotra, 2015).

Here, the value of adjusted R square is .239. As moderate difference between R square and adjusted R square can be noticed, there are opportunities to add more variables. "R^2 is adjusted for the number of independent variables and the sample size to account for diminishing returns. After the first few variables, the additional independent variables do not make much contribution" (Malhotra, 2015).

ANOVA Table

According to Malhotra (2015), "the F test is used to test the null hypothesis that the coefficient of multiple determination in the population R^2_{pop} is zero. This is equivalent to testing the null hypothesis." The significance level in the model was 0.00 which is less the 5% level of significance used in the model. It therefore follows that the model is statistically significant in predicting how the independent variables affect consumers' online purchase intention. On the other hand, F critical at 5% significance level is 3.17 while the F-calculated is 4.402. It therefore follows that the overall model is significant since the F-calculated is greater than the F-critical. Table 2 shows the ANOVA model.

Table 2. ANOVA

ANOVA						
Model		**Sum of Squares**	**df**	**Mean Square**	**F**	**Sig.**
1	Regression	40.974	11	3.725	4.402	.000[a]
	Residual	91.392	108	.846		
	Total	132.367	119			

Coefficient Analysis

Using the values shown in Table 3, the regression model becomes the following:

Consumers' purchase intention = .997 (Constant) - .030 (less time) + 0.482 (home delivery) - 0.204 (ease of transaction) - 0.358 (domain specific innovativeness) + 0.237 (opinions of friends and peers) + 0.068 (online ads) + 0.108 (social media exposure) – 0.038 (user-friendly website) + 0.148 (display of product details) + 0.334 (utilitarian value) + 0.054 (hedonic value) + e_i (error term)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Coefficient chart

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	Std. Error	Beta		
1	(Constant)	.997	.478		2.085	.039
	Less time	-.031	.131	-.030	-.237	.813
	Home delivery	.473	.115	.482	4.129	**.000**
	Ease of transaction	-.179	.127	-.204	-1.405	.163
	Domain specific innovative ness	-.335	.121	-.358	-2.764	.007
	Opinions of friends and peers	.206	.118	.237	1.747	.083
	Online ads	.059	.134	.068	.441	.660
	Social media exposure.	.100	.113	.108	.887	.377
	User-friendly website	-.029	.088	-.038	-.329	.743
	Display of product details.	.116	.102	.148	1.137	.258
	Utilitarian value.	.323	.100	.334	3.238	**.002**
	Hedonic value	.045	.084	.054	.544	.588

a. Dependent Variable: I would like to purchase things from online stores next time

The beta coefficients are the partial regression coefficients obtained. It "denotes the change in the predicted value, Y, per unit change in X when the other independent variables are held constant" (Malhotra, 2015).

Standardized coefficients calculated for each predictor variables, showing the percentage of variation in the dependent variable caused by the individual independent variables. It can be revealed that only the variable *'home delivery'* and *'utilitarian value'* are significant at *5%* level. The Standardized beta coefficient of home delivery is *0.482*(the highest) which means it is also the most important variable that influences purchase intention. The second most important variable is *'utilitarian value'* having a standardized coefficient of *0.334.* The third most important variable is *'opinions of friends and peers'*. Its standardized coefficient is *0.237.* The next important variable is *'display of product details'* having a standardized coefficient of *0.148.* Less time, ease of transaction, domain specific innovativeness and user-friendly website– these variables have negative standardized beta coefficients.

Correlation Matrix Analysis

From the correlation matrix (Appendix-2), we can see that maximum values are less than 0.5. We know that if the maximum values of correlation matrix exceed 0.5, then we must say that the research result is suffering from multi-collinearity problem. "Multicollinearity arises when the inter-correlations among the predictors are very high" (Malhotra, 2015). So, we can conclude that the research result is not suffering from the multi-collinearity problem.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

HYPOTHESES TESTING

H_0: Factors of online shopping do not significantly influence consumers' purchase intention H_1: Factors of online shopping significantly influence consumers' purchase intention.

From the coefficient table, the significance values for the two independent variables are 0.000 and 0.004. So, we can reject the null hypothesis (There is no significant impact of factors of online shopping on consumers' online purchase intention). So, it can be concluded that Factors of online shopping marketing has significant impact on consumers' online purchase intention.

RECOMMENDATIONS

1. Customers do not think that online shopping is time saving. So, marketers must try to reduce the overall time needed to process the order and deliver the product so that time is saved on their part;
2. Customers are highly influenced by the opinion of friends and peers. So, marketers must try to spread word-of-mouth to attract more customers to shop online;
3. Social media exposure proved to be a vital medium to serve for online shopping for the customers. So, marketers might also use this medium as wisely as possible to generate a huge amount of visit by the customers.

CONCLUSION

Online shopping is getting more popular day by day. And it will not be surprising if it replaces the popularity of offline shopping. In this study several problems of online shopping have been identified. If marketers can properly eliminate these problems and utilize the field, it can generate huge revenue for them. Already we can see the omnipresence of the social media. It can also be a good medium for online shopping as well. If the overall perception of online shopping can be slightly changed, people can willingly prefer online shopping to offline provided that the ever-increasing traffic jam of Bangladesh is day by day making the movement of cars slow to impossible. Besides, huge number of people always go for shopping that creates an awkward gathering of people in shopping malls. In order to avoid all these inconveniences online shopping can be a sigh of relief for the consumers in Bangladesh. So, it can be a great opportunity for the online marketers to turn these consumers to online shopping.

ACKNOWLEDGMENT

The author would like to thank Md. Omar Al-Zadid for his assistance and guidance in data collection and developing the initial version of this work. The author also thanks Joan Schnitzer for doing an excellent edition job.

APPENDIX A: QUESTIONNAIRE

Questionnaire

Welcome to this survey. Please give your answers by choosing from multiple choices under the following statements. Your answers will be used only for research purpose.

1. Online shopping requires less time than shopping from physical stores

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

2. The option of home delivery is the most convenient thing about online shopping

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

3. I find the transaction process in online shopping more secure

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

4. I feel interest in purchasing new products in new ways

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

5. The opinion of friends and peers are useful for me to take decisions

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

6. Online ads make me interested in an online store by giving me useful information about the product and the brand

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

7. Social media, in my opinion, is a perfect place for an online store to get exposure

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

8. A user-friendly, easily navigable and searchable website is necessary for me to think of online shopping

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

9. If the features of a product cannot be examined in detail, it is risky to shop online

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

10. Shopping online can be considered as a needed part of our life

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

11. As a consumer, I think online shopping has the ability to give me pleasure and excitement and make me look 'cool'

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

12. I would like to purchase things from online stores next time

Strongly Disagree	Disagree	Neither Agree Nor Disagree	Agree	Strongly Agree
1	2	3	4	6

Chapter 27
Best Customer Experience in E-Retailing:
A Knowledge-Based Empirical Model

Tahir Iqbal
https://orcid.org/0000-0002-5234-3676
Imam Abdulrahman Bin Faisal University, Saudi Arabia

ABSTRACT

The main purpose of the research is to empirically test a model for assessing the association between outcomes as well as antecedents of online customer experience (OCE) in e-commerce websites in the case of KSA. The theoretical implications of customer online shopping behaviour have largely been discussed in the previously conducted studies however less consideration has been provided to the antecedents of e-retailing shopping and its effect on customer online shopping experience pertaining to KSA. The study has incorporated a quantitative method under which the data has been collected through primary sources using the survey. The sample of 150 respondents has been incorporated who provided their responses through a survey questionnaire. The questionnaire consisted of 13 questions and included five-point Likert scale in order to incorporate responses. The technique of analysis incorporated demographic analysis, correlation analysis and SEM model using SPSS and SmartPLS. It was identified that providing efficient online shopping experience through Tele-presence, ease of use and perceived benefit has a significant positive impact on consumer shopping experience pertaining to the shoppers of KSA.

1. INTRODUCTION

With the advancement in the technology, the competition in businesses is also increasing and in this essence, the emergence of e-retailing is prominent (Rose et al., 2012; Srikanth and Dhanapal, 2011). E-retailing can be deemed as a phenomenon which incorporates sales through online or electronic channels of the products and services (Dixit, 2016; Sarkar and Das, 2016). Therefore, with technological integration, the businesses are found to be keen to incorporate effective management strategies that can result in better customer experience (CE) (Hicks, 2018). The concept pertaining to customer experience deriving

from online channels is now regarded as online customer experience (OCE) as stated by the research of (Salehi et al., 2013; Bleier et al., 2019). It has been due to the fact that better customer experience with the brand can lead to higher performance. Rose et al. (2011) in this essence stated that OCE is one of the significant factors that is affecting the aggregate performance of the organisations. Hence, this research is aimed to test a model empirically for assessing the association between outcomes and antecedents of OCE in e-retailing shopping website and the impact of those antecedents on CE in the case of Kingdom of Saudi Arabia (KSA). There are limited researches that have underpinned KSA's case, for instance; the research of Palací et al. (2019) considered the subject of customer satisfaction's (CS) antecedents and fragmented them into effective and cognitive tradition. Besides, the research of Rose et al. (2012) analysed OCE's antecedents' effect on OCE while considering the dimension of repurchase intention in the case of Malaysia. However, the researches in the same context on KSA are limited, therefore, the following research has addressed this gap due to increase in KSA's online shopping appetite of shoppers. According to a survey conducted by Mastercard (2014), there was a rise in online shopping in KSA and as per statistics at least every person e-shopped in a year. Therefore, this study has been focused on finding the antecedents of e-retail market and creating an empirical model to show the relationship of these antecedents with OCE as well as the impact of the former on the latter considering KSA which will be beneficial for the upcoming e-retailers to devise their strategies and the existing one to mend them. The main objectives of the research paper are stated as follows:

- To study the concept and idea of online customer engagement;
- To identify the components of online customer engagement;
- To assess the relationship between the factors of OCE associated with e-retailing based on antecedents and outcomes variables in the case of KSA.

2. LITERATURE REVIEW

2.1. Online Customer Experience

According to the study conducted by Novak, Hoffman and Yung (2000), the concept of customer experience is the subjective and internal response of the customers that are received by the indirect or direct connection with the company. Customer experience has also been regarded as the psychological construct in the literature that is also associated with customer involvement with the company or a brand. On the other hand, the study of Rose et al. (2012) professed that online customers often experience the receiving of sensory data on the website of the brand in the form of video, visual imagery and content-based information. It has also been posited in the research of Lim and Ayyagari (2018) that customer interprets and makes assumptions about the data for available on the websites and creates perceptions about the products and service of the brands. The study further explained that these perceptions and interpretations create overall OCE in either a positive or negative manner. The study of Yarimoglu (2014) has regarded OCE as the notion of total time spent by the customer on a single website that further affects their repurchasing behaviour. Therefore, the theoretical underpinnings of OCE have been associated with a customer experience which has been largely discussed in the literature.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

2.2. Antecedents and Outcomes of E-Retailing

The antecedents of e-retailing shopping experience have been taken from various studies such as Novak, Hoffman, and Yung (2000), Koufaris, Kambil and LaBarbera (2001) and Al-Debei, Akroush and Ashouri (2015). First, the study conducted by Novak, Hoffman, and Yung (2000) has been analysed in order to obtain theoretical support underpinnings of this research and to formulate the hypothesis. The research has undertaken the model called flow and included the variables in this model. It has been identified that flow is the effective way of enhancing OCE through the flow of information and it is also regarded as the state in which the customer is entirely engrossed in the activity. Therefore, the model proposed by Novak, Hoffman, and Yung (2000) has consisted of the variables such level of challenge, interactivity speed, Tele-presence and skills. This research has included the speed of interactivity and Tele-presence as the two variables amongst the five identified variables. The research of Lim and Ayyagari (2018) stated that Tele-presence in OCE is the use of virtual reality on the websites that will clearly show the customers all the basic attributes of the product. On the other hand, Changal (2005) stated that the speed of interactivity can impact OCE. Therefore, the hypothesis (H1) has been formulated in Table 1.

The remaining variables have been taken from the study of Koufaris, Kambil and LaBarbera (2001) in which the researchers have included the five variables namely ease of use, customisation, connectedness, perceived and aesthetic benefits. Amongst all these variables, the present research has undertaken ease of use, connectedness and perceived benefits in order to identify their impact on OCE. The various studies such as Prashar, Sai Vijay and Parsad (2017), Nagra and Gopal (2013) and Lin (2006) have supported the inclusion of connectivity in the context of customer experience where the study of Prashar, Sai Vijay and Parsad (2017) has explained the connectivity can be regarded as the way through which the companies create values on their website and hence affect the customer online behaviour. On the other hand, studies such as Akhlaq and Ahmed (2014), Shanthi and Desti (2015), Rizwan et al. (2014) and Ibrahim et al. (2013) have emphasised the ease of use as the major variable that can impact the effectiveness of online shopping behaviour. Lastly, the studies such as Al-Debei, Akroush and Ashouri (2015), Doolin et al. (2005) and Santana and Loureiro (2010) have emphasised perceived benefits as the major variable that can impact the efficiency of online shopping behaviour. Doolin et al. (2005) have further identified that the perceived benefits such as price comparison, convenience, saving time and enjoyment can impact OCE and can significantly impact the relationship between the retailer and the customer. Therefore, Table 1 shows the hypotheses (H1 to H5) created for testing how each variable has impacted OCE in e-retail market.

The research underpins the assessment of the effect of OCE's antecedents on the OCE while considering the case of KSA. The research of Rose et al., (2012) explained some of the e-retailing antecedents which have been considered in this study including connectedness, telepresence, speed of interactivity, ease of use and perceived benefits. However, the antecedents were not tested in the case of KSA. The statements presented under building hypotheses are representing the empirical analysis of the study which can be deemed as the proposed statements. Therefore, the hypotheses have been formulated to examine the case of KSA's OCE and e-retailing antecedents which are effective in improving OCE for profitable organisational performance.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

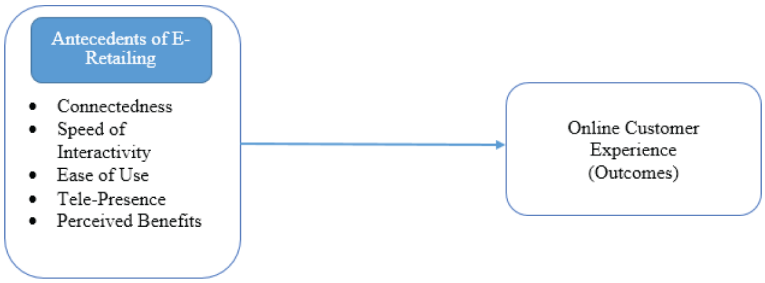
Table 1. Hypotheses formulation

Building Hypothesis	Key Supporting Literature	Hypothesis Formulation
The higher the experience of the Tele-presence by the customers at Internet shopping websites, the higher is the OCE	Novak, Hoffman and Yung (2000), Lim and Ayyagari (2018) and Liu and Teo (2004)	**H1**: Tele-presence has a significant positive impact on OCE in the case of KSA
The higher the experience of the Speed of interactivity by the customers at Internet shopping websites, the higher is the OCE	Novak, Hoffman and Yung (2000), Changal (2005) and Islam (2009)	**H2**: Speed of interactivity has a significant positive impact on OCE in the case of KSA
The higher the Ease of use by the customers at Internet shopping websites, the higher is the OCE	Koufaris, Kambil and LaBarbera (2001), Akhlaq and Ahmed (2014), Shanthi and Desti (2015), Rizwan et al. (2014) and Ibrahim et al. (2013)	**H3**: Ease of use has a significant positive impact on OCE in the case of KSA
The higher the Level of connectedness by the customers at Internet shopping websites, the higher is the OCE	Koufaris, Kambil and LaBarbera (2001), Lin (2006), Prashar, Sai Vijay and Parsad (2017) and Nagra and Gopal (2013)	**H4**: Level of connectedness has a significant positive impact on OCE in the case of KSA
The higher Perceived benefits by the customers at Internet shopping websites, the higher is the OCE	Al-Debei, Akroush and Ashouri (2015), Doolin et al. (2005) and Santana and Loureiro (2010)	**H5**: Perceived benefits have a significant positive impact on OCE in the case of KSA

2.3. Conceptual Framework

Pertaining to the variables discussed in the literature and hypotheses, the model has been formulated in Figure 1.

Figure 1. Conceptual framework



The figure displayed above is the conceptual framework of the study comprised of variables both independent and dependent. The independent variable named antecedents of e-retailing. As per the framework, the variable "antecedents of e-retailing" is divided into the speed of interactivity, Tele-presence, ease of use, connectedness and perceived benefits. On the other hand, the dependent variable of the study, as shown in the conceptual framework is OCE outcomes which can be either in terms of trust, satisfaction or repurchase intention of the consumers.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

3. METHODOLOGY

This research is based on a quantitative research design where a close-ended questionnaire was designed for data collection. The questionnaire has been based on the variables adopted from different studies whereas the scale was being set on five points Likert scale including strongly agree, agree, neutral, disagree and strongly disagree. The researcher accumulated primary data from where the respondents were online shoppers residing in KSA. According to Asharq Al-Awsat (2017), there are approximately 26 billion internet users in KSA while 88% of them use e-commerce. This forms approximately 22.88 billion yet this population was inaccessible for the researcher. Therefore, the researcher used convenience sampling so the participants were chosen from the proximities of the researcher's place. The distribution of the sample took a week where online channels were used while some questionnaires were distributed physically as well. Initially, it was distributed to 250 participants, however, 38 of them refused to take part, 29 did not return the questionnaire and 33 were incomplete, therefore, those responses had to be omitted for final analysis. The time to collect and organise the data took 3 months which initiated in mid of March 2018. Thus, the sample size of the research study has been sanctioned to 150 customers which has been estimated through Statistical Package for the Social Sciences (SPSS) software for basic statistics and SmartPLS have been used for SEM model along with correlation analysis. Therefore, the techniques incorporate SEM, correlation and demographic analysis.

4. RESULTS

The results have been presented in three sections where the first one deals with demographic analysis, the second section is related to correlation analysis and the third one is related to the structural model.

4.1. Demographics

The sample consists of 55.33% males while 44.67% are females. In addition, the people belonging to 25 to 30 years form 30%, 21 to 35 years form 34.67%, 36 to 40 years form 22.67% and 41 years and above forms 12.67%. The graphical presentation of the data can be seen in Figures 2 and 3.

Figure 2. Gender of the respondents

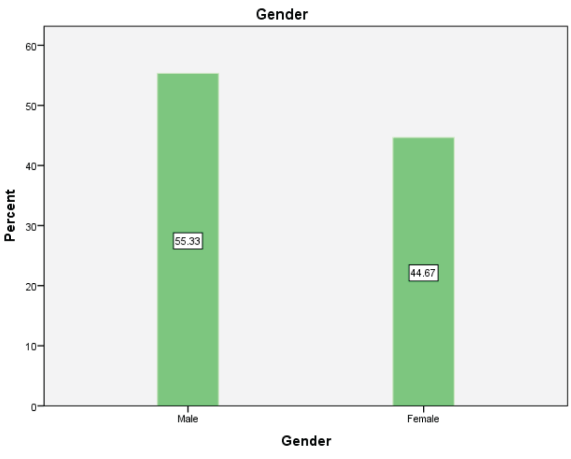


Figure 3. Age of the respondents

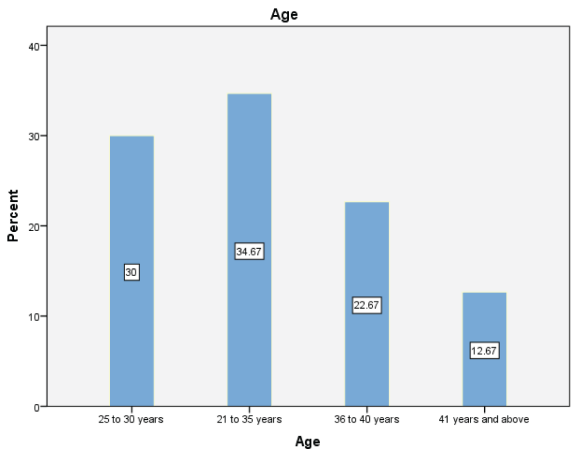

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.2. Correlation Analysis

In order to analyse the association of e-retailing antecedents with the OCE, the correlation has been conducted. Correlation analysis has been defined as the scientific and statistical method that is used in order to find the relationship between the study's variables (Silverman, 2018). The main variable of the study is OCE which has been explored therefore, the association of connectedness with OCE is found to have a value of 0.564. The association is positive and moderate asserting that both variables would navigate in the same direction. The link of OCE with ease of use is found to be 0.689 which is strongly moderate and positive so, both will move in the same direction with a stronger magnitude. The case with perceived benefits and OCE is also similar to previously mentioned relationship because it has a value of 0.645, however, the association is found to be strongly moderate and positive. The antecedent of the speed of interactivity is positive but quite weak as the value if 0.135. Moreover, the variable of telepresence has a positively moderate association with OCE. Hence, all correlations are positive in the case of KSA. Table 2 shows the correlation analysis.

Table 2. Correlation analysis

	Connectedness	Ease of Use	OCE	Perceived Benefits	Speed of Interactivity	Tele-Presence
Connectedness	1.000					
Ease of Use	0.797	1.000				
OCE	0.564	0.689	1.000			
Perceived Benefits	0.813	0.789	0.645	1.000		
Speed of Interactivity	0.165	0.153	0.135	0.081	1.000	
Tele-Presence	0.639	0.778	0.673	0.624	0.264	1.000

4.3. Structural Model

Firstly, the reliability of the instrument based on the variables of the study has been tested. The acceptable value of the constructs' reliability is 0.6 which is stated by Ursachi et al., (2015) and Hair et al (2016). Hence, all variables have reliability above the threshold of 0.6. In addition, the composite reliability is also computed to be significant as the values are extremely high. The convergent validity is recognised using Average Variance Extracted (AVE) which according to threshold should be above 0.5 (Huang et al., 2013). Besides, the threshold for factor loadings according to Kline (2015) is 0.5. Hence, all factor loadings are significant of all variables of the study. The results can be viewed in Table 3.

Another significant concept while analysing a structural model is discriminant validity which opines that the variables should be unrelated to each other to produce better outcome and results with reduced errors (Wang, 2015). In this case, the research of Henseler et al. (2015) asserted that HTMT ratio should be below 0.9 to surpass the acceptability criterion. All the values mentioned below in the table are lower than 0.9 therefore, the discriminant validity is also proven of the variables, as shown in Table 4.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 3. Reliability, validity and factor loadings

Variables	Indicators	Factor Loadings	AVE	Cronbach Alpha	Composite Reliability
Connectedness	C1	0.940	0.894	0.941	0.962
	C2	0.951			
	C3	0.946			
Ease of Use	EU1	0.911	0.762	0.694	0.865
	EU2	0.834			
OCE	OCE1	0.695	0.690	0.925	0.939
	OCE2	0.785			
	OCE3	0.828			
	OCE4	0.882			
	OCE5	0.914			
	OCE6	0.888			
	OCE7	0.804			
Perceived Benefits	PB1	0.947	0.909	0.900	0.952
	PB2	0.960			
Speed of Interactivity	SI1	0.820	0.743	0.661	0.852
	SI2	0.903			
Tele-Presence	TP1	0.761	0.629	0.804	0.871
	TP2	0.845			
	TP3	0.781			
	TP4	0.783			

Given this, the model description based on path analysis has been presented as follows. The table illustrates that the significant variables include ease of use, perceived benefits and telepresence concerning KSA's OCE. The effect of all the variables can be seen as positive referring to then significant ones. This surmises that improvement is any of the significant antecedents whether ease of use, perceived benefits or telepresence would lead to betterment in the OCE of the KSA shoppers. The significance has been deduced as per the p-value whose threshold is 0.05 as per the study of Cheng (2017), and Spokoiny and Dickhaus (2015) specifically when the confidence level is undertaken to be 95%. Therefore, speed of interactivity and connectedness have been found to be insignificant in these scenarios. Table 5 dispays the table of path coefficients.

For the purpose of assessment of the model's quality, the value of adjusted R-squared and R-squared have been presented as follows. The research of Gordon (2012) and Schumacker and Tomek (2013) demarcated the concept of both by stating that the variation in the predictors explaining the variation in the predictand can be deemed as R-squared whereas, adjusted R-squared is its modification which exhibits more accurate value because it adjusts the values with every increase in the predictors. Hence, the variation in e-retailing antecedents is explaining 55.3% variation in OCE related to KSA which is further declined to 53.7% subsequent to the adjustment. The Table 6 presents the results.

Table 5. Table of path coefficients

	Path Coefficients	T Statistics	P Values
Connectedness -> OCE	-0.142	0.848	0.397
Ease of Use -> OCE	0.274*	2.009	0.045
Perceived Benefits -> OCE	0.328*	2.314	0.021
Speed of Interactivity -> OCE	-0.001	0.029	0.977
Tele-Presence -> OCE	0.346*	3.384	0.001

Table 6. R-squared and adjusted R-squared

	R Square	R Square Adjusted
OCE	55.30%	53.70%

Table 7. Hypothesis formulation

Hypothesis Formulation	Decision
H1: Tele-presence has a significant positive impact on OCE in the case of KSA	Supported
H2: Speed of interactivity has a significant positive impact on OCE in the case of KSA	Unsupported
H3: Ease of use has a significant positive impact on OCE in the case of KSA	Supported
H4: Level of connectedness has a significant positive impact on OCE in the case of KSA	Unsupported
H5: Perceived benefits have a significant positive impact on OCE in the case of KSA	Supported

Thoroughly analysing the data, the summarised table whether the hypotheses are accepted or negated are presented below. The first statement of hypothesis underpinned telepresence's significant impact on OCE which is supported because the p-value was 0.001 (p-value < 0.05). The next hypothesis pertaining to speed of interactivity is unsupported because the p-value is 0.97. The third hypothesis is regarding ease of use which is supported as the p-value is 0.045 and the fourth hypothesis is rejected with p-value 0.397. The last hypothesis regarding perceived benefits is supported with a p-value of 0.021. Therefore,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

pertaining to KSA, ease of use, telepresence and perceived benefits have been found to be significant and positively affecting the OCE. Table 7 shows the hypothesis formulation.

5. DISCUSSION

The main purpose of conducting this research was to develop and test a model empirically for assessing the relationship between outcomes and antecedents of OCE within e-retail shopping websites by drawing upon the extensive research. For this purpose, the conceptual model has been developed along with the empirical analysis of data collected from the customers of different communities who prefer to purchase through online websites. The study has offered new insights into the results and provided theoretical and practical implications for both practitioners and academics. The results of the study have coincided with the results of the researches conducted by Novak, Hoffman and Yung (2000), Changal (2005) and Islam (2009), Lim and Ayyagari (2018) and Liu and Teo (2004), Koufaris, Kambil and LaBarbera (2001), Lin (2006), Prashar, Sai Vijay and Parsad (2017) and Nagra and Gopal (2013). The study has also made the various contributions amongst which the most important has been the addition of new knowledge horizons into OCE in the case of KSA. For instance, the study has made the combination of those variables that were not being studied in any previous study; Koufaris, Kambil and LaBarbera (2000), Novak, Hoffman and Yung (2000) and Changal (2005); especially with respect to OCE.

6. CONCLUSION

The main purpose of conducting this study is to develop and test a model empirically for assessing the relationship between outcomes and antecedents of OCE within internet shopping websites. The results have achieved through correlation, regression and factor analysis and identified that speed of interactivity; Tele-presence, ease of use; connectedness and perceived benefits are the main antecedents of the e-retail market and have a significant impact on OCE. These antecedents have been derived from various studies in order to create a conceptual model and to apply the empirical tests in order to obtain results. The theoretical contribution of this research is associated with the proposed model indicating the factors such as Tele-presence, ease of use and perceived benefits having an impact on OCE pertaining to KSA shoppers. This is a major contribution of this research to the existing body of knowledge that does not show theory combining all these factors as the antecedents of online shopping impacting customer online shopping experience. In theory, all the identified antecedents have been regarded as important in the e-retailing sector; but, OCE has not been set as the measuring scale for identifying the success of the antecedents of online shopping in the case of KSA. Appendix A includes the Survey Questionnaire, and Appendix B shows the Path Models.

This research also has a number of managerial implications such as the various e-retailers would be allowed to distinguish amongst the factors that can make a difference between online and offline customer experience. Using these factors, the organisations will be able to offer a convenient and exciting shopping experience to customers allowing them to continuously and consistently purchase from their brand. Organisations using online retailing would be able to analyse and understand the perceptions of the customers regarding the benefits of e-retailing. With regard to this, different perceived benefits can be turned into actual benefits offered to the customers inclining them to make more purchases from the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

online shopping website. However, there have also been a number of limitations such as the study has not included the respondents from the age group of generation Y (18-24 years) whereas the sample size of the study has also been limited to 150 respondents. For future researchers, it has been recommended to incorporate different age groups, larger sample size and some qualitative aspects of the research as well.

Chapter 28
The Online Reviews' Effects on Internet Consumer Behavior:
An Exploratory Study

Mingli Zhang
Yanshan University, School of Economics and Management, Qinhuangdao, China

Suyun Ding

Yuanwei Bian
Yanshan University, School of Economics and Management, Qinhuangdao, China

ABSTRACT

Consumer behaviors have always been the hot spot of the study. With the arrival of the network age and the popularity of e-commerce, the consumption pattern of shopping online is beginning. Until December of 2014, there were 649 million Internet users in China, and it's increasing. In the year of 2014, the number of most mainstream online shoppers has increased by 23.7% and shopping online has become an irresistible trend. New consumption mode can produce a new research subject, the study of Internet consumer behaviors becomes very important. This article used LocoySpider, a data mining software, to mine Taobao online reviews. Through the analysis of online reviews, we can study the effect of online reviews on consumer behaviors. During the study, we set the risk perception as intermediary variable. By the study, we can help the electronic commercial enterprises to attract customers, retain customers and reduce the information search cost.

INTRODUCTION

With the development of the Internet, we have entered the e-commerce age. Great changes have taken place in people's lives: sites like Alibaba, Amazon, Jingdong have changed people's consumption patterns. According to CNNIC, the number of Internet users has reached 649 million by December 2014 in

China. Compared with the previous year, the growth rate is 5%. The number of active buyers on Alibaba platform has reached 255 million. Only in the third quarter of 2015, Taobao's GMV has arrived 438,000 million yuan, it's growth rate is 15% year-on-year. From the data above, we can see that shopping online has become a hot trend. When the consumers go shopping online, they would browse online reviews to find the merchandise news which can help them know more information about the goods. The historical and cultural environment of our country has great influences on the consumers, so consumers' purchase decisions are easily affected by others. According to the survey by Deloitte's Consumer Products, we can see that there will be 67% of Internet users to browse online reviews, 82% of them think that online reviews can affect their purchase decisions directly. So, online reviews have important influences on consumers' purchase decisions. So, it has great importance to study online reviews.

Through the study of online reviews, we can know the characteristics of online reviews, so that we can grasp the focus of consumers. Based on the understanding the mechanism of reviews' influences on consumer behaviors, the online merchants can find out their disadvantages. So, they can improve the quality of products and services and control the influences of online reviews dissemination effectively. Some specialists have made some studies about online reviews, for examples Gu and Xu (2015) built the index system of online reviews from two dimensions which are the quality of content and the value of the reviewers. The online reviews can be divided into four categories. They are efficient reviews, suspicious comments, potential comments and invalid comments. Through the analysis of their usefulness, we can distinguish the efficient comments and use them. Mudambi and Schuff (2010) published a paper in MISO, it has defined the concept of online reviews' usefulness. They used the theories of information economics and the framework of decision-making uncertainty. Based on the data of Amazon, their analysis showed that the extreme comments and the length of the comments has directly influences on online comments' usefulness. At the same time, they researched the regulatory effects about search products and experience products. Yan, Zhang, and Zhang (2015) studied whether the content of online reviews has impacts on the usefulness of comments. They found that the deeper and more objective the online comments are, the higher the usefulness of comments is. The higher the product matches the description degrees and the more information of product characteristics the reviews have, the higher are the usefulness of comments. Chen and Xu (2014) studied the online comments from two perspectives, they are the characteristics of review and the information of reviewers.

They analyzed the factors that could affect the online review to acquire online comments' useful votes. From the study, they found that the comment score has a negative effect on online reviews' useful votes and the richness of comment information. The historical evaluation has a positive influence on its usefulness. Hao, Ye, and Li (2010) had set up the model of influential factors of online comments usefulness. They found that positive emotional tendency, the higher mixed degree of the positive and negative emotion, the higher mixed degree of subjective and objective expression and the longer the average sentence have significant positive effect on the usefulness of comments. Ning and Sun (2014) studied the influences of negative online comments on online consumers' purchase intention from the aspects of the number of negative comments, the degree of its negative, the contents, etc. On this basis, Zhou, Li, and Mou (2015) took the psychological distance as intermediary variables to study online reviews' influences on online consumers' purchase intention. They also studied the mediation comments' influences on online purchase intention which is under the regulation of different commodity types. Mo and Li (2015) studied the number of mixed reviews, favorable reviews and unfavorable reviews. Thus, it is concluded that the number of them has effects on consumer purchase intention. These studies made great contributions to the study of online reviews later.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Even though some specialists have made great achievements in the study of online comments, some of their studies only focus on the usefulness and authenticity by mathematical models. Other specialists studied the influences of online reviews on consumer behaviors from the perspective of psychology without intermediary variables. This article will take the risk perception as the intermediary variable to study the effects of online reviews on consumers' purchase intentions (David P. MacKinnon, 2008; Chang, Cheung & Tang, 2013). It is different from traditional data-collection method, we will use the date acquisition software, LocoySpider, to collect online reviews. Then carry out the empirical analysis (Chen, Xu, & Fan, 2012). With the utilization of big data technology, the research can be more objective and real.

LITERATURE REVIEW

Online comment is also called network comment or Internet word of mouth, which refers to personal experience, the evaluation of the product, the discussions and products promotion information spreading on the Internet concerned about products, services and enterprise brands. As the summaries of purchase experiences, both online reviews and the traditional reviews have many similarities. For example, they made conclusions about the characteristics of products' quality, price, price ratio, and so on. But as a product of new era, online comments are different in some degree. Compared with the traditional comments, online reviews are fast, informative, storable, anonymous, measurable. Many scholars have investigated the online reviews from different aspects.

The Risk Perception

Risk perception is a concept of psychology, many scholars have taken risk perception as variables to study consumer behaviors. In this paper, we take risk perception as intervening variable to study the online reviews' influences on Chinese consumers' purchase intentions. Some scholars usually believe that there are two kinds of risks, one is the subjective risk and the other is the objective risk. Among the amount of the studies, Chen (2013) studied online trade willingness from aspects of risk perception and website trust. Dong (2005) put forward the four dimensions of risk perception: the risk of online retail service, the attendant risk, the risk of personal privacy and the fake goods risk, etc. Based on the classification standard of Dahai Dong, we set up three indexes to measure risk perception. They are the risk of service, the risk of quality and the risk of logistics.

The Characteristics of Online Reviews and Reviewers

The characteristics of online reviews and reviewers are the important indicators to take the study, setting up the measurements of online reviews and reviewers is the basis of online reviews' research. Many scholars have established many indicators in the process of research, as it is shown in Table 1:

Based on online reviews' indicators in Table 1 and taking all the factors into consideration, we set up three indexes of online reviews' characteristics which are the length of the reviews, the strength of the reviews' tone and the richness of the description. We use the credit score to measure the characteristics of the reviewers. And we use the degree of satisfaction, purchase intention and likable degree to measure consumers' purchase intention.

HYPOTHESES AND RESEARCH MODEL

The Influences of Risk Perception on Purchase Intention

The risk perception is the psychological assessment on the risk of shopping online, when network consumers face the uncertainty Internet environment. The risk perception contains the risk of quality, the risk of service and the risk of logistics.

The risk of quality refers to the network consumers' psychological assessment that if the products' actual quality is consistent with the description of the goods. Shopping online has the characteristics of fast, convenient and meeting the demand without leaving home. Shopping online has brought many conveniences to people's lives, but the characteristics of it lead to the separation of time and space in the process of it. When we choose the product, without touching and getting the perception of its quality closely, we can only evaluate the quality of product through the descriptions. So, it may exist the conditions that products' quality are not in conformity with description of actual situation. And consumers will determine whether the quality of the goods and the description are consistent or not according to

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the description of online reviews. The consumers' risk perception about the quality of the goods will affect the online consumers' purchase intention.

The risk of logistics refers to network consumers' psychological assessment of the possible risk in the process of logistics. Because shopping online has the characteristic of spatial separation, consumers could not immediately get the product after buying them. It needs to go through the logistics process before consumers get the goods. During the process of delivery some problems may come up. Although the economic loss of logistics is not bearing by consumers, the consumers still perceive the risk. For example, the loss of the goods and the speed of logistics can affect the consumers' mood, it may delay the time of using the goods and take consumers more time costs. So, the risk of logistics will affect consumers' purchase intentions.

The risk of service refers to the network consumers' psychological assessment of the risk in the process of service. Due to the spatial isolation of shopping online, consumers cannot take actual experience on the products, consumers can consult a lot of questions about the products in the process of the shopping online. The attitude of merchants and the timeliness of answering the questions will affect consumers' purchase intention. The convenience of shopping online determines that consumers can turn to other merchants easily with a low cost of clicking the mouse. For example, if it has long response time or their attitudes are bad, the consumers may feel that they are not respected. Then the purchase intentions of the customers will reduce. If the sellers can answer the questions in time and their services are very enthusiastic, they will acquire more trust from the consumers, which will increase consumers' willingness to buy goods and help consumers make their purchase decision.

The risk of quality, the risk of service and the risk of logistics can present the risk perception. So, the risk perception can affect the consumers' purchase intention. If the risk perception of the consumers is smaller, their purchase intention will be stronger. On the contrary, if the risk perception of the consumers is bigger, they will give up buying the goods. Thus, we propose the following Hypothesis:

H1: The risk perception has negative influences on consumers' purchase intention.

The Influences of Online Reviews on Risk Perception and Purchase Intention

Online reviews have a significant impact on Internet consumer behavior, which are suggestions offered by a third party besides the sellers and buyers. Compared with the suggestions offered by the sellers, the product introductions provided by consumers will be more objective. Because the reviewers and the browsers are in the same position, reviewers' opinions were more likely to be accepted by the browsers. We will reveal the online reviews' influences on Internet consumption behavior below.

In the process of shopping online, the online reviews have great influences on consumers' risk perception and purchase intention. In this paper, we will study the online reviews from the following aspects.

Online reviews are the feelings of consumers after buying and using the commodities. Then the consumers write them in the text form and provide references for helping the following consumers. The characteristics of online reviews refer to some essential properties of online reviews, such as the number of the total words, the number of emotional words and their emotional color, the description dimension of the commodities, and so on. We can use the strength of the reviews' tone, the length of the reviews, the richness of the description to measure the characteristics of online reviews.

The length of the reviews refers to the number of online reviews' word. If the consumers have more feelings about the quality of the goods and characteristics of the products, they will tend to use more

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

words to describe the products. If their experiences are not deep, the consumers often comment it with less words and even do not post reviews. Some retailers have realized online reviews' influences on consumers. In order to get favorable reviews, the sellers will adopt the method of cash back to encourage consumers to give high praises. Some consumers will give favorable reviews in order to get cash back rewards in the condition that the goods don't deserve. On this occasion, the reviews could be more perfunctory and have a little of words. Mentally, consumers think that the more words the online reviews have, the more credible the comments are. The deeper the review is, the smaller the risk perception of consumers is. Then they will increase the consumers' purchase intention further.

The strength of the reviews' tone refers to the number of emotional words and their emotional color. When consumers comment on products, they often use a variety of modal particles, such as dislike, like, like it very much, and so on. These words give consumers different feelings in psychological. If the tone of online reviews is stronger, the reviews will get other people's identity easily, and it will have strong persuasiveness. We can judge whether the online reviews are authentic according to the strength of the reviews' tone. And its authenticity can reduce the risk of consumers' awareness and increase consumers' purchase intention.

The richness of the description is the dimensions of online reviews that describe the goods or services. Some consumers focus on the fabrics; some of them think logistics is very important; some of them think service is important to customers. Only a few people make the reviews in a comprehensive way. The tremendous amount of online comments can affect consumers' awareness of the commodities. The larger the comments' richness is, the easier they can reduce consumers' risk perception and enhance their purchase intention.

From the measurement indexes above, we can see that the characteristics of online reviews have great influences on consumers' risk perception and consumers' purchase intention. If the characteristics of online reviews is very good, it will reduce consumers' risk perception and increase consumers' purchase intention. On the contrary, it will increase consumers' risk perception and reduce consumers' purchase intention. Thus, we propose the following hypotheses:

H2: The characteristics of online reviews have negative influences on consumers' risk perception.
H3: The characteristics of online reviews have positive influences on consumers' purchase intention.

The depth of online reviews, the strength of the reviews' tone and the characteristics of the reviewers will affect consumers' psychological distance. The deeper and stronger reviews and the reviewers with higher credit scores can make consumers' psychological distance closer. This phenomenon will reduce the risk perception of consumers and increase trust perception. Plus, the number of comments and month sales volume will increase the influences on consumers' purchase intention. It will prompt consumers to make purchase decisions. The process of online reviews' influences on network consumers is continuous, so we should plan it as a whole system when we study it. Then we can get the following Hypothesis:

H4: The characteristics of online reviews can affect consumers' purchase intention through the risk perception.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Online Reviewers' Influences on Internet Consumption Behavior

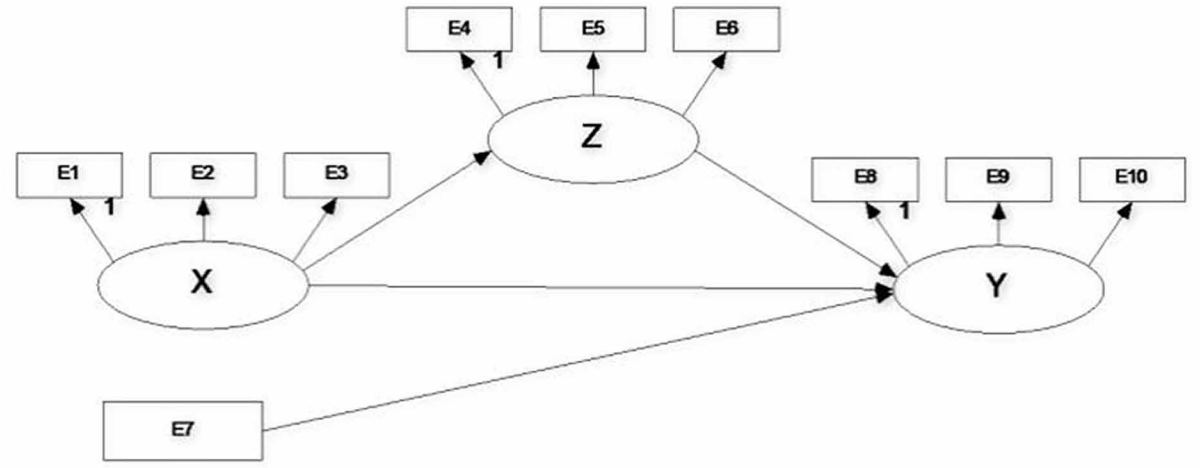
The depth of online reviews, the strength of the reviews' tone and the richness of the description are studied based on the characteristics of the online comments. Addition to these characteristics of reviews, the reviewers who have many experiences and credibility of shopping online could also affect consumers' risk perception and purchase intention. In this paper, we use the credit score to represent the consumers' experiences and credibility of shopping online. Credit score refers to the evaluation of the network consumers after they go shopping online. Every time they go shopping online, they will have one chance to acquire evaluation. The reviewers with high credit scores tend to have rich experiences in making online reviews. They know more information about how to discuss the products. Due to their high credibility and rich experiences, the reviewers with high credit scores may have a position of authority. Therefore, they tend to get consumers' trust and recognition more easily. So, they can affect consumers' purchase intention. Otherwise, the reviewers with low credit scores tend not to be trusted. Then we can get the following Hypothesis:

H5: The credit score has positive influence on consumers' purchase intention.

The Model

From the Hypotheses above, we can get the theory model about the impacts of online reviews on consumer behavior. The model is shown as Figure 1:

Figure 1. The model diagram of online comments' influences on the consumer behavior



- X: The characteristics of online reviews
- Y: Consumers' purchase intention
- Z: Risk perception

- E2: The length of the reviews
- E3: The richness of the description
- E4: The risk of quality
- E5: The risk of service
- E6: The risk of logistics
- E7: The credit score
- E8: The degree of satisfaction
- E9: Purchase intention
- E10: Likable degree

DATA COLLECTION AND ANALYSIS

Data Collection

In this paper, we apply data mining technology to collect the data that we need. We use the LocoySpider as the mining tool, the collection objects are the online comments of Taobao, then we catalogue the useful data. Because Taobao has a huge amount of data, we randomly selected a kind of clothes to analyze. One of the selection criteria is bigger volume, the other is if it has large amount of reviews. The large volume reflects a trend of taste of the consumers. To some extent, it can ensure the quality and quantity of comments. At the same time, if the product has many reviews, we will have more chance to choose the reviews. We randomly selected 25 pages to study from the large amount of comments. There are 20 articles per page, and we collect a total of 500 comments. Then we use Likert 5 to organize the reviews and analyze it with SPSS17.0 and AMOS17.0.

Data Analysis

In this article, we use SPSS17.0 to analyze the data of 10 indexes in order to measure the reliability of the inspection item, the Cronbach's α value concluded is shown in Table 2.

Table 2. The measurement of reliability

Variables	The number of the index	Cronbach's α
X	3	0.686
Z	3	0.609
Y	3	0.824

From Table 2, we can see that Cronbach's α is bigger than 0.6, it shows a good internal consistency, so the data has strong reliability.

As Table 3 shows, the value of KMO is bigger than 0.6, so it is acceptable. Bartlett test of sphercity is used to judge the data's normal distribution of multiple abnormal or to check whether the correlation

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

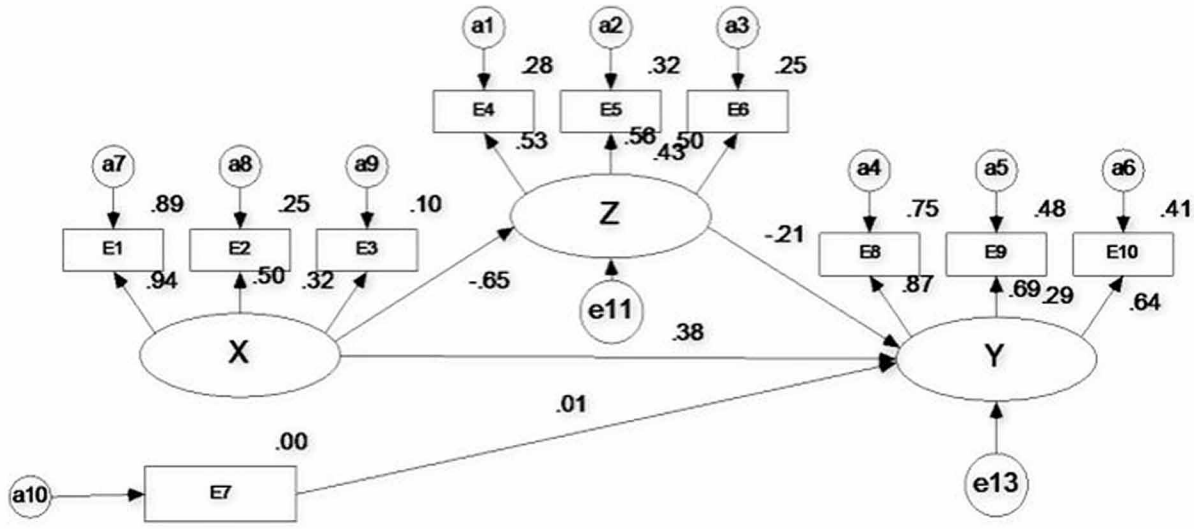
Table 3. KMO & Bartlett

Measurement Index	KMO	Bartlett test of sphercity	df	Sig.
X	0.615	278.834	3	0.000
Z	0.623	170.061	3	0.000
Y	0.721	564.604	3	0.000
Total	0.737	1355.176	45	0.000

Table 4. The fit of the model parameters

Test Rating	The estimated value	The suggestive value
Goodness of Fit Index (GFI)	0.964	>0.90
Adjusted Goodness of Fit Index (AGFI)	0.924	>0.90
Normed Fit Index (NFI)	0.932	>0.90
Comparative Fit Index (CFI)	0.949	>0.90
Root Mean Square Error of Approximation (RMSEA)	0.072	<0.08

Figure 2. The path coefficient of AMOS



coefficient matrix is suitable for factor analysis or not. Because the value Sig. is less than 0.05, it is suitable for factor analysis.

We use AMOS17.0 to analyze the fit of the model, GFI, AGFI, NFI, CFI are all bigger than 0.9, RMSEA is 0.072, it is smaller than 0.08, so the fit of the model is very good. The result is shown in Table 4.

At last, we use AMOS17.0 to make the hypotheses testing, and the result is shown in Figure 2.

As it is shown in Figure 2, the direct effect of comment features to purchase intention is 0.38, which is obvious. The direct effect of comment features on risk perception is -0.65, which is obvious. The direct

Table 5. The results of the hypotheses

Hypothesis	Content	Result
H1	The risk perception has negative influences on consumers' purchase intention.	Favorable
H2	The characteristics of online reviews have negative influences on consumers' risk perception.	Favorable
H3	The characteristics of online reviews have positive influences on consumers' purchase intention.	Favorable
H4	The characteristics of online reviews can affect consumers' purchase intention through the risk perception.	Favorable
H5	The credit score has positive influence on consumers' purchase intention.	Unfavorable

Table 6. Standardized total effects (Group number 1 - Default model)

	X	E7	Z	Y
Z	-0.654	0.000	0.000	0.000
Y	0.519	0.013	-0.206	0.000
E3	0.316	0.000	0.000	0.000
E2	0.503	0.000	0.000	0.000
E1	0.944	0.000	0.000	0.000
E10	0.332	0.008	-0.132	0.639
E9	0.360	0.009	-0.143	0.693
E8	0.449	0.011	-0.178	0.866
E6	-0.326	0.000	0.498	0.000
E5	-0.369	0.000	0.564	0.000
E4	-0.349	0.000	0.534	0.000

effect of risk perception on purchase intention is -0.21. The influence is also obvious. So, the model of comment features' influences on purchase intention is incomplete mediation.

From Figure 2, we can see that in addition to H5, the rest of the hypotheses are all established, it is shown in Table 5.

From Table 6, we can see that the total effect of comments' characteristics on purchase intention is 0.52. Because the direct effect of comments' features on purchase intention is 0.38 (as it is shown in figure 3), the indirect effect of comments' characteristics on purchase intention is 0.19. So the direct influence is greater than the indirect effect. Sellers should pay more attention to the direct effect of reviews' characteristics on consumers' purchase intention. We can formulate a series of measures based on the online reviews, which will work well. The most influential variables of the online reviews' characteristics is the strength of the reviews' tone. The sellers should guide reviewers in order to increase the frequency of modal particle that they use in the reviews, such as good, very good, and so on. It can reassure consumers and increase their confidence in shopping online. The depth of online reviews is important as well. Online marketers can take actions to encourage reviewers to make reviews with more words. There are many measures, such as cashback, daily deals, and so on. For the richness of comments, merchants can survey what the consumers focus on to set necessarily review dimensions,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

then it can increase persuasive comments. In this article, we take clothes as an example to analyze. The consumers concern many aspects of the clothes, such as whether it has chromatic aberration, whether it lose its color, workmanship is good or not, and so on. So the sellers can transform the variables into the form of Likert 5. In this way, it is not only taking consumers conveniences to make online reviews, but also making consumers more conveniences to find what they care about when they go shopping online.

As an intermediate variable, risk perception is also very important which the effect on purchase intention is -0.21. As a psychological perception, risk perception is a kind of subjective feeling. The only thing we can do is to abate it. Risk perception of shopping online usually comes from these factors, such as the logistics, the quality of the products, and so on. Online merchants can make the delivery faster or cooperate with the reputable logistics companies in order to reduce the risk of logistics. If the service staffs answer consumers' questions in time, their service attitude and the rationality of their suggestions will directly affect the purchase intention of consumers. So, they can train the consumer-service staffs. The speed of returns should be faster, their service attitude should be enthusiasm. Then the risk perception will reduce easily. At the same, we should set separately dimensions based on logistics, service and the quality of the products. And we should guide the reviewers to make reviews from the strength of reviews' tone and the depth of reviews in order to reduce the risk perception of consumers.

In contrast to the theoretical hypotheses, credit score has little impact on purchase intention, which can be neglected. This is because some Internet consumers don't want to post online comments. There are many factors can affect whether consumers make online reviews. Some consumers with high credit score may not want to spend much time posting online reviews because of the high time costs. At the same time, some of the comments published by the reviewers who are newcomers or inactive ones. These reviewers will be more careful when they make online comments. So, the comments will be more comprehensive, the content will be with high quality and the reviews will have a certain reference value. These factors cause inconsistent with the theoretical hypotheses.

CONCLUSION

In this paper, we choose online reviews of clothes in Taobao as the research object. We analyzed the online reviews' influences on consumers' purchase intention. The results prove that the factors that affect consumers' purchase intention include the depth of online reviews, the strength of the reviews' tone, the richness of the description, the credit score of reviewers. Meanwhile the risk of quality, logistics and service will also impact consumers' purchase intention. So online sellers should not only find their own shortcomings that consumers provide in online reviews and correct it, but also guide the consumers to make online reviews in a positive way. So, the credibility of online comments will be higher. It will reduce the risk perception of consumers more easily and increase the reliability, which will become a virtuous cycle.

Online merchants can encourage consumers to make online reviews through the method of giving cashback, offering a discount, providing coupon. They should fully tap the potential of reviewers' ability of making comments and encourage the reviewers to post the comment seriously. At the same time, they can set up review template to guide consumers to make comments. Towards the characteristics of reviews, they can set the number of words requirements on reviews. But today's comments for 15 words is too short to make comprehensive evaluation for goods. The number is more suitable between 25 and 30. If too short, it will appear to be elaborate unconvincing. The strength of tone represents the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

subjective feeling of the reviewers. Based on the 5 scales of overall comments, the online merchants can set 5 scales for specific comments. It is not only easy to post review, but also convenient to observe the results. The richness of the description refers to the dimensions of online reviews that describe the goods or services. From the richness of the description, consumers can understand the performance of the goods more clearly. These performances are needed most by the consumers. We should guide consumers to make reviews from the aspects of the service, the quality of the product, logistics, and so on. So that we can reduce the risk perception with setting scale level 5 of logistics and service in order to make convenient evaluation. And we can also encourage the consumers who have high credit scores to make reviews. Because their influences on network consumers' purchase intention are bigger than the ones whose credit scores are low.

So, better evaluation system must be established. For example, nowadays, the index of measurement only made a totally evaluation, so we can make 5 scales to measure the speed of shipment, the speed of transport, the speed of the last delivery, the attitude of the deliveryman, the logistics partners' public praise, and so on. The detailed system can make better work to affect the consumer behavior. In the aspect of quality risk, the online merchants can take the most important index to measure. If the product is clothes, we can make the 5 scales to measure the color different of it, the workmanship, the fabric, the size, and so on. In this way, the online review will do a better work.

Reviewers can also make comments on freedom according their shopping experiences to increase the comprehensive nature of the comments.

This study is not only good for online sellers, but also can helps consumers to reduce their search costs. Network consumers can determine the quality of the goods according to the features of online comments and the credit of reviewers. It can avoid the interference of the comments with low credibility on consumers' shopping decisions. In this way, network consumers can reduce the time of searching information, so they can search for the goods in less time, and buy suitable products faster.

ABSTRACT

The rapid penetration of smartphones and consumers' increased usage/dependence on mobile applications (apps) has ushered favorable opportunities for retailers as well as shoppers. The traditional brick-and-mortar as well as online retailers must attract shoppers to use mobile shopping apps. For this, it is pertinent for retailers to predict users' continuous intention to buy through apps. To address this question, the present study has applied four prominent binary classifiers - logit regression, linear discriminant analysis, artificial neutral network and decision tree analysis to develop predictive models. Findings of the study shall help the marketers in accurately forecasting shoppers' buying behaviour. Various indices have been used to check the predictive accuracy of four techniques. The outcome of the study shows that the models developed using decision tree analysis and artificial neutral network provide better results in predicting consumers' continuous intention to buy through app. Based on the findings, the paper has also provided implications for the retailers.

1. INTRODUCTION

Of late, mobile applications have become a preferred choice for many consumers in various domains like entertainment, food ordering and delivery, banking, home service, etc. Shoppers' experience through mobile apps is highly different from that through the mobile phone's browser (Natarajan et al., 2017). Providing a personalized user-friendly environment for mobile commerce (Tarasewich, 2003), mobile apps involve many activities, which are not present in mobile browsing through web pages. These include researching products, comparing features, reading reviews, tracking order, getting rewards and loyalty points, retrieving saved coupons, etc. (Natarajan, et al., 2017).

When users download mobile applications in their mobile device, they invite the retailers for communication. Once the application is downloaded, retailers can interact with consumers by sending new product launch offers, promotion offers, reminders based on previously searched products and many other marketing efforts for influencing the attitude of users (Natarajan, et al., 2017). The app providers focus on increasing sales and profits by providing shoppers with more buying opportunities by means of advertising new products and retaining existing customers (Kim et al., 2017). For all this, it becomes pertinent for retailers to comprehend consumers' attitudinal and behavioral intentions. Existing studies on mobile commerce have observed that the intention to buy a product depends on perceived usefulness, perceived ease of use and perceived enjoyment (Agrebi and Jallais, 2015; Chong, 2013; Faqih and Jaradat, 2015; Wang et al., 2015).

Retailers attempt to forecast their sales by predicting shoppers' future intentions to buy, which is based on their previous buying behaviour. However, in case of e-commerce (or m-commerce), it is extremely difficult to predict sales because of its growth pattern, which is non-linear; unpredictable penetration of smartphones; and shoppers' unplanned purchasing behaviour. Nevertheless, in order to survive the competition, online retailers and mobile app providers must predict shoppers' continuous intention to buy.

Extant literature on online shopping is available in the context of websites (Childers et al., 2001, Holzwart et al., 2006; Hong et al., 2014; Hsu et al., 2006; Park and Kim, 2003), shopping through mobile browser (Agrebi and Jallais, 2015; Chong, 2013; Faqih and Jaradat, 2015; Wang et al., 2015). However, very few studies have been carried out in the context of shopping through mobile apps (Kim et al., 2017; Natarajan, et al., 2017). These two quantitative studies have measured the possession and intention to use and purchase using mobile apps. The qualitative study by Fuentes and Svingsted (2017) has determined recent practices adopted by shoppers owing to the introduction of mobile applications. However, existing studies have not examined shoppers' post adoption behaviour, more specifically their continuous intention to use the mobile apps for shopping.

To fill this research gap, the present paper is an attempt to use four binary classifiers - logistic regression, linear discriminant analysis, artificial neural network and decision tree analysis, for predicting shoppers' continuous intention to buy through mobile apps. This study endeavors to develop predictive models based on prominent antecedents influencing consumers' continuous intention to buy using mobile apps. Eight antecedents - performance expectancy, effort expectancy, price and discount, layout, atmosphere, user experience, user satisfaction and 'pay-more-get-more' promotion, have been considered as independent variables, while continuous intention to buy using mobile app is the dependent variable. Thereafter, the study compared the predictive ability (effectiveness) of these techniques in identifying the true positive cases using indices like accuracy, precision, likelihood ratios, diagnostic odds ratio and Younden's index.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

The rest of the paper has been organized as follows. The following section discusses the review of literature pertaining to the factors that have influence on continuous intention to buy, and four forecasting techniques used in the study. After this, research methodology used has been explained along with the deliberation on the results arrived. The subsequent part of the paper presents discussion, conclusion and limitations of the study.

2. LITERATURE REVIEW

2.1. Performance Expectancy

According to Pikkarainen (2004), performance expectancy is "a degree to which using a technology will provide benefits to a consumer in performing certain activities." It has been posited that acceptance of technology increases if consumers find it easy to use. A study by Parboteech et al. (2009) on website characteristics has measured the potential link between perceived usefulness and buying intention. In the context of mobile applications, Hew et al. (2015) observed a direct relationship between behavioral intention and usage of apps. Owing to being need specific and fast performance, shopping on mobile apps is different from website. Hence, the app-based shopping is considered as an extended and easier version of online shopping. It is expected that as shoppers obtain pleasure from the internet-based shopping, their satisfaction increases, which motivates the shoppers to continuously use the system. In the study, Deng et al. (2010) observed a decline in shoppers' satisfaction from a system when it provides experiential and emotional values. On the other hand, when the system provides functional values, shoppers' satisfaction increases.

2.2. Effort Expectancy

Effort Expectancy (EE) is defined as "the degree of ease associated with consumers' use of technology" (Venkatesh, 2012). The study by Pynoo et al. (2011) suggested that the perceived ease of use is like effort expectancy. EE is one of the significant variables prompting shopper's behavioral intention (Hew et al., 2015; Venkatesh, 2012). The consumer's emotions trigger positively as well as negatively, when it is easy to use (Ethier et. al, 2006), and impulse buying has direct impact through these emotions (Verplanken and Herabadi, 2001). Many studies on mobile apps and websites have speculated that the touchscreen quality of the mobile device makes it easier than the other websites (Chang et al., 2012; Islam et al., 2010). The touch panel provides direct control on the touch and makes it easy to use (Brasel and Gips, 2014; Leong et al., 2013). Shen and Chiou (2010) posited that shoppers' intention to adopt internet base shopping depends on the amount of effort and energy expended by them while going through the system.

2.3. Price and Discount

Considered as a significant factor that influence shoppers buying behaviour, low price induces feeling among buyers that they are expending less than the originally planned amount (Stern, 1962). Consumers' mood becomes heightened with the unexpected saving; this increases the number of unplanned purchases (Heilman et al., 2002). According to Verhagen and Dolen (2011), the price of the product and discounts offered on the portal induce hedonic and utilitarian behaviour, and as per Hardesty and Bearden (2003),

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

such behaviour stimulates buying behavior. In the context of shopping through mobile app too, price and discount factors can be interpreted as influencers of impulse buying.

2.4. Layout and Atmosphere of App

Atmosphere has been defined as "the conscious designing of space to create certain buyer effects, specifically, the designing of buying environment to produce specific emotional effects in the buyers that enhance purchase probability" Kotler (1973). Marketers design web interface for attracting and enticing shoppers to utilize the web atmosphere (Eroglu et al., 2001). The web atmosphere creates pleasure and arouses desire among consumers (Eroglu et al., 2001). The ambient factors related to the atmosphere have a positive effect on shoppers' behavioral intention (Sherman et al., 1997) and all these have a potential to trigger a desire to purchase impulsively (Eroglu and Machleit, 1993).

In the online context, the design factors are considered as more influencing and visible than ambient factors (Grewal and Baker, 1994). Studies like Wells et al. (2011) and Verhagen and Dolen (2011) have examined the association between website design and shoppers' impulse buying behavior. Sherman et al. (1997) observed that range and visibility of products on web portals influence shoppers and induce their urge to buy. The study by Wu et al. (2013) has noted that the web layout positively affects consumers' purchase intention by enhancing their attitude towards the website. The study has also observed the positive effect of atmosphere on impulse purchase intention.

2.5. User Satisfaction Through Shopping App

As per Olaru et al. (2008), user satisfaction helps "customers evaluate future purchase intention based on the value obtained from episode/contacts, with relationship benefits being a proxy for expectations of future benefits." In the context of online shopping, Khalifa and Liu (2007) examined the relationship between customer experience and customer satisfaction, which leads to purchase intention. On the other hand, the study on branded mobile app by Alnawas and Aburub (2016) noted that the mobile apps make consumer up-to-date, smarter, improve their prestige among peers, lightens their mood, make them feel the part of a community and promote value. All these factors influence their satisfaction towards the mobile platform, which finally shapes future purchase intention. Thus, consumer satisfaction is the key factor that influences buying behaviour (Wu et al., 1970). Agrebi and Jallais (2015) examined shoppers' satisfaction achieved through mobile commerce and its effect on their continuous intention to use. Similarly, study by Hung, Hwang and Hsieh (2007) observed a positive and significant correlation between level of satisfaction and repurchase intention. According to Natarajan et al., (2017), as the performance of the mobile app fulfills consumers' expectation, they tend to develop positive attitude towards the app, which results in satisfaction with the app.

2.6. User Experience with Shopping App

Consumers interact with the environment and surroundings for the sake of growing learning experience (Li et al., 2002). Hassenzahl (2008) defined user experience as "a momentary, primarily evaluative feeling while interacting with a product or service. Good user experience is the consequence of fulfilling the human needs for autonomy, competence, stimulation (self-oriented) through interacting with the product or service (i.e. hedonic quality)." Keng et al. (2011) categorized online experience in two

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

categories - direct product experience and indirect product experience. Direct product experience is the information acquired directly from the website. On the other side, indirect web experience contains interaction or willingness to move, which involves shoppers' spending time for reading text and looking at graphics (Huang, 2003). Kahn and Isen (1993) determined the relationship between mood and emotional experience that leads to impulsive buying. Considering mobile app as an extended version of an online shopping website, user experience through app may also influence shoppers' purchase intention.

2.7. 'Pay-More-Get-More' Promotion

According to Yoon and Vargas (2010), almost all the retailers (both e-commerce and traditional brick-mortar stores) attract shoppers by using promotional offers like 'pay-more-get-more' to increase their sales. These offers are given for a very small period of time or during the preliminary installation phase (in case of mobile app) or also when consumers have undertaken a certain amount of purchases. Homburg et al. (2010) suggested that whenever shoppers go to a retailer, they constantly create psychological budgeting that would help them in planning future purchases. Promotional offers such as rebates, bundled offers, buy-more-get-more, etc. influence shoppers' psychological budgeting. These offers tend to increase shoppers' purchase intention that can lead to continuous impulse buying intention (Pentina et al., 2016).

3. TECHNIQUES USED FOR FORECASTING CONTINUOUS IMPULSE BUYING

The following section presents a brief description of select four modeling techniques that have been used for developing analytical models.

3.1. Logistic Regression (LR)

Logistic regression also known as logit model or logit regression is used for determining the connection between independent variable(s) and a dependent variable (categorical variable) (Freedman, 2009). The logistic regression has been used to solve the problem, which has binary or dichotomous dependent variable with two existing categories (Walker and Duncan, 1967). LR is a special case of regression wherein the dependent variable is a binary variable and is influenced by a set of metric independent variables. One of the major advantages of using this technique is that there is no need to satisfy the assumptions of linearity, normality, etc. for the variables. The logistic regression technique has been frequently used in marketing to examine the influence of price tags, to determine the appropriate promotional campaign media, to purchase a product on specific price, identifying the channel for distribution, etc. (Bucklin and Gupta, 1992). While Yeung and Yee (2011) suggested that this technique could be used for predicting consumer purchase propensity, Lee et al. (2012) used this technique for forecasting sales of fresh food.

3.2. Linear Discriminant Analysis (LDA)

Linear discriminant analysis (LDA) is a technique that has been used in "pattern recognition and machine learning" in order to describe a linear combination of variables that help in discriminating two or more classes of patterns (Fisher, 1936). The statistical method used in measuring the group or classification of an object belongs to a group, based on its essential features. It explains the values of continuous

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

independent variable as a categorical variable. The technique may have two objectives - descriptive or predictive: it evaluates the acceptability of classification with the given group membership of an object and it allocates objects in one of the classifier. Linear discriminant analysis has been used for delineating the factors, which differentiate one type of customer to other and to draw perceptual maps. With the help of discriminant analysis, Baglione (2014) identified the perception of undergraduate students towards smartphone and its uses. Julian et al. (2015) determined the distinctive dimensions of the relationship marketing like loyalty program, customization, personalization, customer service, and store community.

3.3. Artificial Neural Network (ANN)

The artificial neural network technique is one of the most widely used techniques for measuring the non-linear relationship among all the factors. This technique has been used in numerous fields like marketing, health and medicine, accounting and finance, and manufacturing. Haykin (2001) defined artificial neural network technique as "a massively parallel distributed processor made up of simple processing units, which have a neural propensity for storing experimental knowledge and making it available for use." The basic working of the neural network is similar to the biological brain and its processing. The main features of this computational system are based on the large number of simple processing neurons and a large number of weight connector among the components. The neural network technique tends to provide better prediction results in case of estimating market reaction based on consumer data as compared to that of other techniques (Hruschka, 1993). Chiang et al. (2006) and Prashar et al. (2018) stated that the predictive model developed by using neural networks has greater prediction power as compared to other binary classifiers like logistic regression and linear discriminant analysis. Even though ANN suffers with the problem of over-fitting of training data set, Guido et al. (2011) and Prashar et al. (2015) suggested that this technique is better suited for forecasting because the prediction of response rate is good.

3.4. Decision Tree

Decision tree analysis is a popular data mining method. Mainly used for classification and prediction, this technique systematically analyzes the abundant data source and identifies hidden valuable relationship between the variables (Chen et al., 2003; Chou, 1991). Since decision tree analysis is robust to the data, scales and population distribution, it has been extensively used in various areas as compared to other mining techniques (Berry and Linoff, 2000). In this technique, decisions are made at each node in the form of top-down tree structure. When the analysis of the data starts, each data point flows through the tree in a path determined by a sequence of tests till the time it reaches to the terminal node or leafs of the tree. At this terminal, it gives the result either in the form of continuous or discrete value. The classification tree determines and measures the membership of the cases with the dependent variable based on one or more predictor variables.

4. RESEARCH METHODOLOGY

To predict the continuous intention of shoppers to buy using mobile app (Amazon.in), a cross-sectional study was conducted with the following steps:

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.1. Step I: Construction of Survey Instrument

Comprehensive review of past literature on adoption and continuous usage of mobile apps for shopping was undertaken to gain insights related to mobile app-based consumer behavior. This resulted in the identification of eight antecedents that have influence on continuous intention to buy through a mobile app. These eight factors were performance expectancy, effort expectancy, price and discount, layout and atmospheric elements of an app, user satisfaction through shopping app, user experience with the app and promotional scheme 'pay-more-get-more.' It was decided to use the existing validated scales for these constructs. Refer to Table 1.

Table 1. Antecedents and Respective Scales

S. No	Construct	Study	No of Items
1	Performance Expectancy	Venkatesh (2012)	3
2	Effort Expectancy	Venkatesh (2012)	3
3	Price and Discount	Venkatesh (2012)	3
4	Layout of App	Wu et al. (2013)	4
5	Atmospheric Elements	Wu et al. (2013)	4
6	User Satisfaction Through Shopping App	Alnawas and Aburub (2016)	4
7	User Experience with the App	Prashar, Parsad and Vijay (2016a)	4
8	'Pay-more-get-more' Promotion	Yoon and Vargas (2010)	10

These thirty-five items were converted into statements, and the respondents' agreement for each of these statements was measured using seven-point Likert's scale, where 1 and 7 represented 'strongly disagree' and 'strongly agree' respectively. For measuring the output variable continuous intention to buy through a mobile app, the respondents were asked whether they will continue to buy using the mobile shopping app (here Amazon.in). The response to this question was solicited through two alternatives – Yes and No. The instrument also had few questions related to the respondents' demographics. The instrument was pre-tested with sixteen students pursuing their doctoral degree in management. Upon their feedback, small modifications were made in the language.

4.2. Step 2: Data Collection

Since, it has been reported that the majority of the mobile shopping app users are below the age of thirty years (Statista, 2017), it was decided to collect data from college students and working executives. The questionnaire was loaded on Qualtrics and using the convenience sampling technique, the link was mailed to the respondents. The data was collected during the three months period of May-July 2017. In all, responses from 495 respondents were received, of which 357 reported Amazon.in to be their preferred mobile shopping app. After removing partially filled instruments, responses from 297 shoppers were used for further analysis.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

4.3. Step 3: Modeling and Analyzing

After randomizing, the data set from 297 respondents was separated into two segments - training set and testing (validation) set. Data from 214 respondents (72.05%) was used as training set to formulate a predictive model. Four binary analytical techniques – logistic regression, linear discriminant analysis, artificial neural network and decision tree analysis were applied using SPSS. The remaining 83 (27.95%) respondents' data was used as a test set to validate the models built. For evaluating the functioning of the algorithm undertaken, contingency/ confusion matrix is prepared. As per Table 2, possible combinations are:

Table 2. Contingency Matrix

	Test Outcome Negative (Hold-out Sample = 0)	**Test Outcome Positive (Hold-out Sample = 1)**
Condition Negative (Prediction = 0)	True Negative (TN)	False Positive (FP)
Condition Positive (Prediction = 1)	False Negative (FN)	True Positive (TP)

5. DATA ANALYSIS

To examine the effectiveness of the models developed using the four binary classifiers, the respective contingency matrices were drawn, as shown in Table 3.

Since, one of the objectives of the present paper is to identify the best predictive technique, it is imperative that the results obtained from four techniques are compared using select comparative indices. There are many indices that can be used to show how well the predictive models, developed by the

Table 3. Contingency Matrix

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Discriminative Ability

Technique	Accuracy	Precision	Sensitivity	Specificity	LR+	LR-	DOR	Younden's
LR	0.831	0.869	0.923	0.5	1.85	0.15	12.33	0.423
LDA	0.719	0.866	0.825	0.6	2.06	0.29	7.1	0.425
ANN	0.843	0.90	0.889	0.7	2.96	0.158	18.73	0.589
DTA	0.807	0.943	0.793	0.85	5.28	0.24	22	0.643

binary classifiers, forecast the outcome (continuous intention to buy through a mobile app). The most popular indices are accuracy, precision, sensitivity, specificity, likelihood ratios, diagnostic odds ratio and Younden's index. These indices help in determining the discriminative capability of forecasting techniques (Refer Table 4 for the results).

The index accuracy reflects the model's ability in making correct predictions. From Table 4, it is observed that artificial neural network has the highest accuracy level (0.843). This suggests that out of every hundred predictions made by the ANN model, nearly 84.3% turn out to be correct. Logistic regression closely follows ANN with 83.1% accuracy. Precision is defined as the proportion of correctly predicted positive cases. From the results, it is noted that the decision tree has the highest precision (0.943), followed by ANN. The percentage of true and false cases that are correctly recognized are known as sensitivity and specificity respectively. Logistic regression recorded the highest value for sensitivity (0.923) and decision tree had the highest specificity value (0.85).

Besides these regular indices that are used for measuring the discriminative ability of techniques, other prominent indices include likelihood ratios, DOR and Younden's index.

- **Likelihood Ratios:** Likelihood ratio suggests the fact that not all true (or false) expectations are true positive (or negative) predictions. There would be some app users with positive prediction, but they might not buy. In the present study, it indicates the ratio of mobile app shoppers who have continuous intention to buy on shopping app to that of shoppers with no such preference. The ratio of positive test outcomes (LR+) states the likelihood of occurrence of positive prediction result among app users having continuous intention to buy on shopping apps as against those without any such intention. Greater values of LR+ reflect that the model is appropriate for predicting shoppers who have continuous intention to buy using mobile shopping apps. It is suggested that a good predictive model should have LR+ > 10. On the contrary, LR- (likelihood ratio for negative test) signifies the ratio of false negative result to total negative result. Any good forecasting model should have LR- < 0.1 (Šimundić, 2008). The lesser the LR- value, the better is the predictive ability of the model.
- **Diagnostic Odds Ratio (DOR):** The ratio of LR+ and LR-, DOR's values vary between zero and infinity. When values are greater than one, it indicates the effectiveness of the model developed by a predictive technique. The higher values of DOR represent the goodness of the technique (Glas et al., 2003; Šimundić, 2008). In the present study, DOR is the probability of the test being positive when the sampled shopper turns out to have continuous intention to buy as against the likelihood of the test being positive if the same shopper doesn't have intention to buy continuously.
- **Younden's Index:** This index is extensively used for determining a predictive model's effectiveness and for comparing many predictive models at a time (Šimundić, 2008). Younden's index is

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

calculated by deducting numeral one (1) from the sum of sensitivity and specificity. If the final value is zero or near zero, it represents poor accuracy; whereas when the Youden's index is equal to one it indicates the goodness of the model (Šimundić, 2008).

6. DISCUSSION

The existing research on mobile apps have mainly focused on the pre-adoption phase, exception being few studies related to stickiness (Furner et al., 2014; Kim et al., 2015) and app recommendation (Xu et al., 2015; Yan and Chen, 2011). Regarding studies related to shopping apps, adoption of such apps is the key topic (Kim et al., 2017; Natarajan et al., 2017). The present research is a pioneer attempt to model and predict mobile users' continuous intention to buy using shopping app. To the best of the researchers' knowledge, none of the existing studies have attempted to predict shoppers' continuous intention to buy. The paper has examined the influence of eight antecedent factors on continuous intention to buy using shopping apps by developing four predictive models. Finally, the study predicts the discriminative ability of four predictive models using various indices.

Accuracy measures the strength of a classifier in correctly identifying or excluding a condition. It reflects the model's ability in making correct predictions. From Table 4, it is observed that artificial neural network technique has the highest accuracy level, followed by linear regression. This is in line with the findings of Prashar et al. (2016b) that has been conducted in the context of impulse buying. Linear discriminant analysis has the least value of accuracy among the four techniques. Precision, on the other hand, measures the proportion of all correct positive cases. Decision tree analysis has the highest precision value, followed by ANN. Thus, the first two indices have identified two different techniques as superior in contrast to the other techniques. This is quite intriguing, since it is expected that all the indices must conclude superiority of a single predictive technique. Therefore, to check for superiority among the predictive techniques, various other indices were calculated and compared.

Sensitivity reflects the real true positive outcomes of a model. From the findings, it is observed that logistic regression has the highest value, indicating its superior ability to correctly identify the shoppers having continuous intention to buy. The other three techniques had values lower than 0.9. On the other hand, specificity helps in identifying the real negative outcomes. This indicates the model's ability to correctly identify the shoppers who are not likely to continue shopping through the mobile app. This index helps in eliminating the false alarm. The model derived using decision tree analysis has a specificity value of 0.85, which is higher than the other three predictive models. This value suggests that the decision tree model will be able to recognize eighty-five percent of all the negative cases that are negative.

Again, with the two differing results for sensitivity and specificity, it was decided to calculate the diagnostic odds ratio (DOR), which is the combination of the results of sensitivity and specificity. All the four techniques in the present study had DOR values greater than one. However, with the value of 22, decision tree analysis showed the best result, followed by artificial neural network technique (18.73).

With the positive likelihood ratio (LR+) score of 5.28, decision tree analysis is found to be a better technique for predicting shoppers who have continuous intention to buy using apps as compared to the other three techniques. Though, the score is more than five, which reflects that it is a good model for predicting shoppers' continuous intention to buy, but the value is much less than the boundary value of ten, indicating that none of the techniques is a strong predictor. The negative likelihood ratio (0.15) of

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

two models - logistic regression and artificial neural network technique indicate the superiority of these techniques over other two models. The former outcome cements the finding of Prashar et al. (2016b).

Combining the results of these four indices, it can be concluded that the predictive model developed using decision tree analysis is most effective in predicting mobile users' continuous intention to buy using shopping apps. Finally, the discriminative ability of four techniques is summarized by Younden's index. From the findings, it is noted that two techniques have scored more than 0.5 - decision tree analysis (0.643) and artificial neutral network technique (0.589). This reflects the goodness of these two models in predicting false negative and false positive results.

With the highest value in most of the indices - precision, specificity, LR+, DOR and Younden's index, the predictive model developed using decision tree analysis emerges to be the most appropriate one. This model is successful in predicting both high level of true positive and true negative cases. However, the sensitivity value for decision tree analysis is the least, which reflects its inability to identify the true positive cases for measuring the continuous intention to buy. Remaining indices (accuracy; LR-) are reflective of comparatively better result. The predictive model developed using artificial neural network technique had the maximum accuracy value among the select techniques. This technique ranked second in the remaining indices (precision; sensitivity; specificity; LR+; LR-; DOR; Younden's index). Overall, this model shows a good result for both the true positive and true negative cases.

The third technique, logistic regression had a maximum value for two indices -sensitivity and LR. This shows that the model's predictive power is higher than other techniques and is capable of predicting true positive cases. On the other hand, it had minimum values for specificity, LR+ and Younden's index. The last technique, linear discriminant analysis had the lowest value in most of the indices (accuracy: 71.9%; precision: 0.866; sensitivity: 0.825; LR-: 0.29; DOR: 7.1) except specificity (0.6), LR+ (2.06) and Younden's (0.425) indices. These values indicate that this technique is not very good for predicting continuous intention to buy as compared to the other techniques.

Accuracy of prediction should not be the only criteria for selecting any forecasting technique. According to the literature in the field of medical science, the result of any diagnostic test depends upon the discriminative ability of each of the predictive model. Therefore, linear discriminant analysis and logistic regression are rejected as not good techniques for developing predictive models. Considering all the techniques, based on their discriminative ability, the study observed that decision tree and artificial neutral network techniques are good models for predicting mobile shoppers' continuous intention to buy. The app provider (retailer) can use these two techniques for predicting consumers' continuous intention to buy. For the app provider, retaining existing customers is much more important than getting new customer from the competitive market. Also, it is important for the app provider to get more true positives results than false negative outcomes. Therefore, artificial neural network technique and decision tree analysis may be preferred over other two techniques.

This is the pioneer study, which has compared decision tree and three other techniques in the domain of consumer buying behaviour in the context of mobile shopping application. The eight variables estimated in this study, contribute as an input variable for forecasting shoppers' continuous intention to buy from the same platform. In the context of buying using mobile apps, the shoppers' behaviour frequently changes because of many options/platforms. To overcome such situation, the retailers must use predicting techniques for forecasting high false negative and low false positive. Based on the accuracy value, the model may look perfect. The lower LR- value indicates that the model is equally good in predicting non-purchaser (ANN and LR). The study will reduce the risk of failure for the mobile retailers because of ill preparedness (attentiveness) in terms of technology capability.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

7. CONCLUSION

This paper contributes to app providers and retailers for predicting consumers' continuous buying behaviour. In the study, four predictive techniques have been used for comparing their forecasting ability with regard to consumers' continuous intention to buy through mobile apps. Accordingly, the technique(s) with better forecasting ability will play a significant role for app providers. Based on findings of four select binary classifiers and the objectives app developers seek, it can be concluded that predictive ability of decision tree analysis is comparatively better than the other techniques. The contribution of this study to the literature of mobile app-based buying behaviour incorporates the application of four predictive methods, using eight factors that affect continuous intention to buy, for forecasting actual buyers and comparing the techniques. Apart from predicting the shoppers' continuous buying behaviour, the results of this study can also be used to further investigate their buying pattern while using mobile application.

Like other survey-based studies, the present paper too has few limitations to be acknowledged. Over last few years, the e-commerce market has grown exponentially. Owing to shift in buying pattern from offline to online shopping, the consumer buying behaviour is also changing with time. Being cross-sectional in nature, the study has limitation in capturing the changes in buying behaviour. Undertaking longitudinal study design can overcomes this limitation. The study has been conducted in India, which limits generalizability of the findings. Cross-cultural studies must be undertaken across different markets (nations and consumers). The study has examined variables that affect consumer's intention to buy continuously. Exploratory study in the future shall help in identifying other significant variables that might influence shoppers' continuous intention to buy. The study is limited to students in the age group of 20-33 years. Future research can be widened bringing respondents from other age groups too. Similarly, other demographic and psychographic variables may be incorporated, and results assessed.

Chapter 30
Structural Equation Modelling of the Factors Influencing the Adoption of E-Commerce in Saudi Arabia:
Study on Online Shoppers

Abdullah Saleh Alqahtani
Deanship of Common First Year, Self-development Skills Department, King Saud University, Riyadh, Saudi Arabia

Robert Goodwin

Denise de Vries
Flinders University, Adelaide, Australia

ABSTRACT

This article presents findings from a study examining the diffusion and adoption of e-commerce in Saudi Arabia. Although the country has the largest and fastest growing information and communication technologies (ICT) sector in the Arab region, growth in e-commerce activities has not progressed at a commensurate rate. In general, e-commerce online shopping has not kept pace with the global growth of online retailing. The authors have conducted research to identify and explore key issues that influence e-commerce in Saudi Arabia in deciding whether or not to adopt online channels. As part of a larger research project using mixed methods, this article focuses on a quantitative analysis of responses obtained from a survey of the online shopping users in Saudi Arabia.

INTRODUCTION

The current era is often referred to as the Information Age, the Digital Revolution or the New Technological Revolution, depending on the commentator's perspective. These descriptors share the common characteristic of being based on the widespread adoption of computing and computer networking. The arrival of the internet and its rapid development into a globally ubiquitous resource has not only accelerated earlier computer driven change in business and society, but has also introduced additional major changes, including the use of the internet to facilitate, execute, and process business transactions (Delone & McLean, 2004). E-commerce allows businesses to share information, undertake transactions across networks and computer platforms, and work together over geographic boundaries (Berners-Lee et al., 1994; Kalakota & Whinston, 1997). It encompasses business-to-consumer, business-to-business, commerce-to-administration, customer-to-customer, and consumer-to-business (Goel, 2007) activities.

Online shopping is a form of business-to-consumer e-commerce (Nosrati, 2011; Nemat, 2011). It is more limited and exclusively describes the activity of selling and purchasing goods and services online via an e-store (Islam, 2012; Sharma, 2013). Xu (2012) noted that online shopping describes a single aspect of e-commerce; whereas e-commerce can represent any and all business activity conducted using an electronic medium (Ren, 2009).

In 2014 global e-commerce sales increased at a rate greater than 20% per year, influenced by four key factors: internationalization; the renewed popularity of e-commerce IPOs internationally; the rise of the continuously connected consumer; and consumers' ongoing desire to look, touch, and immerse themselves in brand experiences (ATKearney, 2015). Developed countries have already produced sophisticated online shopping malls and e-stores like Amazon and eBay, while the booming marketplace of China offers Ali-baba and Tencent. E-stores such as these are at the top of a list of global online sellers who are either already global brands or rapidly evolving in that direction.

BACKGROUND

As part of a very robust global market space, the Middle East is also experiencing rapid growth in e-commerce (MasterCard Online Shopping, 2014; Ecommerce Show, 2016). Online sales in the Middle East hit US$7 billion in 2014, the largest single share being in the UAE at $2.3 billion, followed by Saudi Arabia at $1.5 billion, and Egypt at $1.4 billion (Payfort, 2014). Some issues known to be particular challenges for e-commerce companies in the Middle East are: fear from users on loss of control; the desire to pay cash on delivery (C.O.D.); high returns and the negative impacts on cash-flow of C.O.D.; the unwillingness or inability of women to answer the door to unrelated male delivery men (PayPal, 2013; Quartz, 2015; The Economic Times, 2015). Setup costs, deployment issues to remote locations, and natural human resistance to change (Aladwani, 2003; Albadr, 2003; MCIT, 2014) are also slowing e-commerce provision and uptake.

Various researchers have sought to understand more fully the factors influencing technology adoption. They have considered factors at the individual level (Klopping & McKinney, 2004; Pantano & Di Pietro, 2012; Susanto, 2012), the firm level (Al-Qirim, 2008; Grandon & Pearson, 2004; Wymer & Regan, 2005) and the country level (Kevin Zhu, Kraemer, & Xu, 2003; Kevin Zhu & Kraemer, 2005). Several studies have concluded that cultural conditions in a nation are important influencers. In a comparison of the organisational cultures of 40 independent nations, Hofstede (Hofstede, 1980) argues that many of the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

differences in management styles and organisational practices of companies throughout the world can be related to differences in the collective mental programming of people in different national cultures. Dunphy and Herbig (1995) note that existing cultural conditions always determine whether, when, how, and in what form, a new innovation will be adopted.

Ein-Dor et al. (2004) conducted a four-country study that included Finland, Israel, New Zealand, and Singapore, and concluded that differences in culture, attitudes toward information and communication technology (ICT), and socioeconomic status all impact the adoption of e-commerce. Furthermore, infrastructure is critical to technology adoption. Molla and Licker (2005) found that in the late 1990s and in the first decade of the 21st century, developing regions lacked sufficient critical infrastructure. Internet speeds were slow. Internet service providers (ISPs) were expensive. And the regulatory environment was poor.

Early studies were conducted in the United States (Grandon & Pearson, 2004), the United Kingdom (Matlay & Addis, 2003), Canada (Sparling, Toleman, & Cater-Steel, 2007) and Italy (Scupola, 2003). Studies focussed on developing countries included Latin America (Davis 1999), Mongolia (Enns & Huff, 1999), Ukraine (Jennex & Amoroso, 2002), Malaysia (Mukti, 2000), Thailand (Wongpinunwatana & Lertwongsatien, 2003), Taiwan (Thatchera, Fosterb, & Zhua, 2006), South Africa (Cloete, Courtney, & Fintz, 2002; Moodley & Morris, 2004), Iran (Ghobakhloo, Arias-Aranda, & Benitez-Amado., 2011), Nigeria (Ma'aruf & Abdulkadir, 2012), and Sri Lanka (Kapurubandara & Lawson, 2006), and very recently on China, where there has been very rapid e-commerce growth (McKinsey, 2013). Most of the studies focused on the macro level (or global) constraints and explored the barriers and motivators in e-commerce adoption.

Several studies have investigated e-commerce in Saudi Arabia in a business-to-business (B2B) environment, while others have studied the business-to-consumer (B2C) context. Behavioural factors associated with e-commerce adoption have also been studied (Al-Gahtani, Hubona, & Wang, 2007; Al-Otaibi & Al-Zahran, 2003; Aleid, Rogerson, & Fairweather, 2010; Alfuraih, 2008; Rayed AlGhamdi, Drew, & Al-Ghaith, 2011; Rayed AlGhamdi, Drew, & Alkhalaf, 2012; Eid, 2011; Sait, Al-Tawil, & Hussain, 2004). Eidt (2011) conducted a study of determinants of e-commerce customer satisfaction, trust, and loyalty in Saudi Arabia. Al-Hudhair and Alkubeyyer (2011) examined both the level of e-commerce adoption in Saudi Arabia and attempted to identify factors that affected its adoption. None of the studies produced a comprehensive picture of the of level of e-commerce adoption in the B2C context, and there are clear gaps in identifying the behavioural factors related to e-commerce adoption. Nor have issues of infrastructure, culture, legislation, technical features, national awareness, or the national economy been examined in connection with the adoption of online shopping.

MAIN FOCUS OF THE ARTICLE

The goal of this study was to understand more fully the factors responsible for slow e-commerce adoption by online shoppers in Saudi Arabia and to develop a model to represent the influence of these factors on e-commerce adoption. The model will potentially assist professionals interested in services supported by ICT, the wider business community, and the government to develop and support comprehensive, effective, and sustainable strategies that promote e-commerce in Saudi Arabia.

CONCEPTUAL MODEL AND METHOD

Development of Hypotheses

A conceptual demand side model was developed to identify factors influencing e-commerce adoption in Saudi Arabia using a mixed model method. The basic concepts of the model were taken from several other models, including the theory of planned behaviour (TPB) (Ajzen, 1991), the decomposed theory of planned behaviour (DTPB) (Taylor & Todd, 1995), the technology acceptance model (TAM) (Davis, 1989), and the unified theory of acceptance and use of technology (UTAUT) model (Venkatesh et al., 2003). Each of these models has been developed and validated in Western nations.

To develop the conceptual model of the study, some hypotheses were initially developed related to the cultural context of Saudi Arabia. Culture in Saudi Arabia is tightly bound by Islamic belief and norms, and there are strict rules and regulations governing behaviour for different groups of people based on age and gender. To adequately address these issues, this study acknowledged that factors such as age, gender, and internet proficiency might influence the adoption of e-commerce. In addition to demographic and cultural factors, research has produced established theories on innovation diffusion and technology

Table 1. Independent constructs of the hypothetical model

Broad Area	Sub-Dimension/ Contrasts	Defining Aspects	Adopted From
Perceived characteristics of innovation	Payment security and convenience	Payment system available for online shopping and e-commerce transaction, their reliability and easiness for safe and secure transactions. 	E-commerce infrastructure	The website, cell phone application, internet facilities, access facilities and ease of use.	Rogers, 2003; Venkatesh et. al., 2003; Al-Ghaith et al., 2010; Gibbs & Kraemer, 2004
	Delivery system efficiency	Product delivery facility, maintaining schedule, cost of delivery, effectiveness of delivery system, delivery geographic coverage.	Kshetri, 2008; Hawk, 2004; Bayles & Bhatia, (2000); Rutter & Southerton, 2000; Rogers, 2003; Taylor & Todd, 1995
	Product availability	Divers type products, need based products, availability and storing facilities.	Schoenbachler & Gordon, 2002; Cox & Dale, 2001; da Silveira, 2003
Normative beliefs and motivation to comply	Trust	Trust on the online vendor, trust on delivery channel, having observability, trust on transaction medium, trust on online security and privacy.	Al-Ghaith et al., 2010; Siddiqui, 2008; Belkhamaz & Wafa, 2009; Palvia, 2009; Kim et al., 2008; Trocchia & Janda, 2003
	Perceived enjoyment	Degree of pleasure when using online shopping websites, Motivation for online shopping, attractiveness of e-commerce	Park & Kim, 2003; Venkatesh, 2000; To et al., 2007; Moon & Kim, 2001; Davis et. al., 1992; Cheng et al., 2006; Turle et al., 2007; Rouibah, 2008
Control belief and perceived facilitation	Prior experience	Familiarity with e-store website, Experience in using products from e-store, previous trust and service quality experience, overall experience of using online shopping.	Luhmann 2000; Gefen 2000; Hernández et al., 2010; Al-Ghaith et al., 2010; Rogers, 2003; Liaw& Huang, 2006
	E-commerce service quality	Service delivered through online service providers, Easy service features on website, quality for satisfaction and trust.	Flick (2009); Ha and Stoel, (2009); Molla, and Licker, (2001); Delone & Mclean, (2004); Parasuraman, (2002)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

adoption that might help explain features of e-commerce adoption in Saudi Arabia (Rogers, 2003; Al-Ghaith et al., 2010; Flick, 2009; Liaw & Huang, 2006).

Influential factors related to innovation diffusion and technology adoption were considered in this study across three broad dimensions, including the perceived characteristics of innovation; normative beliefs and motivation to comply; and control beliefs and perceived facilitation. Each of these broad areas contains sub-dimensions, which were defined and tested through the study hypotheses. The sub-dimensions and their use in this study are outlined in Table 1.

Hypotheses to specifically examine the interaction of these factors were developed. The hypotheses developed for this study were:

Hypothesis One: There will be a significant difference between e-commerce user groups (high volume, moderate and low usage) in terms of age.

Hypothesis Two: There will be a significant difference between online shopping user groups (high volume, moderate and low usage) in terms of gender (male and female).

Hypothesis Three: There will be a significant difference between e-commerce user groups (high volume, moderate and low usage) in terms of their ability to shop online.

Hypothesis Four: There is a direct and positive relationship between well-established e-commerce infrastructure and the level of users' online shopping adoption in Saudi Arabia.

Hypothesis Five: Inefficient financial systems and reduced payment safety have a significant direct and negative influence on the adoption of e-commerce.

Hypothesis Six: Poor delivery systems have a significant negative effect on the adoption of e-commerce.

Hypothesis Seven: Product availability has a significant positive effect on the adoption of e-commerce.

Hypothesis Eight: Trust in online shopping service providers has a significant direct and positive relationship with e-commerce adoption.

Hypothesis Nine: Enjoyment or a sense of pleasure has a significant direct and positive relationship with e-commerce adoption.

Hypothesis Ten: Prior experience has a significant direct and positive relationship with e-commerce adoption.

Hypothesis Eleven: Service quality has a significant direct and positive relationship with e-commerce adoption.

Hypothesis Twelve: There is a significant direct and positive relationship between delivery system and product availability.

Hypothesis Thirteen: There is a significant direct and positive relationship between trust and payment system.

Hypothesis Fourteen: There is a significant direct and positive relationship between prior experience of service quality and the use of e-commerce.

The model was developed based on the relationships of the hypotheses to be tested in order to shed light upon the factors that explain individual adoption of online shopping services in Saudi Arabia. The sub-dimension constructs outlined in Table 1 acted as the independent variables within the model. As such, they defined the level of acceptance of e-commerce in the form of online shopping uptake in Saudi Arabia. The sub-dimensions were defined and tested through the hypotheses, and the research model tested the interactions between individual sub-dimensions. With regard to the dependent variables in the model, a construct was developed to reveal the level of e-commerce adoption, which explores consum-

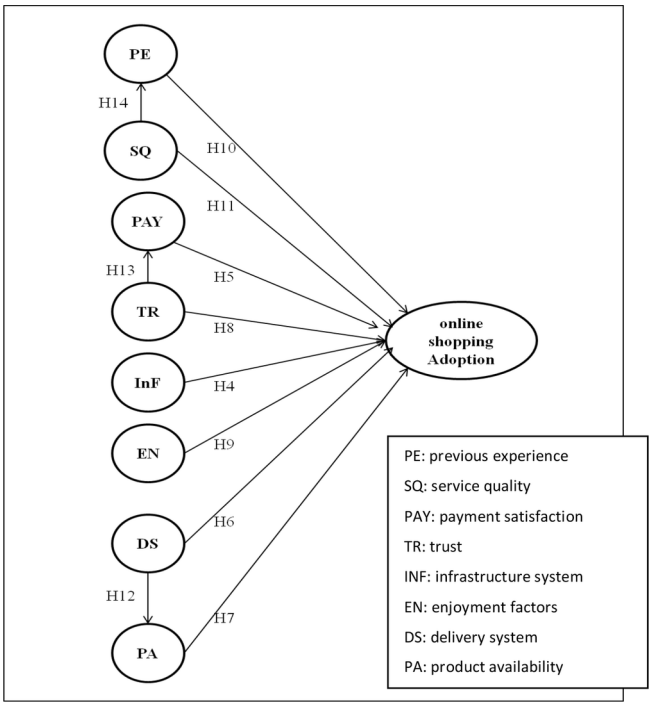
Figure 1. Hypothetical model of the factors influencing the adoption of e-commerce in Saudi Arabia



ers' intended approach, as well as their actual exhibited behaviour. Table 2 outlines the defining aspect of this construct, along with its sources.

The direct and indirect, as well as interrelated relationships of the independent and dependent variables provided a whole model that could be tested to answer the research hypotheses. The hypothetical model of the factors influencing the adoption of e-commerce in Saudi Arabia is illustrated in Figure 1.

Collection of Data

Survey Instrument

For hypothesis testing and developing the final model, a survey was conducted for data collection. For survey construction, an operational definition for the independent and dependent constructs in the proposed model was developed. Statements about each concept to be measured were based on those

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

refined during earlier investigations. To discover the participants' opinions regarding the study variables, the respondents were asked to indicate how strongly they agreed or disagreed with each statement. A 7-point rating scale was applied to the survey items, ranging from 1 (strongly disagree) to 7 (strongly agree) (Likert, 1932; Likert, 1974).

To validate the prepared survey, ten online shoppers possessing similar characteristics to the population in this study were surveyed face-to-face, including three PhD students, three professionals in e-stores and four regular online shoppers in Saudi Arabia. Additionally, five experts were consulted for the face validity, a professor, two lecturers and two statisticians. Based on their comments and feedback, some of the terminology and phrasing used for the constructs were modified to improve the clarity of the survey items and some modifications were made to the overall survey, optimising both its efficiency and validity.

Preliminary Assessment of the Proposed Conceptual Model: Exploratory Factor Analysis (EFA)

A pilot study was conducted for the preliminary assessment of the proposed conceptual model. The assessment was carried out in order to confirm the reliability of the items and the clarity of the statements in the survey. For the purpose, 100 surveys were distributed to online shoppers selected randomly from online stores whose managers provided customer email addresses. The response rate was 71%. The data collected from the pilot survey was examined for scale reliability, sampling adequacy and factorability utilising *SPSS* version 20.

To assess the scale reliability of the survey, an exploratory factor analysis (EFA) was performed. Despite the fact that all variables in the instruments were obtained from previous research and theories, EFA was essential to check whether these variables would operationalise and provide an appropriate scenario in the context of online shopping in Saudi Arabia. The justification for using factor analysis was based on the assumption that the data matrix had sufficient correlations among the variables (Hair et al., 2010).

In conducting an EFA, the selection of factor extraction and proper rotation methods for extracting the factors are always crucial (Tabachnick & Fidell, 2001). In this study, principal components analysis (PCA) was selected as the factor extraction method and varimax variation with Kaiser normalisation in *SPSS* v.20 was selected as the rotation method. Principal components analysis (PCA) was selected to produce initial solutions for the EFA. Each constituent interpretation looks for a decreasing quantity of total difference in the original variables, and processes what the variables have in common (Churchill & Iacobucci, 1987; Cooper & Schindler, 2001).

The examining orthogonal influence enquiry model with varimax variation was used as the rotation method because conclusions produced from orthogonal variation have a greater replicability and generalisability control when likened with leaning variation. There are three standards used to control the number of influences to be extracted: the dormant root condition (Eigen value); the proportion of difference criterion and the screen test standard. Eigen standards larger than 1 are important in the dormant root standard. It is common to employ a solution that accounts for 60% (or less) of the total variance in social science research, because the information in this field, by its nature, is often less accurate (Hair et al., 2010, Kaiser, 1960). In selecting the items, only items with a loading value over 0.4 were extracted as factor loadings. Below 0.4 are considered too low to be included (Field, 2013; Stevens, 2012).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Sampling

The eventual target population consisted of online shoppers in the Kingdom of Saudi Arabia. Studying the entire population of Saudi Arabia was not feasible; therefore, a sample of the population was selected to represent the Saudi population as a whole, with very high statistical accuracy and significance (Cooper et al., 2006). A sample size of at least 300 is generally regarded as reliable for factor analysis methods and statistical modelling (Tabachnick & Fidell, 2001). However, a sample size of 200-500 persons is considered sufficient for data analysis (Hair, 2010). For the research reported here, and using Cochran's formula, for a 95% confidence interval, a total of 384 participants was considered to be sufficient (Kotrlik & Higgins, 2001; Tabachnick & Fidell, 2001; Hair, 2010). In light of both factor and data analysis needs, it was therefore determined that responses from a minimum of 500 online shoppers would ensure the accuracy of the results.

Final Survey

After testing the survey and making amendments to the layout and ordering sequence of the items, the final survey was carried out in July 2013 and lasted for three months. In this study, the geographical distribution of samples was very large (covering major parts of Saudi Arabia). Therefore, a face-to-face survey or even a telephone survey was neither a time-efficient nor economical process. Considering this, the survey was conducted electronically, with all surveys delivered via an email link using an online survey tool, SurveyMonkey.

The online survey participants were selected randomly from online shoppers. An explanation of the study, along with a link to the survey on SurveyMonkey were mailed to the top 200 online customers of 15 online stores in Saudi Arabia. Materials were provided in both English and Arabic. From the 3000 emails sent, 1256 responses were received. After screening and processing the completed surveys, 904 surveys were found to have complete responses with no missing values or illogical responses. This sample was greater than the desired sample size of 500 respondents. All of them were used in the data analysis.

Data Analysis

Data Screening and Preparation

To prepare the raw data for final analysis, the raw data was visually checked initially, and then the completeness of the datasets was checked and legitimate responses were noted in order to identify the eligible respondents. In this case, responses without any variation were considered ineligible. After that, the managed data was entered into IBM-*SPSS* software (version 20) for further analysis.

Validity Testing

Reliability Test

In this study, the reliability coefficients were calculated using Cronbach's alpha to identify internal consistency based on the sample estimation. The literature suggests 0.7 as the accepted cut-off for a construct to be considered reliable (Hair et al., 2010; Santos, 1999).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Convergent and Discriminant Validity

Before entering the independent and dependent constructs into the model, the validity of these constructs needed to be checked. In this case, the validity check was performed only for the independent constructs. For this purpose, convergent and discriminant validity were calculated considering maximum shared variance (MSV), average variance extracted (AVE), and average shared variance (ASV). Convergent legitimacy shows how well the latent constructs are explained by the observed variables. For discriminant validity both MSV and ASV must be less than AVE. The threshold criteria for the validity tests are presented in Table 3.

In addition to these tests, square association amongst any two hypotheses was assessed through a factor correlation matrix with the square root of the AVE on the diagonal for the exogenous latent constructs. If any of the values are less than their particular AVE, then it indicates discriminant legitimacy of all concepts in the study model; that is, each hypothesis was dignified by particular objects that had no result on other hypotheses.

Table 3. Recommended measures for model validity

Analysis Test	Recommended Criteria
Convergent validity	AVE > 0.5
Discriminant validity	MSV < AVE ASV < AVE

Source: Hair et al., 2010

Factor Analysis: Confirmatory Factor Analysis (CFA)

Confirmatory factor analysis (CFA) was undertaken to confirm the feature arrangement of a set of experimental variables, and to guarantee that all the ideas in the model influenced convergent legitimacy, construct cogency, discriminant authority and factorial validity (Byrne, 2013; Hair et al., 2010). In summary, CFA is particularly a SEM function, which is used to validate hypothesised theoretical constructs (or factors). In this study, CFA was used to check the conformity of the factors that were identified in the EFA process. It was run before the SEM to make sure the SEM relationships were related to a specific model. Issues of reliability and validity of the observed and latent variables were also identified using CFA to ensure a better fit of the final SEM.

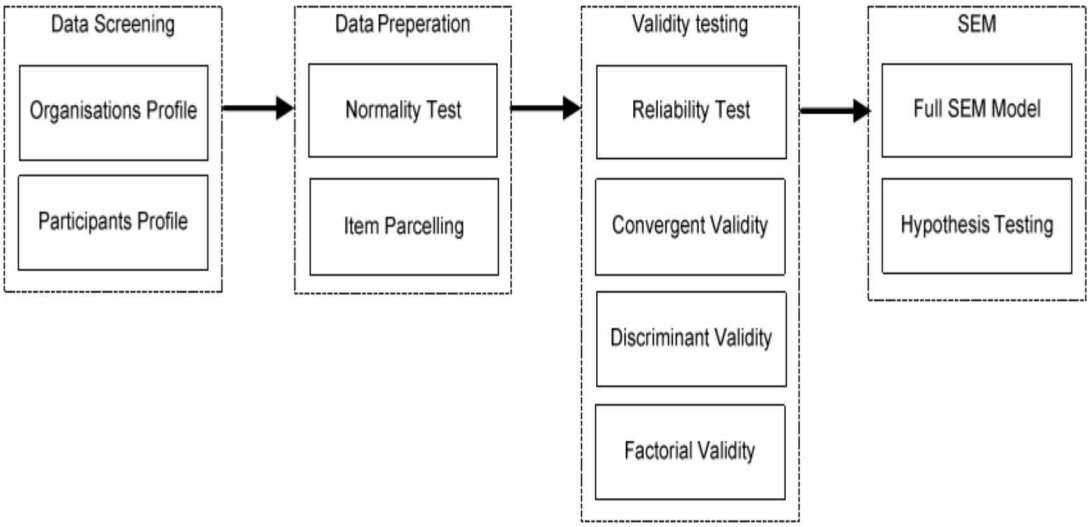
Structural Equation Modelling (SEM)

Structural equation modelling (SEM) was a major analytical technique used in this study to explore the complex relationships between e-commerce proficiency and the independent variables that determine the level of e-commerce use. Different steps of the modelling process are shown in Figure 2.

SEM was selected for this study because of its illuminating aptitude, its complete figures of model analysis, its general practice as a trial and error model that can be tested several times, and its capacity to progress stronger models by analysing philosophies on the quantified associations (Byrne, 2013; Hair et al., 2010; Rubio & Gillespie, 1995). This implies that with different tests, the strongest model would be accepted, and it would show the relationships with validity and reliability. SEM permits the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 2. SEM modelling process (Source: Al-Gahtani et al., 2007)



concurrent investigation of up to the 200 variables, permitting the inspection of widespread connections among arbitrator and latent forecaster variable pointers (Al-Gahtani et al., 2007). In the most common form, SEM looks for variation, co-variation, path, and the relationship between measured variables and latent variables (Suhr, 2006).

In this study, the hypothetical model (Figure 1) consisted of both observed and latent variables, alongside complex interrelationships among the variables that required SEM to find the ultimate empirical decisions. To investigate the hypothetical model relationships, SEM was applied among the factors extracted from the CFA analysis with proper validity and reliability. As part of SEM analysis, the path analysis was run and the coefficients and significance of the relationships were estimated using estimated path coefficients, t-values (critical ratio) and standard errors.

The path coefficient and the critical ratio reflect the strength of the relationships between the independent and the dependent constructs, and standard errors represent the number of errors in the path coefficient that are caused by the presence of a sampling error. The critical ratio (t-value) is obtained by dividing the path coefficient by the standard error, and this provides the basis for hypothesis testing. A hypothesised relationship is considered to be significant if the estimated critical ratio (t-value) exceeds a standard critical ratio of ± 1.96 (significant at alpha (α) level 0.05) or ± 2.56 (significant at alpha (α) level 0.01) (Gefen et al., 2000; Lind et al., 2005). Here, *AMOS* (version 19) was used to analyse the SEM model because it was developed by IBM to run as an extension program to *SPSS* allowing high confidence in the compatibility of results between *AMOS* and *SPSS* (Arbuckle, 2013; Blunch, 2013).

Goodness-of-Fit Test

Testing the model fit for both CFA and SEM is mandatory to ensure the model result is admissible and acceptable. The overall fit of the model determines the extent to which the overall hypothesised model is consistent with the collected data. The goodness-of-fit index (GFI) also explains the reality that can be expressed by the model. Following the recommendation of different researchers, some measures from

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 4. Goodness-of-fit indices and criteria used in this study

Assessment Index Category	Fit Index	Acceptable Level	References
Absolute fit index	Chi-square $\chi 2$ (p value for the model)	Insignificant p value ($p > 0.05$)	Gefen et al., 2000; Barrett, 2007; Hooper et. al., 2008; Hair et al, 2006
	CMIN/DF (normed Chi-square ($\chi 2$/df))	< 3 good; < 5 sometimes permissible	Hair et al, 2006; Tabachnick & Fidell, 2007
	RMSEA (root mean square error of approximation)	< 0.05 good 0.05 to 0.10 moderate > .10 bad	Hu & Bentler 1995; Hooper et. al., 2008; Fan & Sivo, 2007; Leelayouthayotin, 2004
	GFI (goodness-of-fit index)	> 0.90	Miles & Shevlin, 1998; Hooper et. al., 2008; Hair et al, 2006
	AGFI (adjusted goodness-of-fit index)	≥0.90 good > 0.80acceptable	Hair et al. 1998; Kelloway 1998; Chau 1997; Rai & Patnayakuni, 1996
Incremental fit indices	CFI (comparative fit index)	> 0.90 (acceptable) > 0.95 (more appropriate)	Hu & Bentler, 1999; Suhr, 2006; Mak 2001; Miles & Shevlin, 1998
Parsimonious fit indices	PRATIO (parsimony ratio) used for model adding more parameters	> = 0.5 closer to 1 better	Leelayouthayotin, 2004; Hair et al, 2006
	CAIC	$CAIC_{model} < CAIC_{saturated}$	Akaike 1987; Diamantopoulos & Siguaw, 2000; Hooper et. al., 2008

each type of index were used in model assessment (Joseph F Hair, Anderson, Tatham, & William, 1998). Three types of fit indices were selected for assessing model fit in this research, i.e. absolute fit indices, incremental fit indices, and parsimonious fit indices. Table 4 shows goodness-of-fit indices and criteria used in this study. In this study, *AMOS* (version 19) was used for the goodness-of-fit test.

RESULTS AND DISCUSSION

Preliminary Assessment of Proposed Conceptual Model: Exploratory Factor Analysis (EFA)

The results of the EFA are presented in Table 5. The results illustrate that the item loadings of 26 variables were significant and well above the 0.40 threshold without having any cross loadings among the eight extracted factors. In addition, the factor analysis explained 64.65% (cumulative percentage) of the variance criteria. These results indicate that the factor analysis provided reliable and valid extracted factors from the literature, as all the extracted factors had Eigen values greater than 1 and cumulatively the factors explained 64.65% of the variance, demonstrating consistency. The results confirmed that the developed instruments consisted of reliable and valid items, which sufficiently captured the meaning of the model constructs and their associated factors.

Validity of the Proposed Conceptual Model

Reliability and Convergent-Discriminant Validity

The Cronbach's alpha, MSV, AVE, and ASV are presented in Table 6. In this study, all the constructs showed acceptable reliability, as all have a Cronbach's alpha value over the threshold of 0.7. Thus, it was concluded that any of these constructs could provide acceptable reliability for the next stages of SEM analysis. Additionally, there was discriminant validity for all of the constructs, which indicated that none of the constructs of the model would have any effect on other constructs. However, there were

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Table 6. Reliability and convergent-discriminant validity analysis for independent constructs

Construct	No. of Items	Cronbach's Alpha	AVE	MSV	ASV
Product availability (PA)	2	0.759	0.606	0.071	0.017

two constructs (previous experience and enjoyment factor) that had convergent validity issues due to misinterpretation by the respondents. This was not a problem for the structural model, however, even though the convergent validity was not to the highest mark.

Table 7 shows that the square association amongst any two hypotheses was less than their particular AVE, which indicated the discriminant legitimacy of all concepts in the study model. Thus, all the validity and reliability checks confirmed that the constructs could be safely entered into the structural model analysis.

Confirmatory Factor Analysis (CFA) Model

From EFA, eight latent factors were entered into the CFA model. Figures 3 and 4 show the CFA models including exogenous latent constructs (independent variables), exogenous latent constructs (dependent variable) and the covariates of these constructs.

Based on these models, the estimated model fit values are presented in Table 8. The table shows that the model fit for the independent constructs was good and fell within the acceptable limits, except

for Chi-square. Again, for the CFA model, including the dependent construct and the factors associated with this construct, all the model fit indices were accepted, except for the CFI value. In this particular model, there was only one construct. Thus, the uncorrelated nature of the constructs (as the base of the CFI value calculation) was not confirmed.

Therefore, despite all the fit values being good and acceptable, this index exhibited a lack of fit. Furthermore, CFI is not operative if most of the associations between variables approach zero, as this means there is less co-variance to describe. Therefore, in this CFA model, an invalid fit index was noted. Thus, CFA models, including independent constructs, a dependent construct, and the covariates of these constructs were developed from the proposed conceptual model to ensure a better fit of the final SEM.

Structural Equation Model

Figure 5 presents the SEM outputs and is a graphic representation of the structural model with the results of the hypothesis testing. However, for better understanding, the results are also presented in Table 9. Out of eight independent constructs, five had a statistically significant relationship with the dependent construct. Previous experience, payment, trust, delivery system, and product availability had a significant influence on or relationship with e-commerce acceptability. However, service quality, infrastructure, and enjoyment had no significant relationship with the acceptability of e-commerce. In addition, some internal relationships were found to be significant, such as the relationship between the delivery system and payment system, trust and payment. The model as a whole can explain 37% of the variance for online shopping adoption in Saudi Arabia.

Table 10 shows the overall fit indices of the SEM model. The indices exhibited a good and acceptable fit, except for CFI. CFI was below the acceptable level by a very small margin. As a whole, all the fit indices indicated that the model provided authentic and reliable results. Therefore, the use of this model to test the research hypotheses was authenticated. Thus, the model provided the significant predictors of e-commerce adoption in Saudi Arabia.

DISCUSSION

After collection and analysis of the data, it was concluded that demographic and cultural factors significantly affect e-commerce use in Saudi Arabia. The high and low frequency users were mainly young-adults, while the moderate users were mostly middle aged, indicating that age is an important demographic variable influencing the adoption of e-commerce. A similar conclusion was drawn by Alkhunaizan and Love (2012), and Eid (2011).

Gender also influences the adoption and amount of use of e-commerce in Saudi Arabia. Females appear to be more attracted to shopping online than males in Saudi Arabia. It is highly likely that women are more motivated to shop online because they are somewhat restricted in terms of when and where they can shop by cultural mores. E-commerce provides an easy option for purchasing without going outside the home, which is a major cultural issue in Saudi Arabia. These findings are consistent with those of Al-Ghaith, Sanzogni, and Sandhu (2010), and Al-maghrabi and Dennis (2009).

Data analysis also indicated that the knowledge and capacity to engage in online activities varied among the user groups, and the high frequency users were more technologically skilled and confident than the moderate and low frequency users in Saudi Arabia. The result is consistent with Fuller, Vician, and Brown (2006).

The analysis also indicated that there was no significant interaction between the availability or quality of ICT infrastructure (in particular e-commerce infrastructure) and e-commerce adoption, possibly because the users had no in-depth ideas about what an efficient ICT infrastructure consists of. However, the lack of a trustworthy system of payment as part of the e-commerce business model did have a negative and significant impact on the adoption of e-commerce. Previous studies have also highlighted the fact that for online shopping in Saudi Arabia, the payment system lacks efficiency, as well as security, (e.g. credit card fraud, theft of financial details and hacking) (F. Aleid, Rogerson, & Fairweather, 2009; Rayed AlGhamdi et al., 2012; Rayed AlGhamdi, Nguyen, Nguyen, & Drew, 2011; Almousa, 2011).

In Saudi Arabia, the purchase delivery system has a negative effect on the adoption of e-commerce due to the poor postal service. Previous studies of Saudi Arabia also found that the purchase delivery system is one of the major obstacles to the expansion of e-commerce, as the delivery system is not even close to the standard followed in the developed world, and citizens who want to shop online face huge problems in getting products delivered after an online purchase (Aleid et al., 2009; Rayed AlGhamdi, Drew, & AlFaraj, 2011; Rayed AlGhamdi, Ann Nguyen, et al., 2011).

Product availability also discourages the adoption of e-services in Saudi Arabia because many products are banned from sale or restricted for religious and legal reasons. If these products were to be made available online (and unrestricted by government regulation), this would boost interest in e-commerce and provide online stores with a strong competitive advantage.

Trust is a positive factor that encourages the uptake of e-commerce in Saudi Arabia. International vendors, such as Amazon and eBay and other large e-commerce sites have been used by many users in Saudi Arabia, and have a positive image that has helped users have faith in online purchase and payment. In contrast, local e-stores have a somewhat negative image and faith in them is relatively low. To improve the image of trustworthiness for the local e-stores, Saudi Arabian e-stores have formalised an index site that lists the most reliable and trusted local online stores. These findings are in line with the findings of other researchers Rayed AlGhamdi et al. (2011) and Al-maghrabi and Dennis (2009).

Analysis of the research data showed that enjoyment was an insignificant factor for e-commerce adoption in Saudi Arabia. The explanation of this result might be found in the cultural context of the study.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

In Saudi Arabia, people mostly shop by visiting stores, while online shopping is often considered to be more necessary than fun, due to an absence of pleasant website images, animation, humour and lack of interactive features, as noted by Al-Ghaith et al. (2010). Many women enjoy the opportunity provided by shopping to gather with friends, and may not enjoy online shopping, which is generally a solitary activity. Furthermore, unemployed people with money provided by the head of the family or father like to go shopping in a physical location in order to fill their free time with some activity.

Companionship and the sights and sounds of the marketplace make real shopping more enjoyable than virtual shopping, always recognising, of course, that unemployed women in Saudi Arabia, who are the vast majority of the of women, face restrictions outside the home that moderate their feelings of enjoyment. These circumstances may explain why those engaging in online shopping did not emphasise enjoyment as a factor in their use of e-commerce systems. This result contrasts with previous studies by Lee, Cheung, and Chen (2005), Moon and Kim (2001), Turel, Serenko, and Bontis (2007), and Rouibah (2008), who found that enjoyment was an important predictor of e-commerce adoption. This contradiction may have occurred due the sample size variation and the personal views of the users.

In this research, prior experience was found to have a direct and positive relationship with e-commerce adoption. In Saudi Arabia, e-stores are trying to capture more customers, which has led to efforts to provide a better experience for customers, and engender positive feelings towards the adoption of e-commerce. This finding is consistent with a study by Al-Ghaith et al. (2010). For example, Saudi Arabian e-commerce vendors are trying to provide not just a better experience for their customers online, but are also offering post-purchase service for online customers.

Despite all these positive developments, however, users' attitudes toward local online vendors discouraged them from online shopping. The study respondents stated that products bought online were too often not as promised on the website. In addition, the details of the product were often poorly explained. All these negatives were intensified by a lack of communication with e-store managers, since very few e-stores in Saudi Arabia have call centre facilities. Thus, the respondents did not get the opportunity many times to judge the quality of the e-store vendors, as they simply assumed the worse regarding service quality based on earlier experiences. Thus, though service quality had no direct influence on online shopping adoption, there was a positive and significant interaction between service quality and prior experience. This result is in line with the result of Kassim and Asiah (2010).

There is a positive and significant relationship between the delivery system and product availability because product availability precedes product delivery. When users receive products on time and at low cost, it improves their perception of e-commerce, its convenience and reliability. This finding is in line with Ahn, Ryu, and Han (2005) and Schoenbachler and Gordon (2002). When users have faith in the probity of e-commerce vendors or an online payment or banking system, they are willing to provide their financial information to make online transactions. This result is confirmed by previous studies, such as Özgüven (2011), Meskaran, Ismail, and Shanmugam (2013), and Kim, Tao, Shin, and Kim (2010).

CONCLUSION

This paper described the development of a model of the factors influencing the adoption of e-commerce in Saudi Arabia through a study of online shoppers. Firstly, hypotheses were developed, and a conceptual model proposed for the adoption of e-commerce in Saudi Arabia based on a literature review. The conceptual model was a demand side model, which was developed using a mixed model method. The basic

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

concepts of the model were taken from several other models–TPB, DTPB, TAM and UTAUT–which have been developed and validated in Western nations. The statistical model encompassed the ideas of the perceived characteristics of innovation, normative beliefs and motivation to comply, and finally the control beliefs and perceived facilitation of the users in relation to online shopping.

In order to empirically verify the research hypotheses and model, primary research was conducted using a survey and semi-structured interviews with both e-commerce users and providers. In the model, constructs from three major dimensions–perceived characteristics of innovation, normative beliefs and motivation to comply, and control beliefs and perceived facilitation–were included. From these three dimensions, eight independent constructs–payment security and convenience, ICT infrastructure, delivery system, product availability, trust, enjoyment, prior experience, and service quality–were entered in the model. Using SEM techniques, the significant predictors among these eight constructs were identified.

The results of the data analysis confirmed that the constructs of the model explained 37% of the variance in e-commerce adoption (usage) for respondents in Saudi Arabia. Among eight independent constructs, five (previous experience, payment, trust, delivery system, and product availability) were found to have a significant relationship with the dependent construct (e-commerce acceptability). Three constructs (service quality, infrastructure, and enjoyment) were found to have no significant relationship with e-commerce adoption. In addition, some internal relationships were found to be significant, such as the relationship between the delivery system and payment system, trust and payment. On the whole, the model provided the significant predictors of e-commerce adoption in Saudi Arabia.

This model will potentially assist professionals interested in services supported by ICT, the wider business community, and the government to undertake comprehensive, effective, and sustainable solutions for the betterment of e-commerce in Saudi Arabia. Additionally, the methodology used in this study involving a mixed model that took basic concepts from several other models, and its development will guide other developing countries to form new models from already established models to highlight issues faced in their countries in relation to the adoption of national e-commerce.

This study only focused on current online shopping adopters. Data provided by non-adopters could have added greater depth to the understanding of why they are not using e-commerce facilities at all. Moreover, this research included only the variables related to the demand side (user side), limiting variables for the supply side (e-commerce vendors). So, future studies should consider non-adopters for identifying factors influencing the adoption of e-commerce in Saudi Arabia. In addition, interaction models (demand and supply) with more variables should be used. These would provide more dimensions of online shopping and retail e-commerce in Saudi Arabia.

Chapter 31
Designing Indulgent Interaction: Luxury Fashion, M-Commerce, and Übermensch

Christopher J. Parker
The University of Manchester, UK

Stephen A. Doyle
The University of Manchester, UK

ABSTRACT

Electronic Commerce (e-commerce) has transformed the retail environment and has become an ever increasingly important channel of the global economy. Within this, fashion retail has been a driving force, with increasing brand growth and profit deriving through Mobile Commerce (m-commerce). While the high-street fashion retailers have been key drivers and innovators in creating engaging and persuasive m-commerce app offerings, the high end and luxury fields have to date been slow to adopt and innovate at a comparable rate. This chapter explores the history and meaning of luxury and branding, in relation to the current state of m-commerce in fashion. Specific reference is given to the current state of m-commerce design in the retail domain between luxury and high-street market levels. Key questions and leading developments in the realm of interaction and User Experience (UX) design are presented along with directions on how to design for luxury m-commerce interactions.

INTRODUCTION

Design may be considered as a holistic field of study and practice on how to directly influence the lives and behaviours society, defined as *"a creative activity whose aim is to establish the multi-faceted qualities of objects, processes, services, and their systems in whole life cycle"* (International Council of Societies of Industrial Design, 2016). It is therefore interesting how the call for better realisation of the power of integrating design practice and mind sets into corporate entities has been on-going for more than 32 years (Kotler & Rath, 1984), yet has only recently began to be accepted and verified within the corporate environment (Borja de Mozota, 2003; Stickdorn & Schneider, 2010). While a full appraisal

of Design Thinking's impact on the business ecosystem lies outside the scope of this chapter, a central concept of this process is the designer's prior intention on how the product or service may be interacted with. Such complex interactions therefore must be approached with careful consideration of psychology, but also the realisation that a design is not a single creation, but an iterative process of creations building upon each other.

A core concept here then is the design of the interactions with the fashion mobile commerce (m-commerce) apps. One of the most fundamental concepts in interaction design is that of constant change and progress that in time comes to eclipse the past developments that in their day were heralded with greatness. Driven by the exponential increase in processing power (G. E. Moore, 1965) and internet bandwidth electronic commerce (e-commerce) has evolved from the rudimental sites of the early 90's to the highly complex, interactive, and seductive offerings of today's mobile commerce (m-commerce) platforms. To this, it may be tempting to look at the tailored retail focus of apps such as Mallzee's *"super personal"* fashion recommendations (C. Russell in Shaul, 2016), or the charismatic design of the Starbucks (2016) app as the pinnacle of what interactivity and style can provide. However, such a thought would be a close echo of Designer Philippe Starck's (2007) comments that humanity always looks at itself as the 'final man', a pinnacle of excellence in humanity not to be surpassed. However, such a perspective blinds us to development, change, and creating the next evolution. Instead, we should look at what is not great and seductive about current offerings, and reimagine new ways of interacting with our retailers to deliver not only increased functionality, but also exceptional service and emotional connections.

The concept of making certain behaviours within interactions feel emotionally rewarding (or seductive) has existed for many years (S. P. Anderson, 2011), and in a scientific realm, the theory of hedonic and utilitarian motivation for e/m-commerce purchase has been utilised widely (e.g. Parker & Wang, 2016). The question therefore is not *'what is seductive'* in interaction or *'how can interaction be made seductive'*, but instead *'why are fashion retail interactions so unexceptional'*. This of course requires qualification. E-commerce, while once mused on as a passing trend (Gilmartin, 2003) has seen tremendous growth of the last decade, with 12.3% of all UK retail (equalling £42.5 billion) in 2015 being handled through e-commerce platforms (Mintel, 2016). Particularly, fashion business is one of the most prominent sectors within e-commerce, with approximately 55% of UK residents having bought *"clothes or sporting goods"* online (Office for National Statistics, 2015); representative of 25% of all e-commerce revenue (Mintel, 2016). However, the fashion market represents diverse market levels, with each level performing to a different extent within the m-commerce and interactive field. Using a common nomenclature (Jackson & Shaw, 2009), the market can be broken down into four levels of:

1. Economy (e.g. Primark, George ASDA)
2. High Street
    a. Mass Market (e.g. H&M, New Look)
    b. Mid Level (e.g. Top Shop, M&S)
    c. High End (e.g. All Saints, Coast)
3. Diffusion (e.g. Marc by Marc Jacobs, Vivian Westwood Red Label)
4. Luxury (e.g. Dior, Marc Jacobs, Vivian Westwood)

An appraisal of m-commerce platforms by market level (Parker, 2016a) reveals that while many of the luxury designer brands have released an app (e.g. Gucci, Hugo Boss, Louis Vuitton) their apps rarely allow for the purchase of items or offer a limited and often introductory level range. Instead, they

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

mainly offer lookbooks, aspirational imagery, and news on the brand as a form brand experience. This is in contrast to the interactive transactional apps offered by the High Street retailers. Consequently, a schism appears within contemporary fashion apps between those primarily of hedonic experience, and those of utilitarian transaction.

The objective of this chapter is to present an in depth analysis to the ways luxury fashion retailers engage with their consumer base through e-commerce platforms. Through this, key questions on the design of fashion e-commerce are raised in line with the current state of interaction design in the m-commerce field. Finally, recommendations for the design of luxury e-commerce platforms for enhanced consumer experience are delivered. It is our intention that this chapter should deliver not only guidelines for exclusive content development, but a theoretical framework that retailers at any level can embrace and utilise in order to foster development and innovation within their marketing and design process.

BACKGROUND: DIGITAL MARKETING STRATEGIES FOR FASHION AND LUXURY BRANDS

Concepts of the Brand

Branding forms the strategic underpinning of most organisations, businesses, and public personalities, having evolved to become something that is to be built, maintained and arguably cherished (P. Doyle, 1990). Critically, brands are viewed as having significant influence with respect to consumers' purchasing decisions (e.g. Chovanová, Korshunov, & Babčanová, 2015) either through differentiation (Jane Roberts & Merrilees, 2007), relationship building, or by personal projection (Cătălin & Andreea, 2014). Importantly, brands provide longevity to the organization through the management of a set of assets and/or values (Aaker & Joachimsthaler, 2012). In this respect, brands are unifiers in that they have a defined characteristics and behaviours that shape and inform the business strategies. Subsequently, the consumer is able to connect or transfer these values to the product or service offered by the brand and make decisions based upon the extent to which brand is most closely aligned with their expectations and needs.

From the view of consumers, products are *what are bought* while brands *are what are bought into*. Brands therefore provide the long-term constant of decision-making while products can, and indeed must, flex in line with trends and fashions. In this respect, the brand is of greater importance than the product (Wong & Merrilees, 2008), although continued product failure or disappointment will inevitably tarnish the brand. The extent to which products will change is dependent upon the industry in which the brand competes. Within a fashion context, change occurs both across seasons and within seasons as a means of encouraging consumers to engage and purchase frequently. Conversely, in the automotive sector, changes are generally slower to emerge reflecting the level of investment required for product development and the frequency of purchase behaviours.

That stated, fashion brands (especially those operating in the luxury sector) must adhere to a set of guidelines that evolve into a handwriting that helps to define the brand and allow the customer to make decisions based upon familiarity. The brand in this respect has a necessary constancy (Nueno & Quelch, 1998) as well as a reputation and awareness (Michel Chevalier & Mazzalovo, 2008) about it that helps to simplify selection and decision-making. Fashion brands such as the Max Mara group have evolved a distinctive handwriting that allows the sub-brands to occupy specific, sometimes complementary positions in the marketplace. In line with Aaker's (2004) proposition, the Max Mara Group of brands reflect

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

the parent's attributes and values, especially in areas such as quality, but interpret and construct brands around them in distinctive ways in which to build loyalty, awareness, and positive associations across a range of customers and prospects.

Loyalty and the Brand

Inextricably linked with branding is long-termism (Okonkwo, 2007). In essence, a key purpose of the brand is to develop and sustain customer loyalty (Aaker, 1991); principally a manifestation of preference or attachment, although it may be borne out of different motivations. It results in a predisposition to purchase from one brand at the expense of another (Jacoby & Jacob, 1971; Phau & Prendergast, 2000). Okwonko (2007) suggested that it is a preference towards the company, the brand and the products and thus, loyalty is based upon an interlinked liking of past, present, and expected future satisfaction across those three aspects. Loyalty is therefore important to build future revenue (Jung & Sung, 2008). This is not simply a derivative of purchase continuation, but the associated reduced costs of servicing established customers.

In addition, loyal customers have the potential to become more expansive customers, whereby in a *quid pro quo* relationship, loyal customers need to be given a greater range of opportunities to purchase lest they become saturated and this in turns enables the brand to explore diversification and diffusion strategies (S. A. Doyle, 2002; S. A. Doyle & Reid, 2005; Liu, Li, Mizerski, & Soh, 2012). Hence, while loyal customers are therefore predisposed or biased, they also need to be given reason to engage.

Concepts of Fashion

In its broadest terms, fashion is about a shared, common, and simultaneous way of being, behaving or thinking within a definable and describable group (Tortora & Eubank, 2010). This concept of something shared is pivotal in shaping our understanding of fashion. This means that it has parameters, inclusions and exclusions; a time-based dimension which may be fluid but there needs be a beginning, a middle and an end. Fashion, therefore, has a temporal nature to it. Within the context of clothing, this transitory and transitionary aspect is effectively demonstrated by the product life-cycle curve cycle or the fashion adoption curve derived from Rogers (2003) proposition, whereby something may be described as 'fashionable' at the point when the majority of group members accept it and wear it. This is not to argue that the majority of a population will wear it, but that it has a significant level of adoption within a set.

This ebb and flow of products and more importantly styles, is at the heart of a fashion industry and is what defines it as distinctive from clothing. The fashion cycle recognises that there must be stages of introduction and of exit. For introduction the model argues that there will be innovators and early adopters who spearhead the movement, whether it goes beyond these initial stages will determine whether it becomes fashionable or not. In commercial terms, the majority is critical to achieve return on investment and thus fashion brands are required to select and interpret trends that they believe will be most appropriate to their customers and then to inform the customers of the availability and desirability of the product. In fast fashion the opportunity to so do may be brief (S. A. Doyle, Moore, & Morgan, 2006) and thus the opportunity to inform of and present an offer may have a greater degree of urgency than, for example, the premium and luxury sectors.

Companies and consumers are complicit in the need for change. Without it, clothing would be commoditised and consumption would be to satisfy the lowest level of Mazlow's (1943) hierarchy. While

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

there may be an environmental argument for this, the commercial argument has hitherto been weak. Nevertheless, what we see in recent years is an attempt by fashion brands to square the circle with respect to providing change and choice in a more sustainable manner (e.g. H&M Conscious, M&S Plan A). Such actions influence manufacturing decisions, product offers, pricing structures and message content whereby the how of fashion is increasingly relevant in shaping the story of fashion as presented to stakeholders include, consumers.

This in itself reflects a *fashion* in brand thought and behaviour, where a critical mass of companies, brands and consumers are now thinking about clothing in a different way. As suggested by the adoption curve, this way of thinking and behaving emerges with a small number of pioneering brands focusing their attention upon a specific group of motivated consumers (e.g. Slowear). This then becomes more progressively widespread. Digital platforms have undoubtedly helped press forward the shift through a swifter and more easily accessed communications system. It is now a rare fashion brand, at any level, that does not refer to social corporate responsibility.

Concepts of Luxury

Luxury as a concept is far from new. However, what is relatively new is the growth in luxury, both from a creation and consumption perspective (S. A. Doyle & Moore, 2015). Okwonko (2007) highlights that the current structure of the luxury industry was shaped in the 1970s, but suggests that the major changes have arisen from the 1990s onwards. Contributing to this shift, Okwonko (2007) suggest that shift from 'hand made' to the (semi)industrialisation of techniques, most obviously characterised in luxury apparel/fashion by the evolution of *pret-a-porter* from its origins in haute couture to its current meaning of *ready-to-wear*. It is of course important to note that although mass customisation may be offered as a service through interactive websites and apps (Parker, 2016c), the mail order fashion retail industry from early catalogues through to m-commerce can only exist due to the *pret-a-porter* garment production model given its need for a pre-established range of standardised products. This evolution may be attributed to a number of factors, mechanisation being only one of them. In addition, we may consider the limited growth opportunities offered companies reliant solely upon hand-made techniques and the associated volume strictures (S. A. Doyle & Reid, 2005) and a increase in both wealth and aspiration of the middle-classes (S. A. Doyle & Moore, 2015). There is a further dimension that may have contributed; the availability of post-war production facilities, materials and techniques as exemplified by companies such as B&B Italia (Matropietro & Gorla, 1986).

Okwonko (2007) brings to the fore the importance of luxury (fashion) as a means of demarcating and elevating the elite from the wider populace. Access to the most expensive materials and best craftspeople ensured that the position of the wealthy, an in the early history of luxury, ruling elite was enhanced, emphasised and expressed through demonstration; Veblen (1965) defined this as *conspicuous consumption.* Authority and control over labour provided the further means by which such classes could make manifest their wealth and power through personal adornment, but through the large-scale manipulation of their environments. Consider for example, the Pyramids of Giza (representing power in life and luxury in death), or Villa Adriana at Tivoli built as a country retreat for the emperor Hadrian. These structures, as do many more, share in common, access to and control of the means creating excellence and so, based upon these examples, we must also add to the list, access not only to craftspeople and materials but to thinkers, architects, etc. In its early phase, luxury and power go hand in hand.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

When considering luxury, it is important to address what it is, not least as this has clear consequences not only for what is offered but the manner in which it is offered. Kapferer (1997) argues that luxury is linked to the elevation of things beyond the merely functional. This is not to argue that luxury is not or cannot be functional; there is after all the expectation that a Rolls Royce will effectively travel from A to B. Instead, this highlights that luxury extends beyond the functional or that its function may be more complex than addressing base functions. Coco Chanel summed this up by stressing that "*luxury must be comfortable otherwise it is not luxury"* (Kuiper, 2010, p. 254).

Woodside and Ko (2013) placed emphasis upon luxury being linked to non-essentials in terms of product or experiences. This, as a definition, can be problematic, especially in a world often characterised by over-consumption and begs the question, what is essential? Critically, they temper this view by also suggesting that luxury is associated with rarity or expensiveness and thus there is the suggestion of exclusivity borne from non-availability to the majority through high price positioning, through a restricted volumes or a combination of both. Jackson (2004) similarly stresses exclusivity and expensiveness as characteristics associated with luxury goods. To these he adds high quality, distinctiveness and craftsmanship. Craftsmanship and high quality are echoed by Dubois and Duquesne (1993) along with heritage, history and culture. Reflecting upon these, Ricca and Robins (2012) in their analysis of luxury propose four pillars; craftsmanship, focus, history, and rarity.

Craftsmanship

Craftsmanship is key in the creation of luxury. This is often also a key dimension in the communication of luxury brands, and in particular, through digital media. Craftsmanship relates to a distinct and unique set of skills that separate luxury from mass manufacturing and often these skills represent a continuum with the brand's origins and history. Craft implies a level of intimacy, nurturing and care that is not associated with mass-market brands. Craftsmanship represents a benchmark according to Roberts and Armitage (2015). The notion of craftsmanship becomes a central dimension in shaping the perceived value of the luxury brand and its associated products, be that craft of making or craft of designing, and this reflects an expertise that has been honed and transferred over time.

Focus

Focus relates to the likelihood that luxury brands will operate within a relatively narrow portfolio of merchandise categories and products in order to best leverage their expertise (see craftsmanship). Luxury brands are best delivered and experienced when they avoid the over-extension of the brand thereby achieving excellence through constraint. This allows the brand to become recognised and respected in core categories. Focus enables the brand to optimise the limited resources available and to ensure that the brand adopts a long-term approach to decision making by staying 'true to purpose'.

This is not to suggest that luxury brands cannot evolve or diversify, but rather that such decisions are taken in recognition that the consequences of a wrong decision may be long-term. Added to this, investment levels are high, owing to material, skill and marketing costs and such investment can rarely be recouped in the short term. Too much change may suggest faddishness and while luxury may be fashionable, it is rarely associated with fad. With respect to extensive diversification, this is seem not within brands but within the portfolios of parent brands / conglomerates. Thus, organisations such as

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

LVMH, Richemont, and Kerring achieve an extended portfolio of offers and products across brands rather than within brands.

The importance of focus is demonstrated by British luxury fashion brand Burberry. In reporting the restructuring, the Financial Times (Oakley, Daneshkhu, & Vandevelde, 2016) highlighted the brand's desire to refocus its efforts on a reduced and simplified number of brands within its fashion portfolio. This would bring with it, reduced costs and reduced product replication. The most visible aspect of the restructuring is the consolidation of the brand under a single Burberry label, and the commensurate cessation of *Prorsum*[1], Brit, and London labels. Japanese-only derivatives *Burberry Black* and *Burberry Blue* were both withdrawn in 2015 as the brand pursued a more unified and singular approach with its fashion and beauty divisions. Interviewed by the Business of Fashion (Amed, 2015), CEO Christopher Bailey stated:

At Burberry we strive to deliver the purest articulation of out brand. This allows our customers to have a consistent and authentic experience…If you apply this strategy across the business as we have, it means operating on an in-house basis, to a large extent, allowing us to maintain focus and quality control across design, product development and ultimately, retail.

History

History implies heritage, durability, and longevity; characteristics widely played upon by luxury brands. History also implies security and given that for many consumers luxury is high involvement/ high investment, history provides a sense of continuity, consistency, and durability. History similarly has associations with success and such associations go hand in hand with luxury brands and luxury consumers. Luxury consumption is after all, most likely to be either the result of success or the communication thereof.

For luxury brands, history may be a source of trans-generational appeal if effectively managed, necessitating an evolutionary approach to development to ensure continuous flow of consumers. Failure to evolve may result in the brand becoming irrelevant and moribund and while it is possible to rejuvenate a 'dead' brand of the name and reputation carry sufficient weight and appeal; it is significantly more effective to sustain the brand. In this sense, it is about custodianship of the brand, managing it in a manner that builds new appeal to new generations.

Importantly, the fuller engagement with digital media provides a means by which to do this through channel relevance. Furthermore, digital provides the means by which luxury brands can communicate their history through storytelling and content in a way that delivers a potentially unbroken timeline without atrophying the brand. Madrid-based luxury brand *Loewe* uses digital to present narratives linking generations of users and within these narratives we can find not only the stories of the customer but the story of the brand (e.g. Loewe TV)

Rarity

The pillar of rarity aligns itself closely with that of exclusivity in that it reflects the limited availability of luxury and in so doing positions it clearly as distinctive from commodities. Rarity relates not only to the limited availability of the products of services, but of the inputs to those products and services. This, in part, 'explains' the price of luxury, but it also shapes its sense of not being everyday or commonplace. Rarity is also connected to focus and may reflect the concentration of materials, skill, and management

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

expertise required to deliver a luxury experience; or suggesting a technology being utilised so advanced that it could not be utilised or delivered on 'mass'.

Concepts of Luxury Fashion Brands

Within the broader discourse upon what luxury is and what luxury comprises, Fionda and Moore (2009) explore the specific dynamics of luxury within a fashion context and in so doing provide us with nine components. These, they argue should be evident and mutually supportive. In isolation, however, the building blocks of the luxury fashion brand, Fionda and Moore (2009) provide a template for luxury brand management, with each component extrapolated to reveal its sub-dimensions. As is to be expected, many of the components have their correlates in the more general literature on luxury. The nine components are as follows: *clear brand identity*, *marketing communications*, *product integrity*, *design signature*, *premium price*, *exclusivity*, *heritage*, *environment,* and *service and culture*. Within this model, we may also see what could be termed the '*permeable brand membrane'* through which the internal dimensions of the brand become externalised and thus within the consumer domain, be that by means of communication, physical environment, service experience or product (Tosti & Stotz, 2001).Within the realm of e-commerce design, it is imperative that these nine components are fully embodied within the experience of the app. Each facet of which represents a challenge for a designer to rise to during the design phase, and must form a key part of the app's sign off specification.

LUXURY FASHION IN THE M-COMMERCE DOMAIN

The Digital Landscape

Traditionally, brands relied upon physical retailing formats for the distribution of their products and this remains the priority mode of distribution in luxury (M. Chevalier & Gutsatz, 2012; S. A. Doyle & Moore, 2015; C. M. Moore, Doherty, & Doyle, 2010). Similarly, communication was dependent upon the traditional marketing approaches as delineated by Fionda and Moore (2009). Digital has however opened up a relatively new means of engaging with fashion and luxury consumers and this has created both challenges and opportunities.

While physical channels continue to predominate, there has emerged a set of fashion retailers for which digital is the single channel of commerce. Brand such as Yoox, Net-a-Porter, Mr Porter, and Boohoo.com have all adopted a digital business model. ASOS a pioneer of online, was launched in 2000 and has evolved into a global brand with coverage extending across 241 countries and territories (ASOS, 2016). In recognising the challenges facing any clothing retailer online, ASOS sought to offset these with quick and free delivery/ returns, detailed descriptions (including the models size data), true to colour photography, and highly innovative videos designed to represent the garment in motion and 3D. But while good examples may be found in the app domain, the way in which relevant and seductive interactive design is embodied within an app, website, or service is a concept of much greater depth.

First articulated by Kotler (1973) the concept and influence of retail atmospherics is now well established. While a full analysis of practice and the inter-relationship between environment and behaviour lies outside the scope of this chapter, an appraisal of over 60 empirical studies may be found within Turley and Milliman (2000), as well as Baker, Parasuraman, Grewal and Voss (2002). While taste, style, and

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

culture is an evolving concept to which store atmospherics must also change, there is a clear and distinct difference between the luxury retail environments and those of the high street and economy brands. The marketing company APS Group (2014) described the focus of high street retailers as being one of theatre, where when done right the act of shopping is transformed into an enjoyable experience. This can be read as an echo of the hedonic domain of Vivienne Westwood's World's End back in the 80's, with customers feeling *"like Alice walking into the shop - falling into Wonderland, where the clock span backwards and the flooring lay at odds to reality"* (J. Anderson, 2007). Even the foundational building materials of the stores can be considered, as Simon Wolfson (CEO of High Street fashion retailer Next) was quoted as saying that the brand is *"moving away from the traditional 'shed' to architectural buildings that reflect the design aspirations of our product ranges"* (Macdonald, 2014). These words can be seen in their underlying message as comparable to the description of Nottingham's flagship Paul Smith store, located in an 18th century townhouse with interior designed to match and compliment the designs and aspirations of the range (Experience Nottinghamshire, 2016). However, the atmospherics between high street and luxury makes little pretence of genuine overlap. Okonkwo (2007) described how Luxury retail differentiates itself from high street brands in the highly personalised service, focus, and attention delivered to customers, blended with at atmosphere that encapsulates the feelings of style and elites to which their customers emotionally associate with. While diffusion brands such a Zara seek to replicate visual and stylistic aspects of this, the model to which luxury fashion is sold is very different. While luxury fashion is sold at a premium, purposefully excluding non-customers and leveraging a budget to match derived from high profit margins, high street retailers move large volumes of garments fast and regularly, leveraging mass over low profit margins. Under these two retailing models, it would not be feasible for a high street brand to truly emulate that of the luxury retailer. Consequently, a form of atmospherics apartheid must exist not through design or will, but rather through emergence, where excellent service and experience may only be achieved through exclusion, exclusivity, and resulting budgets. However, outside the realm of the physical bricks and mortar stores, such limitations causing segregation of experience break down.

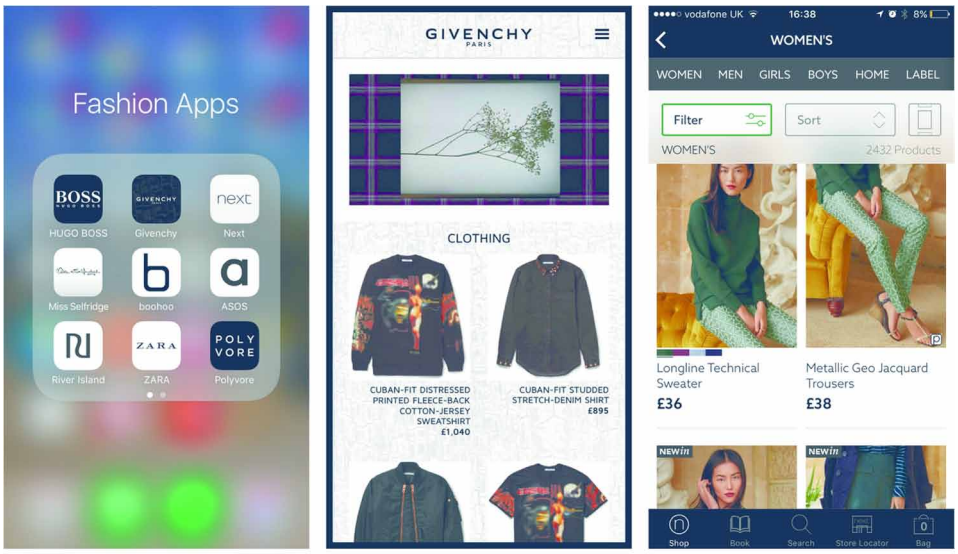
Since the creation of e-commerce in the 90's, one principle has sat comfortably in every text on web design: use a website to make you look bigger than you really are. This is one leveraged by the likes of Google, starting quite literally in their garage and rising to global dominance; helped by the veneer of professionalism that virtual sites offer which their humble beginnings could not. With their high profit margins, it is easy to understand how even a modest luxury brand may be able to produce a truly exceptional e-commerce experience. All that is required is a well-designed service, a manufacturing line to meet demand, a suitably talented web or app designer, and enough marketing spin to satisfy the elements of luxury fashion discussed in Concepts Of Luxury Fashion Brands section. While not all brands may be equal online, all brands may appear equally as professional, elegant, and luxurious with the right design and aesthetic.

Luxury and Fast Fashion Apps

While Forbes reported in 2016 that Dior remained the worlds largest fashion company (McGrath, 2016), Zara held the #3 position ($3.2B), and H&M came 6th with $2.3B. Therefore, despite differences in branding, product quality, and store atmospherics, all key players from luxury to economy retailers have far in excess the resources by which to deliver and maintain an e-commerce platform achieving excellence. Naturally, a minimum threshold for such excellence exists since design and photography are

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 1. iPhone App icons, Givenchy and Next iPhone Apps (Givency, 2016; Next, 2016)



not free. Yet with the ever increasing power of HTML 5 web applications (e.g. SquareSpace.com) and prosumer cameras and editing suits entering lower price points year upon year, even a startup business can develop a platform to rival the key players. This ability manifests itself in the great limitation in experience variety with e-commerce platforms between fast fashion, high street, and luxury retailers. Here, the retail domain is using the same 'design language' within their apps.

Focusing on two brands: Givenchy (Luxury) and Next (High Street), the differences in aesthetics and interaction are cosmetic and distinctive, yet neither one represents an advantage over; see Figure 1. Here, m-commerce breaks down the experiential differences and barriers that have existed within the physical realm. The reasons for the similarity in design are multiple:

One may think that in creating an e-commerce website the designer is free to develop any interaction they choose; this would be a false assumption. While we may think of modern websites to be simple, logical, and easy to use, overall this is primarily down to the designer recycling symbols, actions, and layouts to meet the learnt behaviours expected by a user. An example of this in our everyday life is how when visiting a bathroom in a restaurant, we will invariably enter the 'correct' room for our gender without given a second though. This is due to our instant and subconscious recognition of the symbology of gender placed on the door. However, when visiting foreign countries (particularly those of a very different culture) a visitor can feel confused due to the different use of gender identification symbols that they have not learnt (Gershenson & Penner, 2009). The same is true for interaction design, for example, the 'swipe down to refresh' interaction commonly seen in apps was not (unlike other features) mandated by Apple in their famous style guidelines (Apple, 2016), but rather a designed interaction (Brichter, 2010) that has been widely copied by developers world over. The interaction itself is not obvious, and no smartphone guide will instruct you, but it is functional, as it has entered the zeitgeist of learnt behaviours. The zeitgeist in such interactions is so strong that if a designer was to implement an alternative interaction (e.g. swipe right to refresh), users would find the experience difficult to discover,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

illogical, and ultimately the designer would be forced to drop their innovation in favour of more standard interactions (Preece, Rogers, & Sharpe, 2011). Through this, it is easy to understand why the fashion retail field produces apps and websites that appear uncannily equal to and on-par with competitors who are in no way within the same market sphere; e.g. Dior to H&M, Givenchy to Next.

This similarity in design goes more than skin deep. Naturally (excluding the influence of wealth and prosperity on a consumers' world outlook), the underlying psychology of shopping behaviour of those who can afford to indulge in luxury retail is the same as those who's only options are the economy brands. Consequently, it should be no surprise that in both physical and electronic commerce environments, consumers place greater emphasis on the utilitarian motivations over hedonic experience, yet still highly value the emotional experience derived from hedonic gratification (Parker & Wang, 2016; Resnick, Foster, & Woodall, 2014). However, differences in cognition do exist and play an important role in our app interactions. In a recent study within the University of Manchester, through 26 qualitative interviews with both high street and luxury fashion consumers, Kuo (2015) found that the higher the price tag of fashion merchandise the less likely they were to purchase through an app. By this, customers were happier purchasing low value items through the m-commerce platforms since the risk of the item not being as desired or expected was acceptable in order to attain the convenience the app provided. However, with more expensive purchases, the high price represented a sacrifice too great to risk, resulting a lower 'valued'; when considering a multidimensional perspective of value (Sweeney & Soutar, 2001). Therefore, the comfort and confidence that consumers feel when shopping for higher priced (i.e. luxury) items through m-commerce platforms is less than through cheaper (i.e. fast faction or high street items). The result is a lower willingness to purchase items that are still in every sense desired. This does not in any way indicate that luxury has no place within the m-commerce sphere, but it does demonstrate the need to design for luxury differently than we would design for high street or fast fashion brands.

Design for Luxury Fashion E-Commerce

Commonly, the most fundamental basis of app design is being user centred in your approach (design for the needs, desires, and actions of your users) (Norman, 2002), and iterating your product through user testing (Krug, 2009); seeking to iron out all issues over time. However, it is essential to remember that with all the user focus, co-design – in itself a highly creative methodology (Mitchell et al., 2015) – the design process is limited to the expectations and imagination of the subjects involved. Steve Jobs (BusinessWeek, 1998, p. 56) was famously quoted as saying that *"It's really hard to design products by focus groups. A lot of times, people don't know what they want until you show it to them"*. Jobs was not alone in observing such qualia in our knowledge of what shall provide us with exquisite experience. Pioneering Psychophysicist Howard Moskowitz once asserted that when simply asking consumers about what food tastes they most desire, that the mind does not know what the tongue desires (Gladwell, 2002). To this, Warnaby and Parker (2017) highlight how even the act of experiencing an environment as a tourist is fraught with an inability to 'know' what we desire. As a result, to meet the customer's expectations luxury brands, fashion e-commerce platforms cannot simply meet the consumer's verbalised expectations, but need to give a sense of wonder. Arthur C. Clarke (1962) famously wrote that any technology suitably advanced would appear as would magic to an uninformed observer. It is of course within the highest part of Maslow's (1943) pyramid where such hedonic experiences are necessitated and created. These are naturally coupling their association with the luxury fashion realm to concepts of wonder, akin to those found within the shops of Paul Smith and Vivienne Westwood, yet lacking through necessity

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

from Primark and H&M. This is an important element of the design process, and one that should be respected and followed in order to produce solid, enjoyable, and motivating retail apps. However, to not consider additional and alternative models of design as a luxury fashion app designer is to resign oneself to not achieving a great degree of 'magic', and operating within the same design sphere as the high street and entry level operators.

Doing so is not so much of a straight line as could be expected. Parker and Wang (2016) for example highlighted the importance of utility in fashion retail apps, of which being able to compare items to assess value and access savings is a key element; falling in line with price elements of multidimensional value (Sweeney & Soutar, 2001). However, Evanschitzky, Kenning and Vogel (2004) highlighted how the presence of 'value' and discounts may harm the exclusive price feel of a brand, and should thus be avoided. Therefore, an element of non-visual negative design may be required within luxury retail apps in order to foster the exclusivity and luxury status. While co-design and user centred design methodology has a strong history of producing excellent design for the masses, luxury brands should make design choices that may allow a high perception of value from those wealthy enough to not perceive poor *price value* elements as a sufficiently negative aspect. In effect, the apps 'design' characteristics need to embody negative aspects that subtly exclude the users who are not within their customer profile. This may be done through (for example) the decision not to include discounts, item comparison, or price filters.

The other aspect of increasing seduction within luxury fashion apps needs to be the adherence to trends. While fashion trends apply to every level of fashion retailing (Segre Reinach, 2005), the luxury market operates within a different sphere of trend interpretation. In a presentation on the future of luxury, Mattin (2016) discussed how the high street's increasing quality and ability to communicate trends to consumers has grown to the degree that luxury companies can no longer transfer their indulgent status simply by the consumer owning an expensive or rare item. Instead, such customers desire to be (as the authors of this chapter would term it) *übermensch*. This is not only to be highly on-trend with exquisite items, but also healthier, smarter, more creative, more emotive; the 'perfect' human rather than a human with 'perfect' products. While the luxury app may increase the multidimensional sacrifices required for engagement (fostering perceptions of exclusivity), providing intangible benefits in the form of promises that through engaging with the brand and their items the customer shall (subconsciously) become closer to the luxury übermensch, creating great benefits that increase the value of the app, the brand, and the items. This is supported by the findings of Kuo (2015) as well as O'Cass and Frost (2002) who found that luxury fashion customers utilise luxury items to identity and define their personal characteristics.

All brands from economy to luxury present images representing a 'perfect' lifestyle to which their customer base wishes to aspire to; purchasing items to (in some limited way) embody the imagery presented as an embodiment of the brand being *bought into*. However, the luxury brands position themselves as being a form of perfection above the so-called 'lower perfection' of high-street brands. While this concept may seem converse, luxury retail apps are already closely allied with lifestyle and emotive communication. As mentioned earlier how brands are brought into, we buy into lifestyle. The report by Parker (2016a) highlights how apps from luxury retailers almost universally include brand experiential elements alongside the m-commerce components. While Dior (for example) does not offer any m-commerce app, it does offer a Dior TV app, essentially a series of marketing videos that deliver the brand imagery to be bought imagery. The experiential elements go deeper here, with such offering such as Louise Vuitton's City Guide App, which offers a curated guide to leading 'fashionable' cities; in essence allowing customers to live the promised life of the brand, and in a small way fulfilling the desire of the übermensch. It is important however to note how high street retailers also achieve self improve-

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

ment aspects through guest blogs and fashion style guides by celebrities such as David Beckham within H&M's online magazine (Hennes & Mauritz AB, 2016).

This preference for experience focus over retail focus is not uncommon. This action also ties in with the findings of Kuo (2015) in that higher priced items for sale through m-commerce apps are less likely to be trusted. However, as multimillion dollar sales of items through eBay has shown, this trust barrier is not a hard one, and one that the Millennials and Generation Z members may not even recognise. However, high street brands Oasis, Mango, and Warehouse are already presenting experiential content within their m-commerce apps, so while a level of content differentiation exists at present, there is no barrier for high street or economy brands imitating their luxury competitors, and thus eroding the current intricacy high ground in the interactive domain. The question must therefore be asked, when design and content may be the same for luxury and high street retailers[2], how can luxury retail remain an aspiration and exclusive offering?

SOLUTIONS AND RECOMMENDATIONS

Returning to the concept of luxury brands delivering unattainable aspiration, and above all else, magic as part of their brand promise and to Arthur C. Clarke's (1962) concept of advanced technology appearing as magic, an opportunity arises for luxury brands to evolve their experiential elements by delivering highly advanced interactions driven by technology. While the sophistication and aesthetics of m-commerce has evolved since the Apple App Store opened in 2008, the underlying technical demands have barely altered. Focusing on heavy graphics processing alone as in Ray Ban's rather gimmicky Virtual Mirror (Parker, 2016b) is unlikely to produce a high quality and sophisticated interaction. Instead, as Steve Jobs (2010) championed, we should look to leveraging the technologies that are on the rise and lead the field, and not simply mirror existing practices.

Big data has already been harnessed within the tourism industry to allow travel brands to target individuals with specific offers and marketing that directly applies to them rather than general adverts for the masses (Kelly, 2013). A similar, practice is already in place within Facebook, allowing promoters to place their adverts in front of specific demographics on such granular details as their recent purchases, recent life events, excluding existing customers, appearing in front of customers who have 'liked' similar campaigns, and other personal demographics such as age, income, geo-location, etc. However, none of these currently offers any form of transitionary promise towards becoming übermensch. Nevertheless, with the ever-increasing volume of data being collected on our lives, the possibilities are endless. To this, in a near future where our homes are ubiquitously smart and connected, with every action of our work, social life, and even our bio-information and emotions[3] united through the Internet and smart items, data truly is the *Black Gold*.

It is beyond the scope of this chapter to propose the single solution of how to combine multiple sources of information and technology to produce magic. It is also possibly outside the scope of humanity to view such truly great innovations as our imagination is limited by our current understanding of the world. For example, in the first science fiction film A Trip To The Moon (Melies, 1902) the spaceship was completely powered by steam, gunpowder, and steam; reflecting the industrialised world director George Melies lived within. However, a framework of how to utilise such advancements for luxury m-commerce is possible.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Research by Mitchell et al. (2015) has demonstrated that individuals asked to come up with 'innovative solutions' to problems are significantly less likely to produce an innovative idea than a group of people working together within a design methodology framework. This should not be surprising since design as a discipline has over the last hundred years had a fascination with new ways of innovating and creating a future greater than the present world could conceive (e.g. see Bella & Hanington, 2012 for an excellent example of design methodology). Marketers should not simply rely on mimicking existing practices, but should utilise designers, and through effective design management (see Borja de Mozota, 2003) allow the designers to utilise a design thinking model in conjunction to the provision of emotionally connected services (see Stickdorn & Schneider, 2010). This can be characterised scoping the users' emotional needs (in luxury fashion related to the concept of übermensch embodiment), developing the underlying problem to be solved, ideating numerous innovative solutions, and finally delivering a design. Above all, letting designers be designers and innovating needs that consumers do not even know they have, and cannot clearly verbalise. This shall allow the luxury retailer to live up to the brand quality promise of delivering experiences beyond that of the high street. Coupled with suitably advanced technology, such a proposition of fulfilment shall deliver eloquent magic. Imagine the following scenario:

As you view adverts, lookbooks, and collections through the brands app, your smart watch and phone detects the subtle changes in your attention span and emotional response to the fashion stimuli. Your physical dimensions are captured through 3D body scanning, and triangulated with this, only garments that physically flatter your build and match your subconscious emotions are presented in your personal selection. The 'for you' feature goes further, by reading your calendar in conjunction to your social media activity and predicted weather, imagery, tone of wording, and physical properties of the garments (e.g. bikini or winter coat) are all considered to suggest exactly the right item for your upcoming celebration or holiday. When a friend's birthday is coming, their data are calculated to produce only gift suggestions that are guaranteed to make them feel emotions they would not be able to verbalise. The app may even analyse the quality of your social life, intellectual development, and relationship quality, and offer direct advice how to 'improve them' through selected partners; guaranteed to provide genuine self-improvement and emotional harmony.

While such hyper-personal services may seem far-fetched, they are within the clear reach of today's technology. Through the application of focused design innovation grander, more personal, and more emotional concepts can be developed. While good design and functionality may as highlighted earlier be universal, such developments shall require a great deal of skill, technology, research, and management; to the degree where only the most elite brands may be able to afford, drive, and develop them. This therefore represents an opportunity to re-establish the luxury brand as a truly exclusive and luxury service within a world where the traditional held values are loosing their exclusivity.

FUTURE RESEARCH AND DIRECTIONS

Behaviours, reactions, and even the underlying psychology of how the general population rationalises their model of the universe is a constantly evolving concept (Herrnstein & Murray, 1996). While academia has only recently begun to understand the differences between Generations X and Millennials (e.g. Giovannini, Xu, & Thomas, 2015), the retail scope is already marketing to and evolving for the

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

next generation; Generation Z. Just as we cannot assume that the cognition and preference of the Baby Boomers applies directly to the Millennials, we cannot assume that the current research and insights shall apply directly to the next wave of consumers. Future research must therefore keep re-questioning how and why consumers desire what they do in order to create greater and more intriguing offerings and services. While luxury faces a challenge today in how to distinguish itself, the question of how luxury brands can continue to evolve and present themselves with the brand image and interaction that they have held (to some degree) since the middle ages is yet unknown. However, the answer to this question shall not be one of aesthetics or taste, but instead a human factors design one, based on the emotions of excellence communicated through technology and service integration in a way that high street is unable to match.

CONCLUSION

Stability within the worlds of Fashion and Design can only be considered as an elusion of perspective, with each decade bringing new social and technological advances which shape business and consumer attitudes, forcing a change throughout our practices. This is a concept that is true in the earliest origins of artisan luxury brands of Medieval Europe, and it shall certainly be true in the world of future generations whose world shall be as alien to us as our Internet-connected world could be to our great-grandparents. Even if the essence of luxury fashion is kept the same (Chanel's iconic 'little tweed jacket' or the English cut suit for example) the way the brands present themselves and the ways that the consumer interaction needs to be designed shall always evolve. With that, it is imperative that the reader takes the essence of the history of luxury fashion and the principles of how their behaviours may be translated into interactive design, and develop their own interpretations, rules, and a third way to the mainstream. This chapter has presented a framework for which to design luxury fashion apps that far from simply delivering retail interactions, deliver the emotional elements of superiority and one becoming übermensch that luxury has, and always will require in order to exist and thrive.

KEY TERMS AND DEFINITIONS

E-Commerce: Electronic Commerce, retail through electronic communication channels (i.e., computers) delivered through the Internet.

Fashion: The sale and acquisition of garments and associated apparel for aesthetic more than functional purposes.

Haute Couture: Tailored and customised clothing from luxury/high-end fashion houses, distinct from 'standard' tailoring by the focus on perceived fashion status and trends.

M-Commerce: Mobile Commerce, a sub-branch of e-commerce, specifically the retail channels related to mobile devices (e.g. smartphones, tablets, watches).

Motivation: The desire for a person to engage in a specific activity, set of activities, or behaviours.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Pret-A-Porter: Clothes produced in bulk for a mass market to a set of pre-specified sizing categorise rather than through custom/ individual tailoring of a garment to fit a single individual. Alt name: ready-to-wear.

Übermensch: From the German of Super Man, conceived by Friedrich Nietzsche, relating to a person owning of 'superior' products and garments as well as embodying superior health, creativity, and emotional states. Not to be confused with the fascist concept of a superior race.

User-Centred Design: The design of products or services that is centred on the life and needs of the potential user base in its widest interpretation.

Value: The degree to which a person holds a product, service, interaction, or purchase to be greater, in that the benefits of accessing or acquiring it outweigh the sacrifices required in its acquisition.

ENDNOTES

1 Previously Burberry Prorsum

2 This extends to how high street brands directly copying the aesthetics of luxury brands, and even the practice of luxury designers producing high street or even economy ranges; e.g. Karl Lagerfeld (head designer of Chanel and Fendi) designing for H&M (Cope, 2016).

3. Wearable technology such as smart watches can already detect our movement, pulse rate, and soon blood sugar levels. Triangulated with GPS within smartphones and access to a contacts list, one could easily determine the emotion at a given location (e.g. Nold, 2006), or in relation to given persons or events.

Chapter 32
Electronic Commerce and Decision Support Systems: Theories and Applications

Kijpokin Kasemsap
Suan Sunandha Rajabhat University, Thailand

ABSTRACT

Electronic Commerce (e-commerce) is an advanced online business tool that allows many companies to launch their websites and helps customers search their specific products shown on the websites. Decision Support Systems (DSSs) are computerized tools designed to facilitate strategic decision making. With the support of data mining and business intelligence methods, DSSs can effectively increase the performance of decision making and can present a sophisticated method of managerial thinking in a timely and effective manner toward gaining competitive advantage. The chapter argues that utilizing e-commerce and DSSs has the potential to enhance business performance and reach strategic goals in modern business.

INTRODUCTION

Electronic commerce (e-commerce) is the online business with the support of computers (Kasemsap, 2015a) and becomes one of the required ways of online shopping (Kasemsap, 2018a). E-commerce creates a paradigm shift in the way modern companies conduct business (Kuah & Wang, 2017), and can help enhance the digital economy (Kamel, 2010). E-commerce has a tangible impact on the way business is conducted (Strzębicki, 2015). E-commerce tools has been made available that are able to help customers by generating purposed recommendations (Palopoli, Rosaci, & Sarné, 2016).

The emergence of e-commerce has provided manufactures and vendors with more business opportunities (Acampora, Alghazzawi, Hagras, & Vitiello, 2016). Electronic retailers may enjoy early mover advantages because of the consumer demand inertia amplified by the nature of the Internet and the system design characteristics of e-commerce platforms (Wang, Cavusoglu, & Deng, 2016). E-commerce websites increasingly incorporate tracking technologies that can monitor consumer behavior on their

websites (Currim, Mintz, & Siddarth, 2015). Evaluating usability issues allows improving the design of e-commerce websites (Díaz, Rusu, & Collazos, 2017).

Decision support systems (DSSs) are the computer systems designed to provide the assistance in evaluating alternative courses of action (Kasemsap, 2017a) and in enhancing decision-making processes (Kalina & Zvárová, 2013). Decision making is the cognitive process resulting in the selection of a course of action among several alternative scenarios (Kasemsap, 2016a) for solving complicated problems where multi-criteria objectives are involved (Tran, Abraham, & Jain, 2008). There is a growing trend to provide managers with information systems that can assist them in their decision-making processes (Averweg, 2010).

Because of the importance to individual, group, and organizational success (Forgionne, 2005), information systems research continues to examine the effective ways to improve the support for decision making (Forgionne, 2009). DSSs are a subset of information systems that support human decision making through computerized systems that offer contextual information (Bihl, Young II, & Weckman, 2014). The field of DSS development is reaching the end of its expansion stage, which is characterized by the proliferation of processes and methodologies in all areas of decision support (Gachet & Sprague, 2010).

The chapter is based on a literature review of e-commerce and DSSs. The extensive literature review provides a contribution to practitioners and researchers by indicating the theories and applications of e-commerce and DSSs in the digital age.

BACKGROUND

E-commerce represents one of the most promising directions for generating competitive advantage at the micro level of the organization and for increasing productivity at the macro level of the economy (Rahman & Raisinghani, 2000). Many companies have recognized the importance of developing an online platform with the objective of having a higher interaction with the client, and influence them in e-commerce, through the buying process (Ibarra, Partida, & Aguilar, 2015).

E-commerce has substantial potential to promote the growth of small and medium-sized enterprises (SMEs) in developed and developing countries (Kurnia, Choudrie, Mahbubur, & Alzougool, 2015). Due to the growth of e-commerce, more organizational resources are being directed into electronic securities, Internet facilities, business plans, and new technologies (Kasemsap, 2016b). E-commerce transforms the world into an information society (Kartiwi & MacGregor, 2008), and assists organizations in reducing the cost of entry and in expanding the market reach for a wide variety of business activities (Lin, Jalleh, & Huang, 2016).

Decisions are activities that individuals face and deal with every day (Abdou, Radaideh, & Lewis, 2010). The successes over the past 10 years in developing, implementing, and sustaining effective DSSs for decision making for both governments and businesses hold many beneficial lessons for the implementation of sophisticated systems under conditions of extreme difficulty (Kamel, 2006). Decision making is a crucial element of a manager's responsibility (Garrido, 2015) in both day-to-day operations and strategic planning (Abdelsalam, Dawoud, & ElKadi, 2013). Supporting decision taking by management in an integrated way means to support the global decision process of the organization and increase its efficiency and resilience (Garrido, 2015).

In recent years, DSSs have moved from a radical movement that changed the way information system was perceived in business, to a commercial information technology (IT) movement that all organizations

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

engage (Wang & Radosevich, 2010). Nowadays, many DSSs are based on spatially distributed sensors (Dunkel, Bruns, & Pawlowski, 2010). Organizations continuously need to increase their business intelligence by monitoring systems that analyze information and develop significant indicators to decision makers toward handling both semi-structured and un-structured problems characterized by varying parameters in order to understand the problem and to help develop alternative solutions (Kamel & Zyada, 2005).

ASPECTS OF ELECTRONIC COMMERCE AND DECISION SUPPORT SYSTEMS

This section provides the overview of e-commerce; trust and privacy issues in e-commerce; e-commerce and logistics; the applications of e-commerce; the overview of DSSs; knowledge-based decision support systems (KBDSSs); DSSs, data mining, and business intelligence; and the importance of DSSs.

Overview of Electronic Commerce

E-commerce describes the process of buying, selling, transferring, or exchanging products, services, or information via computer networks including the Internet (Toland & Klepper, 2009). Through e-commerce, organizations can easily evaluate sales effectiveness, customer effectiveness, marketing campaigns, product mix, and customer engagement in global marketplace (Kasemsap, 2016c), and consumers can purchase the cheaper and better products via price comparison (Yıldız & Kurtuldu, 2014). E-commerce optimizes and enhances the relationship and communications among companies, producers, distributors, and customers (Choshin & Ghaffari, 2017).

An important driving force has been the parallel rise of social media, enabling pervasive interactions among consumers and between consumers and firms (Lee & Phang, 2015). The influence of user-generated content (UGC) on e-commerce websites and social media has been addressed in both practical and theoretical fields (Yan et al., 2016). E-commerce and research and development (R&D) have a positive impact on gross domestic product (GDP) per capita based on the purchasing power parity, with e-commerce having a stronger development-enhancing effect in comparison to R&D (Anvari & Norouzi, 2016).

Given the tremendous success of the Internet and e-commerce in developed countries, emerging economies are quickly embracing IT as well (Agarwal & Wu, 2015). The Internet has provided great convenience for online shoppers, and has presented unprecedented opportunities for online retailers to understand their customers (Wu, Li, & Xu, 2014). In the wake of the rapid emergence of e-commerce, its evaluation is of great theoretical and practical importance (Kang, Jang, & Park, 2016). It is important for policymakers to consider both Internet application and e-commerce as the social and technical perspectives (Papazafeiropoulou & Pouloudi, 2003).

The implications of e-commerce include the facilitation of trade transactions and the acceleration of capital movement through the new rules of the digital economy with the removal of time and distance barriers (Kamel & Ghoneim, 2004). However, the global enterprises face the challenges of e-commerce, such as adjusting to competition in electronic markets, addressing privacy issues, and applying strategic management to corporate alliance systems (Raisinghani, 2000). Buyer concern about website security is a critical issue when it comes to maximizing the potential for e-commerce transactions (Hartono, Holsapple, Kim, Na, & Simpson, 2014).

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Multi-attribute value theory (MAVT)-based recommender systems are recognized for dealing with various issues of recommender systems, such as the cold-start problem and changing preferences (Scholz, Dorner, Schryen, & Benlian, 2017). Recommender systems are utilized by consumers who are not familiar with the available attributes and ranges and who wish to save time and effort. MAVT-based recommender systems can enhance consumers' decision processes in e-commerce shopping tasks.

Trust and Privacy Issues in Electronic Commerce

With the explosive growth of e-commerce worldwide, there are the growing concerns about fraudulent transaction attacks in e-commerce (Zhao et al., 2016). Consumers are concerned about the protection of their personal information and feel that privacy policies are important (Henderson, Snyder, & Byrd, 2003). In e-commerce environments, the reputation of sellers is a crucial issue to potential buyers in making decisions (Zhang, Wang, & Zhang, 2014). The inability to physically interact with an item, fear of risk security and privacy and lack of e-commerce infrastructure are the main barriers that prevent the consumers from online product shopping (Singh, Yadav, & Sahu, 2016).

A comprehensive conceptualization of trust in business-to-business (B2B) e-commerce should include trust in the infrastructure and the control mechanisms (Pavlou & Ratnasingam, 2003). Because mutual trust between buyers and sellers can enhance smoothness in communication and can increase buyers' confidence in online shopping, buyers are more willing to enjoy their transaction experiences with sellers (Huang, Chen, Ou, Davison, & Hua, 2017). Online exchanges often occur between strangers who cannot rely on past behavior or the prospect of future interactions to establish mutual trust (Bahbouhi & Moussa, 2017).

Online shopping as an alternative to in-store shopping can make much of traditional retail less attractive (Zhang, Zhu, & Ye, 2016). Ease of use has significant impact on usefulness, and trust has a significant impact on both ease of use and usefulness concerning online shopping (McCloskey, 2008). Consumer characteristics, company perspectives, website infrastructure, and interactions with consumers can affect the trust in e-commerce (Oliveira, Alhinho, Rita, & Dhillon, 2017). In addition, perception of website quality (PWSQ) and third party recognition (TPR) can influence the trust in e-commerce (Yoon & Occeña, 2015).

The rise of e-commerce forces IT personnel to move beyond infrastructure design and maintenance and consider numerous customer-facing aspects such as consumer data privacy and security. When developing IT systems and applications to accommodate e-commerce activities, data governance related regulatory compliance mandates, personally identifiable information privacy rules, and information protection protocols must be considered. To ensure the security, privacy, and effectiveness of e-commerce, businesses should authenticate business transactions, control access to resources (e.g., web pages for registered or selected users), encrypt communications, and implement security technologies

Electronic Commerce and Logistics

With large number of enterprises executing e-commerce (Masmoudi, Benaissa, & Chabchoub, 2014), logistics has been largely influenced (Yu, Wang, Zhong, & Huang, 2016). The goal of collaborative execution in global supply chain is to establish the smooth flow of information up the supply chain from customers to suppliers and the smooth flow of products and services down the supply chain from suppliers to customers (Kasemsap, 2016d). There are many retail and logistics companies utilizing e-commerce

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

as the important business tool, such as Home Depot (U.S.), Amazon (U.S.), IKEA (Sweden), JingDong (China), and GuoMei (China). Carriers and logistics intermediary perform more roles than what people think they do, because network connection and the ambition to remain competitive make them to take up value-added services (Kasemsap, 2017b).

Home Depot is an American retailer company that sells home improvement products and construction products. In the traditional model, each retailer store of Home Depot has a logistics management department, and this department is in charge of the store's replenishment, storage management, in/out products flow control, and other related issues. When suppliers receive the stores' replenishment orders, they have two ways to deliver orders to retailers, of which one is directly sending products to the store, the other is using Home Depot's distribution center to ensure cost-effective transportation.

For the Line-Haul phase, the Home Depot sets the centralized inventory and replenishment (I&R) department in the headquarters, and develops a new network of distribution centers for store replenishment. The new I&R department of Home Depot takes place of the individual stores' replenishment teams, and is responsible for all the stores' inventory management. Regarding e-commerce logistics, the centralized replenishment of Home Depot improves the demand forecast accuracy and gains more power for Home Depot while negotiating with suppliers as the single order is much larger than before (Yu et al., 2016).

Amazon is an e-commerce and cloud computing company (Yu et al., 2016). It is the biggest Internet retailer in the U.S. It began as an online bookstore, but its current business scope covers DVD, blue ray, CD, video game, electronic, furniture, food, toys, and jewelry. Amazon has independent sales website facing different countries across the globe. Amazon saves a lot of storage costs by integrating the inventories in distribution center and the warehouses of partners. Thus, there is no need for Amazon to keep a high level of inventory as physical retail stores. The determinants for locating distribution centers consist of distance from customer-intensive places and level of taxes.

Within the distribution center, Amazon has different processing procedure and equipment while dealing with various product groups. Those products, which are easily classified and transported, are stored in highly automated equipment, whereas those irregularly shaped products are handled by the equipment of low-level automation. While dealing with intercity transportation, Amazon sets many injection points, such as transportation hubs. Transportation hubs are located in the districts where customers are highly concentrated to save cost. Orders are integrated in the distribution centers first. After that, the less than truckload (LTL) shippers or truckload shippers will supply the long-haul shipment service, carrying them from distribution centers to the injection points (Yu et al., 2016).

Applications of Electronic Commerce

E-commerce typically utilizes electronic communications technology of the World Wide Web, at some point in the transaction's life cycle, although e-commerce frequently depends on computer technologies other than the World Wide Web, such as databases, and e-mail, and on other non-computer technologies, such as transportation for physical products sold via e-commerce (Drougas, 2009). It will be very useful for customers if e-commerce is capable of being more automated and secure than is the case, since the time and energy they spend will be reduced (Yi, Siew, & Syed, 2000). For small transaction sizes, invoices are the most cost-efficient payment method, while prepayments dominate for large transaction sizes (Grüschow, Kemper, & Brettel, 2016).

In the business environment, e-commerce has made considerable business development in modern business (Kartiwi & MacGregor, 2008). In societies where commercial competition is accepted as an

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

economic system, there is a positive relationship between the good operation of the system and the power of SMEs within the system (Zerenler & Gözlü, 2012). B2B e-commerce adoption enables SMEs to gain and sustain competitive advantage in a dynamic competitive environment (Hamad, Elbeltagi, Jones, & El-Gohary, 2015). Getting the pricing right has emerged as one of the most important keys to the success of e-commerce (Wu et al., 2014).

When problems occur in B2C e-commerce transactions, consumers require and expect an immediate redress procedure from merchants (Ong & Teh, 2016). Redress is concerned with internal complaint-handling procedures through which consumers seek compensation or to rectify the problems that occur during e-commerce transactions. Redress serves as an important determinant of consumer confidence and trust in e-commerce (Ong & Teh, 2016).

Overview of Decision Support Systems

Nowadays, information is a crucial element of an economic development of a society (Sobieska-Karpinska & Hernes, 2010). The important attributes of information are its urgency and actuality because a correct decision may be only made when the system is able to get the up-to-date information, which is needed to effectively make this decision (Sobieska-Karpinska & Hernes, 2010). The process of decision making in any organization is the resource-consuming system (Baruti, 2016). The manual and mechanical methods are associated with heavy cost of processing, low efficiency, inconsistency, lack of integrity, and long period of time in its processing so that institutions incur heavy bills in their decision-making processes (Baruti, 2016). DSSs in the domain of Industrial Engineering and Management can be the powerful tools, but more knowledge about the way users utilize these systems is required (Yuviler-Gavish & Naseraldin, 2016).

Traditional DSSs provide strong data management, modeling, and visualization capabilities for the decision maker but they do not explicitly support scenario management (Ahmed & Sundaram, 2010). The intelligent systems have extended the scope of traditional DSSs to assist users with real-time decision making, multiple information flows, dynamic data, information overload, time-pressured decisions, inaccurate data, difficult-to-access data, distributed decision making, and highly uncertain decision environments (Phillips-Wren, 2010). Regarding business perspectives, consumer decision support systems (CDSSs) help online users make effective purchasing decisions in e-commerce websites (Zhang & Pu, 2010).

Many businesses have made or are making significant investments in data warehouses that promote a myriad of DSSs (Wells & Hess, 2008). DSSs consist of three parts: database, model base, and user interface (Eom & Lee, 1990). Database involves the input data used in decision making. Model base includes many analytic or simulation models that utilize input data in order to produce strategic methods. The decision maker often interacts with data and models through the user interface (Tynjala, 2012). In addition, the factors of compliance, complementarity, and conformity can measure the performance of DSSs (Lebraty & Godé, 2015).

Knowledge-Based Decision Support Systems

Knowledge-based decision support systems (KBDSSs) are the systems designed to ensure more precise decision making by using appropriate data, information, and knowledge management (Chung, Boutaba, & Hariri, 2016). KBDSSs refer to decision making based on relevant knowledge, which is based on artificial intelligence, and on the application of information and communication technology (Chung et

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

al., 2016). Artificial intelligence is the area of computer science that emphasizes the creation of intelligent machines that work and react like humans (Kasemsap, 2017c).

Based on the knowledge used for deduction, data is classified into knowledge-based systems using dictionary-defined knowledge, and non-knowledge–based systems using machine learning and multidimensional statistical pattern recognition techniques (Kim & Ryu, 2013). Park and Han (2016) presented efficient decision support for detecting content polluters on social networks with an approach based on automatic knowledge acquisition from behavioral patterns. This study is an efficient method for detecting content polluters on Twitter. Park and Han (2016) proposed a set of KBDSSs-related features that can be easily extracted from the messages and behaviors of Twitter users, and established a new breed of classifiers based on these features.

Decision Support Systems, Data Mining, and Business Intelligence

Data mining and business intelligence techniques can be integrated in order to develop more advanced DSSs (Domingues, Jorge, Soares, & Rezende, 2015). Data mining is the process of applying the computational methods in showing unknown data formats in large data sets (Kasemsap, 2015b). Data mining is profitably utilized to discover patterns and relationships in the data in order to help make better business decisions (Kasemsap, 2016e).

Business intelligence is an emerging technology that helps executives and managers manage information and data in an efficient way (Kasemsap, 2015c). Business intelligence involves creating any type of data visualization that provides the insight into a business for the purpose of making a decision or taking an action (Kasemsap, 2016f). Business intelligence provides the quick notification of business exceptions, advanced reporting, and the ability to compare data to improve the strategic management in global business (Kasemsap, 2017d).

Importance of Decision Support Systems

Effective decision making across organizations is of strategic importance as the global business environment becomes more complex (Setzekorn, Sugumaran, & Patnayakuni, 2004). DSSs can enhance various operations, financial management, and strategic decision making (Wang & Yao, 2010). DSSs include allowing and motivating participation in decision-making conversations of individuals who may contribute to decision-making processes and to the quality of their positive outcomes (Garrido, 2011). DSSs need to be designed and developed with extra functionality to meet the challenges, such as collaborative working (Liu, Duffy, Whitfield, Boyle, & McKenna, 2009).

DSSs can be considered as the integrated entities that provide individuals with both tools and information to assist their decision making (Sharma & Vyas, 2010). DSS research is often blended with many expansions experienced by various information system fields, such as organizational computing, e-commerce, and pervasive computing (Burstein & Holsapple, 2008). DSS development methodologies must be described at a meta-level (El-Gayar, Deokar, & Tao, 2011). Thus, maturity models (MM) can provide the necessary framework and benchmarks needed to evaluate DSS development methodologies (El-Gayar et al., 2011).

Regarding DSSs, many decision makers begin to seek cooperators on the Internet to help them solve complex decision problems (Xie & Wang, 2014). The data must be obtainable, preferably via common protocols shared with the operational infrastructure (Tolk, 2010). The benefits of agent technology are

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

highlighted in relation to the desired features of DSS (Vahidov, 2004). Intelligent agents regarding agent technology have a high degree of self-determination capabilities, and they can decide for themselves when, where, and under what condition their decision-making action should be performed (Adla, 2013).

To achieve the effective DSSs, intelligent agents and automated forces must produce adequate behavior. If these requirements for simulation systems and their annotations are fulfilled, decision support simulation can significantly contribute to the situational awareness up to the cognitive levels of the decision makers (Tolk, 2010). Thus, DSSs can enhance human cognitive deficiencies by integrating various sources of information, providing intelligent access to relevant knowledge, and facilitating the process of making suitable decisions (Sodiya, Akinwale, Okeleye, & Emmanuel, 2012). Service efficiency, improved effectiveness, and increased stakeholder value are the expected benefits of DSSs exploitation (Ngwenya, 2013). Awareness of organizational resources-related online presence and availability can affect the decision-making process in pervasive computing environments (Russell & Forgionne, 2009).

FUTURE RESEARCH DIRECTIONS

The classification of the extensive literature in the domains of e-commerce and DSSs will provide the potential opportunities for future research. Social media marketing programs usually center on efforts to create the content that attracts attention and encourages readers to share it across their social networks toward competition in the global marketplace (Kasemsap, 2016g). The Internet of Things (IoT) relates to the utilization of advanced sensors, actuators, and various devices, and allows individuals to effectively control the important tasks (Kasemsap, 2018b). Customer relationship management (CRM) is the significant method that deals with exploring both customer needs and customer behaviors (Kasemsap, 2018c). Exploring the relationships among e-commerce, DSSs, social media marketing, the IoT, and CRM should be further studied.

CONCLUSION

This chapter indicated the overview of e-commerce; trust and privacy issues in e-commerce; e-commerce and logistics; the applications of e-commerce; the overview of DSSs; KBDSSs; DSSs, data mining, and business intelligence; and the importance of DSSs. E-commerce is the advanced online business tool that can allow many companies to launch their websites conformed to their customers' requirements and can help customers search their specific products shown on the websites. DSSs are the computerized tools designed to facilitate the strategic decision making. With the support of data mining and business intelligence methods, DSSs can effectively increase the performance of decision making and can present the sophisticated method of managerial thinking in the timely and effective manner toward gaining competitive advantage. Utilizing e-commerce and DSSs has the potential to enhance business performance and reach strategic goals in modern business.

KEY TERMS AND DEFINITIONS

Business Intelligence: The advanced business method concerning strategic planning procedure.

Data Mining: The extraction of latent information from massive databases.

Decision Support Systems: The computer-related utilization that can help evaluate various business details toward achieving effective decision making.

Electronic Commerce: The online business approach that allows both individuals and companies to effectively conduct businesses.

Logistics: The procedure that relates to the transportation and storage of products and services.

Privacy: The term of concealing any issue from other people.

Trust: The expectation that someone or something is reliable.

This research was previously published in Improving E-Commerce Web Applications Through Business Intelligence Techniques; pages 251-270, copyright year 2018 by Business Science Reference (an imprint of IGI Global).

Chapter 33
Resources and Value Co-Creation in Social Commerce:
Evidence From Business Models in a Developing Economy – A Viewpoint for Future Research

Edward Entee
Univeristy of Ghana, Ghana

ABSTRACT

Social media (SM) is fundamentally changing the way firms conduct business and, in the process, destroying existing business models (BM). Therefore, businesses need to have a BM adaptable to social commerce (SC), which is commerce utilizing social networking services. This viewpoint for future research has questions on the types of SC BM, the value co-created by these models, and the required resources. The study proposes a framework to explore potential BM associated with social media based on their requirements and evaluate the performance of these BM. On the tenets of the study, this viewpoint argues for the need to develop BM for SC and how value is co-created and the resources underpinning this co-creation.

INTRODUCTION

Recent developments in information and communication technology (ICT) has triggered new business models (Bharadwaj, El Sawy, Pavlou, & Venkatraman, 2013; Wang & Yu, 2017a) such as social commerce (SC). Similarly, the advancement of information and communication technology (ICT) is transforming the structure of social relationships in the space between the customers and firms through social technologies such as social media and social networking sites (Susarla, Oh, & Tan, 2012). Hence, these social technologies are fundamentally reshaping traditional business strategies that enable commerce to be done across boundaries of time, distance and functions (Banker, Bardhan, Chang, & Lin, 2006;

Ettlie & Pavlou, 2006; Kohli & Grover, 2008; Rai, Pavlou, Im, & Du, 2012; Straub & Watson, 2001) a significant forte of social commerce. Thus, social commerce is the use of social media to engage in commercial activities.

Social commerce enjoys a plurality of definitions. For instance, Wang and Zhang (2012) define social commerce as "a form of commerce that is mediated by social media and is converging both online and offline environments". While Yadav and Mahara (2018) refers to social commerce as "exchange-related activities that occur in, or are influenced by, an individual's social network in computer-mediated social environments, where the activities correspond to need recognition, pre-purchase, purchase, and post-purchase stages of a focal exchange". Similarly, in an earlier definition, Liang and Turban (2011) referred to social commerce as " online commerce applications that exploit social media and web 2.0 technologies. Lai (2010), on the other hand, defined social commerce as a phenomenon that combines three concepts (Social media, Web 2.0 Technologies and e-commerce). The various definitions highlight the presence of two essential components: social media and commerce. As noted by Liang, Ho, Li and Turban (2011) and Marsden (2009), the commerce component refers to exchange-related activities that include transactions. These transactions include pre, during and post transactional activities. The second component as espoused by Yadav, Valck, Hennig-thurau, Hoffman and Spann (2013) is the computer-mediated social environment (CMSEs).

Yahoo was the first to introduce the term social commerce in 2005 (Rubel, 2006), rapidly becoming a medium of value addition by mainstay e-commerce companies such as Amazon and eBay through customer engagement (Wang & Zhang, 2012). The first academic paper to use the term *social commerce* appeared in 2006 when *flowers.com* launched its first Facebook store in 2009 saw regular use of the term in practice (Busalim & Hussin, 2016) — since then, shopping on social media networks had increased exponentially. For example, social commerce adoption among retailers in North America moved from 17 percent in 2017 to 33 percent in 2018 (Clement, 2019). This growth trend provides a promising potential for companies to invest in social media to increase consumer engagement (Wang &Yu, 2017b).

Thus, global e-commerce pioneers like Amazon and eBay are now changing their market positions with the integration of social technologies like Facebook (Du & Wagner, 2007; Fagerstrøm & Ghinea, 2010; Kim & Srivastava, 2007; Ng, 2013).

SNSs are the bedrock of social commerce because they enhance the peculiarity of the relationship between sellers and their customers (Liang & Turban, 2011). Hence, scholars have argued that online shops using social media can result in value creation and co-creation for both customers and firms (Grange & Benbasat, 2013; Kohler, Fueller, Matzler, & Stieger, 2011; Kohler, Fueller, Stieger, & Matzler, 2011). Hence, social commerce has the potential for value co-creation (Hassan & Toland, 2013). As implied by the term, "co-creation involves a symbiotic relationship between a firm and its primary stakeholders" (Kohli & Grover, 2008), and suggest that value is co-created by integrating the available resources owned by collaborators (Vargo, Maglio, & Akaka, 2008). Hence, the objective of exchange in social commerce is to connect resources and value, in this case, the value created relies on the collaborators' particular contexts (Cai, Yuan, & Zhou, 2013).

There is an exponential growth of social commerce sites (Huang & Benyoucef, 2015) and as more of these sites are springing up potentially with different services and leaning towards various models, there is a tendency for traditional firms to enter the space to earn the benefits therein. Such a venture has the potential to change their existing business processes, hence the need to align to specific organizational goals and strategy carefully.

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

From those mentioned earlier, social commerce is essential. More importantly, it is creating a situation for firms to think about carefully. With this background as the backbone of this study, it has become necessary to understand the types of social commerce business models, and how value is co-created, and the resources which underpin this value co-creation process.

JUSTIFICATION FOR THIS RESEARCH

Previous research on social commerce has examined themes including social commerce definitions and conceptual models (Busalim & Hussin, 2016; Menon, Sigurdsson, Larsen, Fagerstrøm, & Foxall, 2016; Zhang & Benyoucef, 2016), adoption (Erdoğmuş & Tatar, 2015; Farivar, Yuan, & Turel, 2016; Yahia, Al-Neama, & Kerbache, 2018), risk (Farivar, Turel, & Yuan, 2017), trust and trust performance (Cheng, Gu, & Shen, 2019), biases (Samira Farivar, Yuan, & Turel, 2016) and factors that influence customer engagement (Busalim, Hussin, & Iahad, 2019; Wongkitrungrueng & Assarut, 2018).

These studies though valuable, also highlight several gaps for future research. First, there is an absence of agreement on the definition of social commerce. For example, Menon et al. (2016) and Yahia et al. (2018) defined social commerce as a combination of e-commerce and social interaction while Wang and Zhang (2012) defined social commerce as new or emerging phenomena, which is a subset of e-commerce which converges both online and offline environments. In contrast, social commerce has been defined as selling using social media sites such as Facebook (Ngai, Tao, & Moon, 2015). This plurality of social commerce definitions gives rise to different conceptualizations of the social commerce phenomena.

Comparably, studies on social e-commerce or use of social media in e-commerce tend to be more dominant (Hajli, Sims, Zadeh, & Richard, 2017; Huang & Benyoucef, 2013; Liang & Turban, 2011; Munawar, Hassanein, & Head, 2017) and there is a call for more research on social commerce, especially on the business models and how such firms operate. The dominance exists because e-commerce/e-business (and social e-commerce) predates social commerce (Hajli, 2015; Hajli & Sims, 2015; Kim & Park, 2013). In precis, authors need to focus more on social commerce, explore the business models which underpin social commerce activities – especially examining whether e-commerce models can also apply to social commerce or whether there are new business models which underpin these firms. However, even though studies indicate that firms are leveraging emerging social commerce platforms to build relationships and engage with customers, little empirical studies exist on the value generated by these firms or the business models of social commerce firms generate value. This research attempts to address these gaps.

Concerning social commerce business models and value generation, a review published by Communications of the Association for Information Systems (CAIS) (Parameswaran & Whinston, 2007) offers some directions. The review highlighted the need to explore current and potential business models associated with social networks concerning their requirements, identify feasible models and evaluate the performance of the business models. The review further, reiterates that research into these business models need to touch on themes such as how businesses can generate value through social networks. It is instructive to note that since the publication of the review in 2007, there seem to be no studies addressing the gaps highlighted in the study. A more recent review by (Wang & Zhang, 2012) calls for future research on social commerce to identify and develop business models. Also, the authors (Wang & Zhang, 2012) emphasize the need to explore how firms manage co-creating strategies as a result of an enormous amount of content from diverse channels and platforms. On the contrary, issues such as adoption (Friedrich, 2015; Hajli & Sims, 2015), designing social commerce platforms (Mikalef, Giannakos,

& Pappas, 2017), sharing behaviour (Hsieh, Ya-Ting, & Leng-Heng, 2017), conflict and uncertainty (J. Cheng, Liu, & Du, 2017) consumer purchasing decision (Huang & Benyoucef, 2017), consumer purchase behaviour (Grange, Benbasat, & Burton-Jones, 2018), Value co-creation (Mikalef, Pappas, & Giannakos, 2017; Tajvidi, Wang, Hajli, & Love, 2017; Yu, Tsai, Wang, Lai, & Tajvidi, 2018) and Users' risk (Samira Farivar, Turel, & Yuan, 2018; Sharma & Crossler, 2014) have been studied.

Concerning theorization, another review of social commerce by Busalim and Hussin (2016) published by the International Journal of Information Management opines that the theoretical foundation of social commerce research is few and dispersed. The author of this research also, reiterate the arguments by Hajli (2014) and Wang and Zhang (2012) years earlier that development of grounded theories in this new area will be a challenge for both Information systems and strategic management researchers. A second review by Zhang and Benyoucef (2016) shows that several theories have been used to explain consumer behaviour on social networking sites. These theories used in the various studies were to test and develop explanatory models. There is the need, therefore, to consider theories that generate exploratory insights. The above assertions seem to agree with Boateng (2016), who used a strategic model to explain the complex interaction of resources as a firm seeks to integrate e-commerce capabilities with their strategic orientation.

This viewpoint further recommends the use of strategic theories to study firms in other industries and with the development of transactive and transformational capabilities. This study responds to these by adopting the Resource-Based View to explore how businesses can use resources to co-create value through social commerce.

Studies on social commerce have predominantly been from the developed, the Middle East and Asian economies perspectives (Leeraphong & Papasratorn, 2018; Qin, 2017; Vongsraluang & Bhatiasevi, 2017; Williams, 2018). Researchers in these contexts have studied issues such as articulating the drivers of social commerce (Sukrat, Mahatanankoon, & Papasratorn, 2018), factors that motivate users beyond their initial adoption to engage in post-adoption behaviors such as continuance use (Osatuyi & Qin, 2018) and social commerce acceptance among users and the factors affecting attitudes towards the phenomena (Gatautis & Medziausiene, 2014) in countries like China, Thailand, USA and Lithuania. There is also some research on social media in African countries (Jaunky, Roopchund, Ramesh, & Jaunky, 2018; Lekhanya, 2013). Despite these studies, research specifically focusing on social commerce in Africa are few (e.g. Lubua & Pretorius, 2018, 2019). These studies even though few have contributed to the use of social networks as income generation and the perceived relevance of social commerce in the African Context. However, these studies focus more on adoption and impact with little focus on strategy. Future research can draw on strategic issues to help understand further implications if we do not know successful social commerce, business models. Past e-commerce studies show evidence that firms in developing countries are always looking for technologies to become better and navigate around their constraints (Boateng, 2016). Therefore, it becomes essential that success stories of social commerce business models in Africa be studied, documented and analyzed to guide other firms.

OBJECTIVES TO BE ADDRESSED

Concerning the above research gaps, this chapter contends that future research should seek to develop a model that explains how firms create social commerce capabilities to achieve benefits. The model will offer a theoretical understanding of how social commerce firms develop, deploy and manage social

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

media as a resource to create commercial benefits. This future research will be inspired by the theory of how firms develop, deploy and manage social media as a resource to create commercial benefits. This future research must also seek to understand how social commerce firms use social media technologies to overcome their constraints. This research will not merely incorporate relevant entrepreneurship and strategic management theories in order to enrich and extend IS research; it will also contribute to Dynamic Capabilities Model by conceptualizing the development, deployment and management of social media resources to achieve benefit in the context of a social commerce firm. This future research must particularly achieve the following objectives

1. To explore the dominant business models of social commerce Firms Developing Economies.
2. To understand the value co-created by social commerce-based firms
3. To explore the resources and capabilities that underpin the value generated by social commerce business models and how the resources are deployed.

The subsequent research questions are

1. What are the dominant business models of social commerce enterprises in Developing Countries?
2. How is value co-created by social commerce-based firms?
3. What resources and capabilities underpin the value generated by the business models and how they are deployed?

THEORETICAL JUSTIFICATION

The prevailing paradigm for how firms create value using available resources is the Resource-based View. For instance, Barua, Konana, Whinston and Yin (2004) use the RBV to address the processes through which value is created through internet-enabled value chain activities. The authors further argue that a firm's abilities to coordinate and exploit its resources create higher-order resource, which leads to improved operational and financial performance. However, another study (Ray, Muhanna, & Barney, 2005) investigates the differential effects of various Information Technology (IT) resources and capabilities on the performance of the customer service process. The findings of this study suggest that tacit, socially involved, firm-specific resources explain variation in process performance and that IT resources and capabilities without these attributes do not. A third study by Sarker, Sarker, Sahaym and Bjørn-Andersen (2012) explores the value co-creation in relationships between an ERP vendor and its partners. This study found that there are different mechanisms underlying value cocreation within B2B alliance. From the studies, we learn that first, the ability of the firm to effectively combine the set of specific resources to exploit market opportunities and be competitive is the focus of the RBV (Penrose, 1959). Second, resources are " stocks of available factors that are owned or controlled by the firm"(Amit & Schoemaker, 1993).

The Resource-Based View (Barney, 1991), a dominant theory in Strategic Management literature, therefore, is used as the underlying theoretical foundation for the following reasons. First, to study social commerce-based firms' abilities to manage and deploy technological resources (for example, social media) to co-create value. The RBV theory suggests that conventional technologies can be transformed into valuable resources when used in specific business processes (Dong, Xu, & Zhu, 2009). In addition,

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

in previous IS studies the RBV has been used to study IT as a source of sustained competitive advantage (Mata, Fuerst, & Barney, 1995) and also to explain how IT value stems from the organizational use of IT than the technology itself (Clemons & Row, 1991; Markus & Soh, 1995). Second, the nature of resources required (for example, business processes) to co-create value. The RBV of the firm also stipulates that specific resources of the firm have the potential to generate sustained competitive, which will ultimately lead to superior organizational performance (Priem & Butler, 2001; Wernerfelt, 1995, 1984). These resources of the firm are categorized as tangible resources (human, physical, organizational and financial), and intangible resources (reputational, brand, trust, social and cultural) (Eisenhardt & Martin, 2000; Harrison, Hitt, Hoskisson, & Ireland, 2001). Third, how value co-creation is developed through external relationship management as cited by (Wade & Hulland, 2004), this is important because the main focus of social commerce-based firms is to exploit the use of the social technologies for value co-creation in interactions with their customers and other external partners.

The central theme of the RBV addresses the fundamental question of why firms are different and how they achieve and sustain competitive advantage by deploying their resources (Kostopoulos, Spanos, & Prastacos, 2002). Similarly, RBV has been used as a paradigm that combines different philosophies and frameworks from various disciplines (Mahoney & Pandian, 1992; Wade & Hulland, 2004). The RBV also posits that firms possess resources; a part of these resources enables the firms to achieve competitive advantage; another part of it leads to superior sustained performance (Barney,1991).

The author further reiterates that these resources, which are composed as heterogeneous resources, can create a competitive advantage if they have the following qualities:

Valuable: the resource can enable a firm to conceive or implement strategies that improve its efficiency or effectiveness;
Rare: a large number of competing firms should not possess the resources
Imperfectly Imitable: the resources should not be easily imitated due to unique historical conditions, causally ambiguous, or social complex;
Non-Substitutable: Other substitutes should not easily replace the resource.

However, advocates of RBV are unable to have a precise definition of what a resource is (Butler & Priem, 2001). This proliferation of definitions and classifications has raised complex issues in studies using RBV as it is unclear what these researchers mean the term “resources” (Butler & Priem, 2001).

CONCLUSION

The chapter has argued the need to identify and develop a model that explains how social commerce-based firms co-create value using available resources to achieve benefits. The significance of this research can be viewed from academic, practitioner and policy perspectives. In scholarship discourse, the development of social commerce research, like other fields of study, requires theorization and development of a conceptual framework.

From the research perspective, this research will reveal based on a theory the value that social commerce enterprises benefit from leveraging social media and web 2.0 technologies. This research cannot be overlooked because the research seeks to add to the existing body of knowledge regarding social

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

commerce studies as well as to research gaps considering the paucity of studies on social commerce business models.

Regarding policy and practice, this research will inform practitioners about the resources needed to develop social commerce capabilities. This research will also provide adequate findings for Governments as well as other regulatory bodies to formulate policies and laws to govern the use of the internet and also use that as a means of job creation.

Chapter 34
A Novel Fuzzy Integrated Customer Needs Prioritization Software Tool for Effective Design of Online Shopping Websites

Ashish K. Sharma
Manoharbhai Patel Institute of Engineering and Technology, Department of Computer Technology, Gondia, India

Sunanda Khandait
KDK College of Engineering, Department of Information Technology, Nagpur, India

ABSTRACT

Albeit, online shopping has grown much recently, users' rate of satisfaction has declined due to the ineffective design of online shopping websites. Thus, the companies involved are craving for well-designed websites. Effective website design involves decision making and thus this paper considers Quality Function Deployment (QFD) as it is a strong decision-making tool. However, QFD uses crisp scoring approach that generates uncertainty and vagueness resulting in impreciseness and inconsistency in results. The issue can be addressed using fuzzy integration. QFD involves prioritization of Customer Needs (CNs) and Technical Requirements (TRs). However, the paper focuses on only CNs prioritization. Also, the existing software's lack the indispensable fuzzy support feature to handle the uncertainty and vagueness. Thus, the paper presents a novel fuzzy integrated customer needs prioritization software tool. The tool is built using Visual Basic Dot Net (VB.Net) and MS-Access. A real-life example is presented to demonstrate the viability of the software tool.

INTRODUCTION

The popularization and rapid development of the Internet has made online shopping emerged as hot area amongst customers with more number of customers now opting for online shopping (Kuo & Chen, 2011). As a result, there has been explosive growth in the use of online shopping. Although online shopping has become a growing new trend, the satisfaction rate of users has descended due to poor design of websites (Kuo, 2006). The website design has come out as major driving force behind the success of online shopping websites (Sharma & Khandait, 2015). A well-designed website helps strengthen the firm's brand equity, while a badly designed website can diminish the established brand equity. Moreover, an effective web design increases perceived trust of customers (Johnson & Griffith, 2002). Thus, businesses engrossed in online shopping are paying serious attention to effective design of shopping websites. Effective website design involves decision making at several stages of the process. This paper considers Quality Function Deployment (QFD) approach as it greatly assists designers and engineers in efficiently carrying out design decisions. QFD provides a way to translate conceptual requirements into items that are workable, measurable and capable of design enhancement resulting in better design, shorter product development cycles, better product quality and lower costs (Lin, Tsai, Cheng & Chang, 2004). In QFD, an effective prioritization leads to better results and hence to successful design and development. Two of the main areas, which call for prioritization in QFD, are Customer Needs (CNs) and Technical Requirements (TRs). However, this paper only considers CNs prioritization.

In QFD, the design team has to create, improvise, innovate or improve a product by integrating the CNs into a product. As it is not possible to go by all CNs because of the time, money and efforts constraints, the design team needs to make trade-offs while picking the CNs on the basis of order of their raw weights and ranking to achieve more customer satisfaction (Sharma & Rawani, 2007). Also, the conventional QFD uses linguistic expressions e.g. 'weak', 'average' and 'strong' generating ambiguity. Computing these ambiguities is a key issue. These linguistic terms are then scaled into crisp values (e.g. 1-3) for the ranking of each alternative. This crisp assessment poses difficulty in coping with uncertainty among design team members (Masud & Dean, 1993). Although the quality can be greatly improved through a QFD, the conventional crisp scoring approach has a major drawback. A wrong conclusion can be easily produced since the fuzzy nature of linguistic relationship terms from evaluation members is ignored (Lin, Tsai, Cheng & Chang, 2004). The issue can be resolved by handling the uncertainty and vagueness involved in the process. This can be accomplished using fuzzy integration with QFD. The fuzzy concepts have been successfully applied in decision making problems. (Pattnaik, 2015) has applied decision making approach to fuzzy linear programming problems with post optimal analysis. (Singh, Chauhan & Singh, 2015) presented an application in tourism industry using multi criteria futuristic fuzzy decision hierarchy in swot analysis. (Rabbani, Mamaghani, Farshbaf-Geranmayeh & Mirzayi, 2016) presented a novel mixed integer programming formulation for selecting the best renewable energies to invest, using a fuzzy goal programming approach. The fuzzy set theory is a useful tool for solving problems where the descriptions of objects are subjective, vague and imprecise.

The available softwares' may overcome the issue of prioritization of CNs but they strongly lack the much-needed fuzzy support to handle the uncertainty and vagueness and affinity support to generate CNs from the collected Customer Voices (CVs) (Sharma & Khandait, 2016). This generates a pressing need for a customized software tool to serve the purpose. To this end, the paper aims to develop a novel fuzzy integrated customer needs prioritization software tool for effective design of online shopping websites. The most integral part of QFD is House of Quality (HOQ). Over the years several HOQs have

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

been proposed and reported by researchers. The proposed software tool is founded on the HOQ model proposed by (Chan & Wu, 2005). The tool is developed using Visual Basic Dot Net (VB.Net) and MS-Access. The tool employs Symmetrical Triangular Fuzzy Numbers (STFNs) to deal with the involved uncertainty. A real-life example is presented to demonstrate the viability of the developed software tool.

LITERATURE REVIEW

QFD is customer driven product development process that strives for high quality in the product and improved customer satisfaction (Sharma, Mehta, & Sharma, 2010). QFD is an innovative approach bringing quality – as demanded by the customers – upstream into the product development process (Akao, 1990). The principle of QFD is similar - the idea is to take the customer into the development process to ensure that the core quality will be in the product or service - the customer satisfaction (Kivinen, 2006). The integral part of QFD is House of Quality (HOQ). QFD is said to have been first proposed in Japan by Yoji Akao in 1966. Ever since QFD came into existence it has been extensively used in various areas like Product Development (Anthony & Dirik, 1995), Web Design (Barutchu, 2006), Decision Making (Chuang, 2001) (Liao & Kao, 2014), Software (Zahedi, Yousefi & Cheshmberah, 2011) (Sharma, Sharma & Mehta, 2012), Operation Research (Karsak et al., 2003), Education (Agrawal & Sharma, 2014) etc. to name a few.

A few approaches have been introduced for the determination of CNs importance rating in the QFD process. (Nahm, Ishikawa & Inoue, 2013) have proposed new rating methods to prioritize customer requirements in QFD with incomplete customer preferences. (Franceschini, Maisano & Mastrogiacomo, 2015) has discussed a new proposal based on the generalized Yager's algorithm for customer requirement prioritization in QFD. (Kamvysi, Gotzamani, Andronikidis & Georgiou, 2014) have used embedded Fuzzy-AHP and linear programming in QFD to capture and prioritize students' requirements for course design. (Yi-zeng & Qi, 2014) used a fuzzy game method to prioritize customer needs in QFD. (Wang & Chin, 2011) proposed a linear goal programming approach to determine the relative importance weights of CNs. (Perini, Susi & Avesani, 2013) presented a machine learning approach to software needs prioritization.

There are a few software tools, which facilitates using QFD. Some of the QFD software tools that are offered at the German and the international market are 'QFD Capture 3.1, 'HyperQFD' by Qualica Software GmbH, Germany. Qualisoft from USA provides 'QFD Designer 3.15'; 'QFD work' by Total Quality Software, Great Britain. 'QFD DesignerQS' by QS Software. 'QFD Builder' is browser-based software that facilitates users to build, store, and share their HOQ online (qfdonline.com). 'PathMaker' is software by NOWECO that aids in defining all the steps required to run QFD. IDEACore provides 'QFD Designer v 4.0' which is windows based software (ideacore.com). Even though these software's provide many features that could help the designers and engineers of QFD team, but neither of these facilitates the much-needed fuzzy support option to handle the vagueness and uncertainty involved.

QUALITY FUNCTION DEPLOYMENT

Quality Function Deployment (QFD) is customer driven cross working planning tool used to boost business potentials, while exploiting company objectives. At first, QFD was deliberated and implemented

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

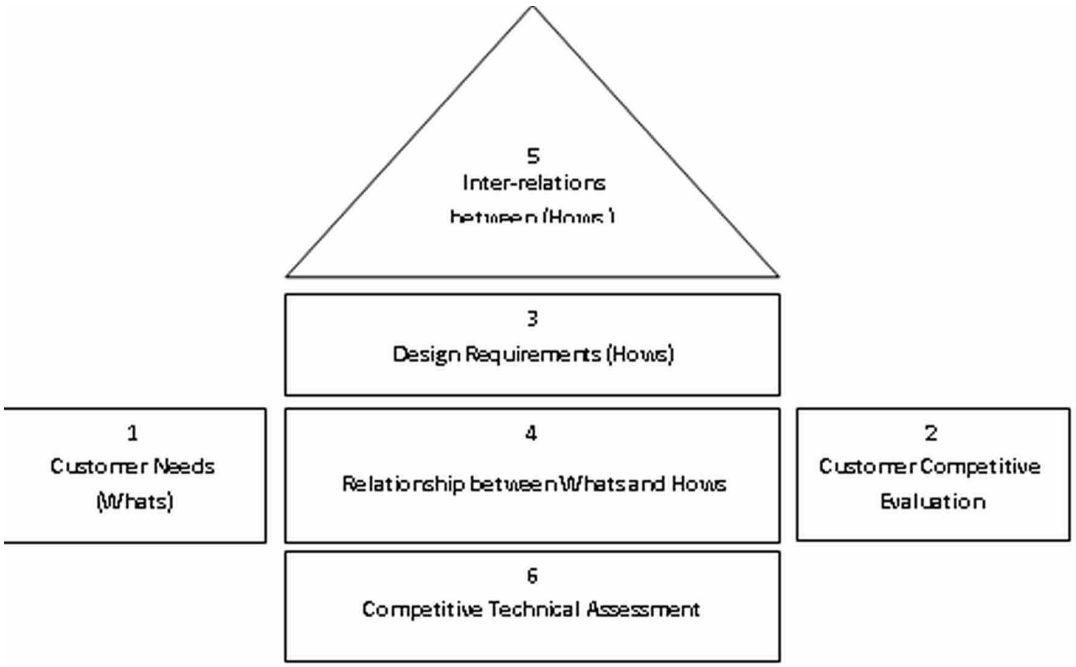
by Yoji Akao in the late 1960. QFD is prominent tool used for developing a design quality aimed at satisfying the consumer and then translating the consumer's needs into design requirements (Akao, 1990). QFD is one of the most important methods to satisfy the customers and to transform customers' needs into design aims (Barutchu, 2006). QFD methodology provides a way to translate conceptual needs into items that are workable, measurable and capable of design enhancement. The result is a better design, shorter product development cycles, better product quality, and lesser costs (Lin, Tsai, Cheng & Chang, 2004). QFD is strongly based on the Four Phase Model which represents product planning, component planning, process planning and production planning (Cohen, 1995). The most significant tool of the QFD is the matrix chart called House of Quality (HOQ) as shown in Figure 1. This tool generates specific, prioritized, and measurable design requirements from often-ambiguous customer needs. The HOQ matrix is the most accepted form of QFD. HOQ is the matrix, which evaluates customer needs in detail and translates them into the developer's language (Griffin, 1992).

House of Quality

HOQ can be modeled via various steps as stated by (Zaim & Sevkli, 2002):

1. Identify Customer Needs
2. Customer Competitive Evaluation
3. Develop Technical Requirements
4. Relationship between What's and How's
5. Correlating Technical Requirements
6. Competitive Technical Assessment

Figure 1. House of quality – QFD (Zaim & Sevkli, 2002)



EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

FUZZY CONCEPTS

Decision making encompasses dealing with doubts, vagueness and uncertainties. Probability theory can represent the stochastic nature, but fails to measure the inaccuracies or uncertainty that stem from human behavior. Sometimes when the values cannot be defined precisely, the evaluations or opinions are expressed in linguistic terms and so on (Bevilacqua, Ciarapica & Giacchetta, 2006) (Zahedi, Yousefi & Cheshmberah, 2011). Fuzzy logic can be used in such situations. Fuzzy logic and fuzzy sets were introduced in 1965 by Professor L.A. Zadeh. Fuzzy logic approach is based on "degrees of truth" rather than the usual "true or false" (1 or 0) Boolean logic on which the modern computer is based. Fuzzy logic uses human linguistics understanding to express the knowledge of a system consisting of facts, concepts, theories, procedures, and relationships and is usually expressed in the form of IF-THEN rules. In fuzzy logic theory, a linguistic variable can belong to more than one group. For example, someone who is 27 years old belongs to both the "young" and "not so young" group at a different degree (Zaim and Şevkli, 2002). Fuzzy analysis is capable of dealing with qualitative or imprecise inputs from designers by describing the performance of each criterion with some linguistic terms, such as "good", "poor", "medium", etc. These linguistic terms can be represented and manipulated based on fuzzy set theory. A broader view on the fuzzy set theory and STFNs has been provided by (Chan & Wu, 2005).

The fuzzy set theory is most suited for solving problems where objects descriptions are subjective, vague and imprecise. Let $X = \{x\}$ be a traditional set of objects, called the universe. A fuzzy set F in X is characterized by a membership function $\mu_F(x)$ that associates each object in X with a membership value in the interval (0,1), indicating the degree of the object belonging to F. A fuzzy number is a special fuzzy set when the universe X is the real line R^1: $-\infty < x < +\infty$. A STFN denoted as $F = (p, q)$ is a special fuzzy number with the following symmetrical triangular type of the membership function:

$$\mu_F(x) = 1 - | x - (q + p) / 2 | / ((q - p) / 2) \text{ where } p \leq x \leq q$$

STFN is widely used in practice to represent a fuzzy set or concept F = "approximately r" where $r = (p + q) / 2$. Thus, to capture the vagueness of customer subjective assessment on a particular CN having a crisp value 7 can be represented using STFN (6,8) and the membership function for this is:

$$\mu_{(6, 8)}(x) = 1 - | x - 5 | \text{ where } 6 \leq x \leq 8$$

The basic arithmetic rules for STFNs are as follows:

- **Addition:** $(p1, q1) + (p2, q2) = (p1+p2, q1+q2)$
- **Subtraction:** $(p1, q1) - (p2, q2) = (p1-q2, q1-p2)$
- **Multiplication:** $(p1, q1) * (p2, q2) = (p1p2, q1q2), p1 \geq 0, p2 \geq 0$
- **Division:** $(p1, q1) / (p2, q2) = (p1/q2, q1/p2), p1 \geq 0, p2 \geq 0$

PRIORITIZATION OF CUSTOMER NEEDS

The suitable assessment of CNs is greatly required in QFD as it drives the decision making. This is done through prioritization of CNs. The various steps involved in prioritization process as stated by (Chan and Wu, 2005) are:

Step 1: Identify the Product and the Key Competitors

The first step is to identify the product to which the QFD is being applied and the key competitors who offer relatively the same product, for evaluation and comparison:

Brand Model on which QFD is done (Own Firm): 'OF'. Competitors: 'F1' and 'F2'.

Step 2: Identify the Customers

The QFD is a customer driven process and hence the identification of customers is very important. Customers can be identified through previous information and marketing research:

Customers (C) - C_1, C_2, C_3, …, C_c, …, C_z ; C_c - c^{th} Customer; c = 1 to z; z - Number of Customers

Step 3: Determine Customer Voices

Customer Voices (CVs) or opinions are one of the biggest sources for product or service improvement as QFD is driven by the voice of customer. Customer voices are the statements or opinions expressed by customers in their own words. Once the customers are selected then the next step is to determine directly from the customers what they expect from a particular product. The customer voices are very significant and are usually gathered through several marketing research techniques like surveys, interviews, focus group, brainstorming, using existing information etc.

Step 4: Generate Customer Needs

This is very crucial step as it involves processing customer voices so as to generate customer needs. This requires processing, limiting and organizing the data through brainstorming. This is done by using the affinity process. The data gathered from the customers' results in massive unsorted and disorganized data, which represent customer voices. This data is required to be altered into a handful of statements that conveys the actual key customer needs. These customer needs are then to be grouped into a category with affinity for better analysis. Limiting and organizing the customer needs is important as the task becomes increasingly onerous as the number of input grows. A requirement list of more than 50 is not recommended. Albeit the optimum number of CNs depends strongly on the particular project, 20 to 25 can be considered a good compromise between grade of detail and complexity. As the matrix grows, it will lead to signs of fatigue and loss of interest leading to diminished output. Thus, it is important to limit the number of CNs. This is done through the affinity process, an efficient method of organizing large amounts of unstructured verbal data. It enforces a high degree of organization and screen-hidden relationships between the items and item groups. The final outcome of the affinity process is a tree

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

structure with elements at primary, secondary and tertiary level where elements at tertiary level represent the actual generated customer needs:

Customers Needs (CN) - CN_1, CN_2, CN_3…, CN_j, …, CN_m

CN_i - i^{th} Customer Need; i = 1 to m; m - Number of Customer Needs

Step 5: Prioritize Customer Needs

Customer Importance Ratings

Most important CNs as per customers' perception is to be elicited out. Although all CNs are probably important, it is necessary to know their relative importance. The relative importance is expressed as a set of ratings that can be determined by letting the customers disclose their perceptions on the relative importance of CNs and then averaging their perceptions. These ratings are called as Customers Importance Ratings (CIR) and are given by the Scales (1) and (2) for crisp and fuzzy mode:

- Customers Importance Ratings (CIR) - CIR_{11}, CIR_{12}, CIR_{13}, …, CIR_{ci}, …, CIR_{zm}
- CIR_{ci} - Customers Importance Ratings of c^{th} Customer for i^{th} Customer Needs
- $CIR_i = (\Sigma CIR_{ci}) / z$
- CIR_i - Mean Value of Customers Importance Ratings for i^{th} Customer Need

Crisp Scale: 1: Very Low; 3: Low; 5: Moderate Important; 7: High; 9: Very High (1)

Equivalent Fuzzy Scale: (0, 2); (2, 4); (4, 6); (6, 8); (8, 10) (2)

Customer Satisfaction Ratings

Customer Satisfaction Ratings (CSRs) is the customer perception regarding the product performance used as a basis for the comparison between the company and its competitors. This involves doing Customer Competitive Analysis (CCA) by identifying competitors who produce similar products and then determining how the customer perceives the competitors' ability to meet each of the requirements. This is done by asking the customers to rate the relative performance of the company and its competitors on each CN and then to aggregate the customers' ratings. The Scales (3) and (4) are used for these ratings:

- Customers Satisfaction Ratings (CSR) - CSR_{111}, CSR_{112}, CSR_{113}, …, CSRcik, …, CSRzmf
- CSR_{cik} - Satisfaction Ratings of c^{th} Customer for i^{th} Customer Need using k^{th} Firm's product
- k = 1 to f; f - Number of Firms / Competitors
- $CSR_{ik} = (\Sigma\ CSR_{cik}) / z_k$; z_k – Number of Customers for k^{th} Firm's product
- CSR_{ik} – Mean Value of Satisfaction Ratings of for i^{th} Customer Need using k^{th} Firm's product

Crisp Scale: 1: Very Poor; 3: Poor; 5: Neutral; 7: Good; 9: Very Good (3)

Equivalent Fuzzy Scale: (0, 2); (2, 4); (4, 6); (6, 8); (8, 10) (4)

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Customer Competitive Priority Rating

The next step is to compute the Customer Competitive Priority Ratings (CCPR) on CNs for the producing company 'own firm'. This set of priority rating is derived by using more objective Entropy method and are given by CCPR = ($CCPR_1$,$CCPR_2$,$CCPR_3$,…, $CCPR_m$) where $CCPR_m$ is company 'Own Firm' priority rating on customer need CN_m. Entropy is a measure for the amount of information or uncertainty, variations represented by a discrete probability distribution p_1,p_2,…, p_L:

$CCPR\ (p_1, p2, \ldots, p_L) = -\varnothing_L$

where $\varnothing_L = 1 / \ln(L)$ is a normalization constant to guarantee $0 \leq CCPR(p_1, p_2, \ldots, p_L) \leq 1$. Larger entropy or CCPR (p_1, p2, …, p_L) value implies smaller variations among the p_l's and hence less information contained in the distribution. Larger the CCPR (CN_m) value, the less information contained in CN_m. If all companies' performance ratings on CN_m are same, CN_m has zero variations and CCPR (CN_m) achieves its maximum of 1. So CCPR (CN_m) can be used to reflect the relative competitive advantage in terms of the customer need CN_m with a larger $CCPR_m$ indicating higher competitive priority for the corresponding CN_m.

Goal

Goal denotes our future products. It indicates as to what level the organization is trying to achieve with regard to each and every need of the customers. The performance goals are set on CNs according to 'own firm' current performance in relation to its competitors. The set of goal values generated is given by G = (G1, G2, G3, …, GM).

Usually the goal set is more than the current performance goal value which implies the need or desire for further improvement:

Gi - Goal of ith customer need; i = 1 to m

Improvement Ratio

Improvement Ratio (IR) is the attempt level needed to attain targeted goals and is calculated as the ratio of Goal to the customer satisfaction rating:

- Improvement Ratio (IR) are denoted as - IR_{11}, IR_{22}, IR_{33}, …, IR_{mf}, …, IR_{MF}
- IR_{mf} - Improvement Ratio of m^{th} Customer Need for f^{th} Firm
- f = 1 to F
- F – Number of Firms
- Improvement Ratio = Goal / CSR i.e. $IR_{mf} = G_m / CSR_{mf}$

Raw Weights

Raw Weight (RW) indicates the overall importance of the CNs and is calculated by the product of CIR_m, $CCPR_m$ and the IR_m as shown in Table 1. The more value of RW, the higher the priority. This value

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

indicates where the design team should focus its attention in order to address what is important to the customers. RWs are shown in Table 1:

- Raw Weight (RW) - RW_1, RW_2, RW_3, …, RW_m, …, RW_M
- Raw Weight = Importance Rating * Competitive Priority Rating * Improvement Ratio
- RWm = CIRm * CCPRm * IRm

Table 1. Customer needs and their raw weights

SOFTWARE TOOL DESCRIPTION

The proposed software tool is designed and built using VB.Net and MS-Access and the software interface is shown in Figure 2. The interface acts as a junction to interact with human being and allows for effective operations and control of the machine from the human end. An interface comprises of commands or menus through which a user communicates. The interface of proposed software tool includes a main menu that facilitates various needed options like creating customers, competitors, building customer table etc. The menu is composed of five buttons namely – 'Create', 'C-Table', 'T-Table', 'Reports' and 'Exit':

- **'Create':** It provides creation of product, customers and competitors or firms;
- **'C-Table':** It assist in building of customer table;
- **'T-Table':** It facilitates the building of technical table;
- **'Reports':** It aids in creation of various reports which can be printed;
- **'Exit':** It is used to end the application.

The 'C-Table' is generated when all the steps of prioritization of CNs are accomplished. The interface shown is for a complete QFD application. Since this paper only considers the prioritization of CNs, only the related menus –'C-Table' and 'Reports' forms the topic of discussion here. The complete process is depicted through flowchart in Figure 3. The tool focuses on the suitable data input and processing of various parameters like CVs, generation of CNs from CVs, ratings and other related parameters so as to generate the final outcome as ranking of CNs using crisp and fuzzy mode and providing necessary database support which in turn is required to provide several reports. When the application is run, user is presented with the screen as shown in Figure 2.

The customers and competitors are created at first. This is done by clicking 'Create' button which pops up the 'Create' form as shown in Figure 4. The same form allows for creation of Customers or Competitors. The 'CreateNew' dropdown can be used to select Customer or Competitor depending on what the user needs to create. The information is then entered and saved by clicking the 'Save' button. The data can be updated and deleted through 'Edit' and 'Delete' buttons. 'Next' option is then activated to jump to the form as shown in Figure 5 for entering customer voices. The form can be used to create, update, delete and save CVs. The 'Next' button is then invoked to jump to next window in order to generate CNs. This is done by processing CVs through brainstorming using affinity process and thus the first step involves filtering the CVs. Filtering CVs involve removing repetitive data, identifying similar set of elements, translating negative statements into positive statements and then replacing them by some meaningful information. This is done using Figure 6. Multiple CVs can be selected through checkboxes and then replaced by entering 'Replacement Value' followed by clicking 'Replace' button. This removes the checked items from the list and the replacement value is inserted in their place. The data can be modified, deleted or saved to the database. The outcome of the filtration process yields processed CVs which are then transformed into tree structure comprising of primary, secondary and tertiary level elements so as to generate CNs from it. The extraction of tertiary level elements gives actual generated CNs. This is achieved using the form as shown in Figure 7 and which can be accessed by clicking 'Next' button. The interface employs a set of buttons to facilitate the organization of elements. The buttons carry out the following functions – 'Create', 'Delete' and 'Rename' groups. The elements can be dragged and dropped from 'Listview' to 'Treeview' to generate tree structure. When the tree is completed the elements at tertiary level represents the generated CNs. The tree structure can be saved to the database using the 'Save' button. The interface provides 'Load' button to fetch and load the saved tree structure from database and show in tree view. Once the CNs is generated the next step involves input of importance and satisfaction ratings for CNs which are done through the forms shown in Figure 8 and 9 respectively. The ratings are entered using scale 1-5 as shown in Figure 8 and Figure 9 respectively.

The entered ratings can be viewed by selecting 'ShowCIR' and 'ShowCSR' checkboxes. After the ratings are entered, competitive analysis is done for all CNs which involves building Customer Competitive Matrix (CCM) and which is obtained by averaging the customers' assessments. The Customer Competitive Priority Rating (CCPR) is then computed on the basis of CCM followed by setting Goal values, computing Improvement Ratios (IRs) and generating Raw weights (RWs). This is done through the form as shown in Figure 10. As seen, the interface provides a set of checkboxes 'CIR', 'CSR', 'CCPR', 'Goal', 'I-Ratio' and 'RW' to serve the purpose. The checkboxes are activated in sequence from left to right to generate data in grid.

RWs are the main outcome of the CNs prioritization process. When 'RW' option is selected, the RWs are generated as Crisp Raw Weight (CRW), Fuzzy Raw Weight (FRW), Scaled Crisp Raw Weight (SCRW) and Scaled Fuzzy Raw Weight (SFRW). The crisp values are converted into its equivalent fuzzy numbers using the algorithm given in Listing 1 below. The conversion yields Symmetrical Triangular Fuzzy Numbers (STFNs). The generated RWs both crisp and fuzzy are then scaled to have maximum ratings of unity for better comparison.

Listing 1: Algorithm to Generate Fuzzy Number from Crisp

1. Read the crisp value from the cell of grid
   a. C= crisp value
2. Generate left or lower limit of fuzzy number
   a. Left_value = C-1
3. Generate right or upper limit of fuzzy number
   a. Right_value = C+1
4. Create string using left and right value separated by comma.
5. Left_value & "," & Right_value
6. Assign this to string variable to represent
7. Fuzzy Value
8. Fuzzy_value = Left_value & "," & Right_value
9. Replace the crisp value with this Fuzzy_
10. value in cell
11. Repeat for all the cells in the grid

For crisp RWs, the scaled values are obtained by dividing all RWs of CNs by their maximum and for fuzzy RWs, the scaled values are obtained by dividing all fuzzy RWs of CNs by maximum of their upper limits. The 'Show Ranked CNs Crisp and Fuzzy' option can be used to generate the final ranked CNs based on scaled values, using crisp and fuzzy approach. When selected, both the ranked CNs crisp and fuzzy is shown in grid under the columns 'CRank' and 'FRank'. These ranked CNs can then be saved to database using 'Save' button. The ranking is done as per the values of RWs of CNs. CNs with highest RW is ranked 1, second highest ranked 2 and so on. Ranked CNs can be viewed graphically by selecting 'Graphical View Ranked CNs'. When selected, the ranked CNs - both crisp and fuzzy are presented in graphical form.

A REAL-LIFE EXAMPLE

In order to exhibit the viability of the proposed system, the paper considers an example of an Online Shopping Website with the following sample set of data. The example makes use of 14 CNs, 2 Competitors 'F1' and 'F2'. 'OF' represents own firm for which QFD is applied. The Competitors and their Ids are listed below. The CNs used is depicted in Table 2. The software tool is run with the sample set of data and the step by step generated screenshots are depicted in Figure 11, Figure 12, Figure 13, and Figure 14:

- **Product:** *Online Shopping Website*
- **Customer Needs (CNs):** *CN1 to CN14*
- **OwnFirm:** *OF (Id:500)*
- **Competitors***: F1 (Id:501) and F2 (Id:502)*

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 10. Ranked CNs (crisp and fuzzy)

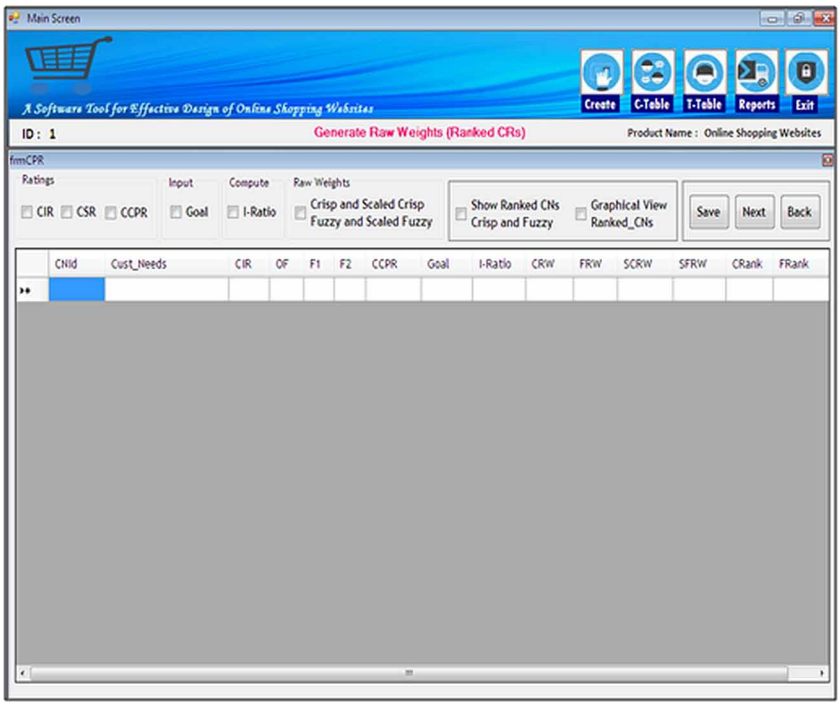

Table 2. Customer Needs (CNs)

CN_Id	Customer Needs	CN_Id	Customer Needs
CN1	Attractive Appearance	CN8	Multi-Format-Buy Support
CN2	User Friendly Interface	CN9	Ideal/Efficient Checkout Utility
CN3	Less Screen Complexity	CN10	Efficient Customer Support
CN4	Acceptable Download Times	CN11	Free Shipping
CN5	Powerful Search	CN12	Timely /Faster Delivery
CN6	Easy Product and Price Comparison	CN13	Customers Data Security
CN7	Visualization Of Products	CN14	Payment Security

RESULTS AND DISCUSSIONS

The computation of RWs yields the final outcome as prioritized CNs. The CNs are ranked or prioritized as per the values of generated RWs. The CN with highest value of RWs is ranked 1, second highest as ranked 2 and so on. The generated RWs and the rank for all CNs using both crisp and fuzzy approach are shown in Figure 15 for comparison. It can be deduced from the results that 'Customers Data Security' turned out to be most significant CN with rank 1 followed by 'Payment Security', 'Easy Product and Price Comparison' and 'Powerful Search' having ranked 2nd, 3rd, and 4th respectively using both crisp and fuzzy approach. According to crisp approach, the CNs - 'Efficient Customer Support' and 'Timely/ Faster Delivery' stood as 5th and 6th important CN. However, going by fuzzy approach, it is realized that

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

both these CNs share almost identical range (0.5847, 0.7789) and (0.5836, 0.7724). This indicates that considering fuzzy approach, the 5th and 6th CNs carry equal importance and hence share same rank. The CN - 'User Friendly Interface' is ranked 7th using the crisp and fuzzy approach.

Figure 11. Created and filtered customers voices

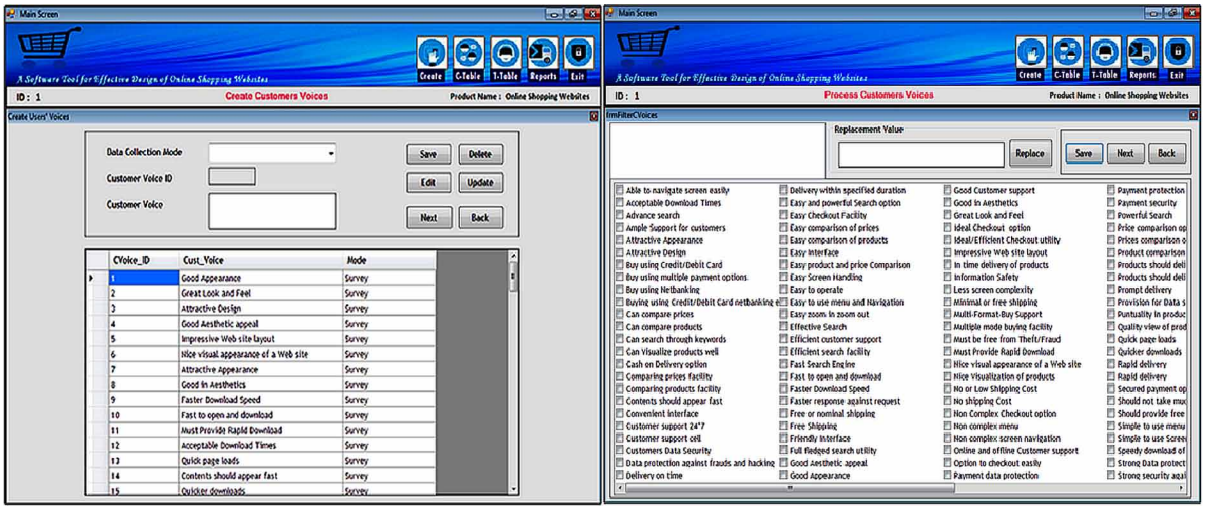

Figure 12. Generated Customer Needs (CNs)

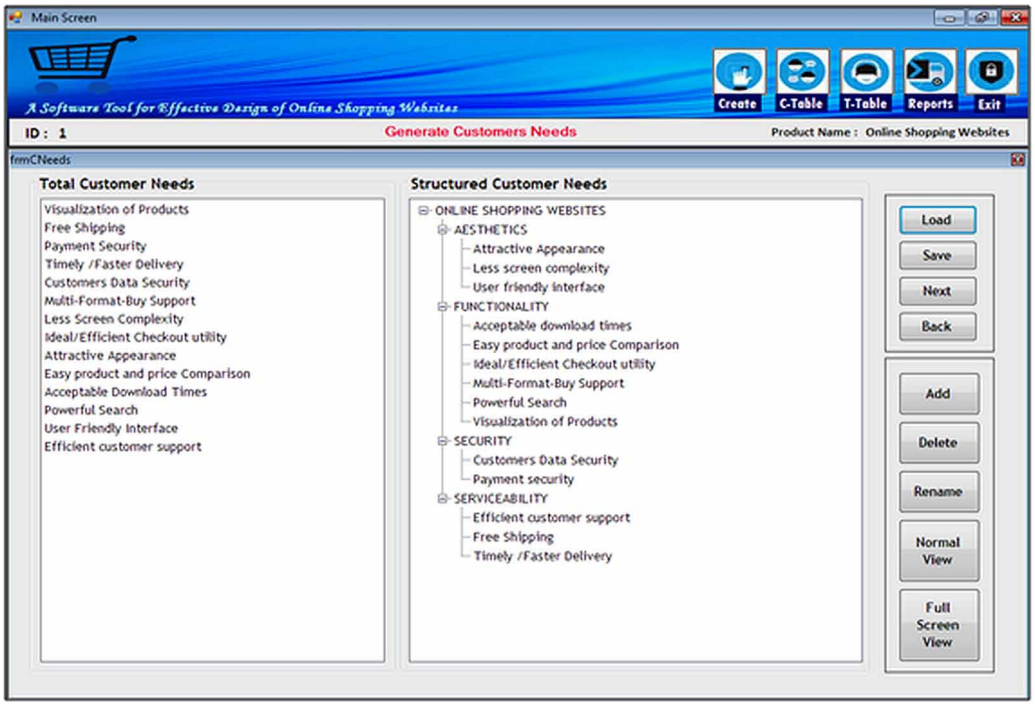

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

Figure 13. Entered ratings - CIRs and CSRs

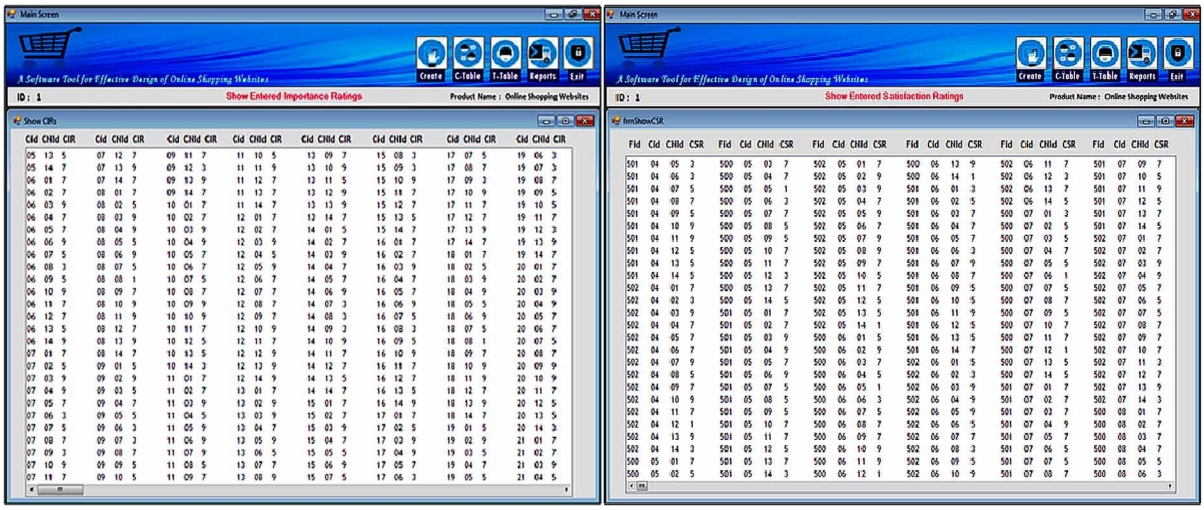

Figure 14. Generated raw weights and ranked CNs (graphical view) using crisp and fuzzy

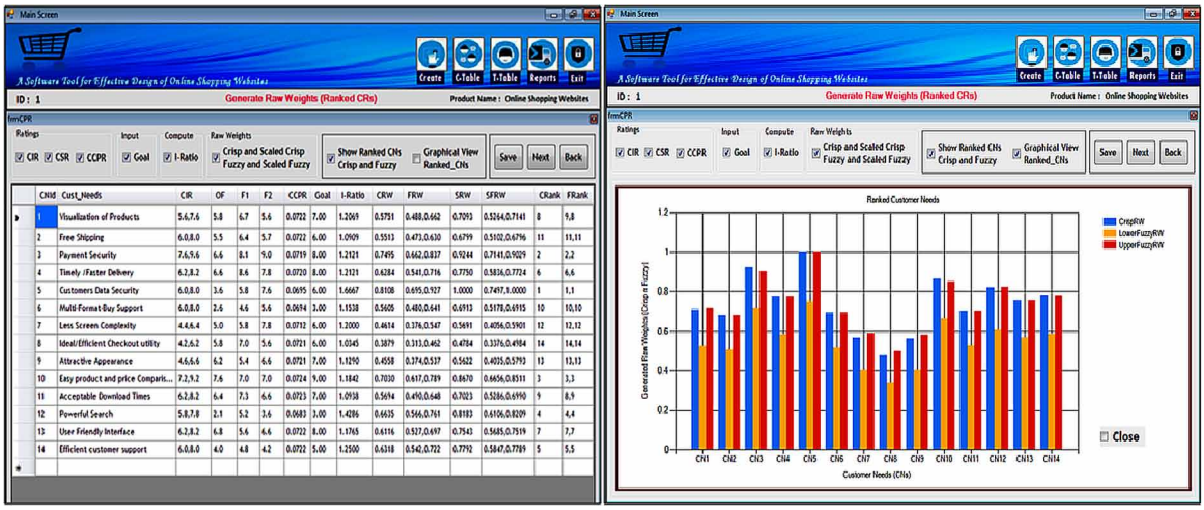
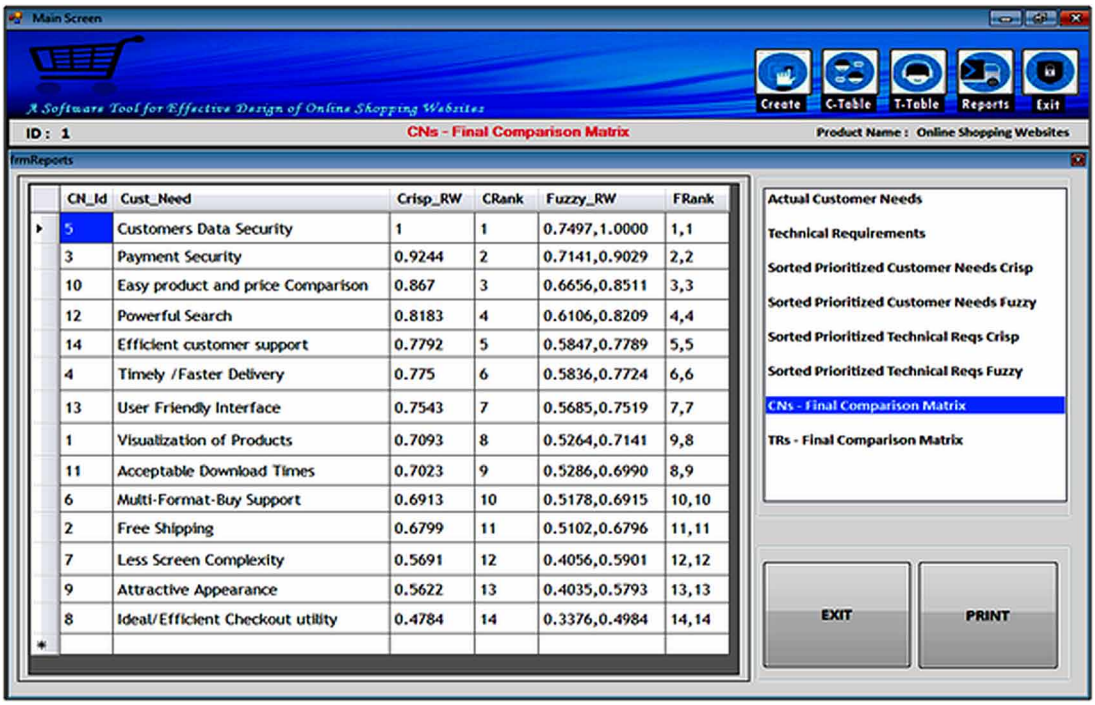


The CNs - 'Visualization of Products' and 'Acceptable Download Times' are ranked as 8th and 9th. However, there is difference in the ranking order considering crisp value and lower limits of fuzzy number. 'Multi-Format-Buy Support' and 'Free Shipping' hold the position as 10 and 11 respectively as per the rank using the crisp and fuzzy approach. The CNs - 'Less Screen Complexity', 'Attractive Appearance', and 'Ideal/Efficient Checkout Utility' are determined as least or minimal important CNs. It could be inferred through analysis of crisp and fuzzy values of raw weights of CNs that the crisp values are much closer to the upper limits of the corresponding fuzzy values while they differ greatly from the lower limits of fuzzy values (Refer Fig. 15). For example, for the CN – 'Efficient Customer Support' the crisp and fuzzy raw weights values are 0.7792 and (0.5847, 0.7789) respectively. The fuzzy approach results in the ratings expressed in ranges of values. This would provide clearer picture about the CN and gives

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

better illustration of the variations of CNs as compared to crisp. This implies fuzzy approach is more useful and of great assistance as compared to crisp. The fuzzy approach provides a broader view of the variations of CNs and thus improves the reliability of the decisions. This helps is suitable evaluation of CNs which in turn will lead to better and effective design.

Figure 15. Ranked CNs using crisp and fuzzy approach



CN_Id	Cust_Need	Crisp_RW	CRank	Fuzzy_RW	FRank
5	Customers Data Security	1	1	0.7497,1.0000	1,1
3	Payment Security	0.9244	2	0.7141,0.9029	2,2
10	Easy product and price Comparison	0.867	3	0.6656,0.8511	3,3
12	Powerful Search	0.8183	4	0.6106,0.8209	4,4
14	Efficient customer support	0.7792	5	0.5847,0.7789	5,5
4	Timely /Faster Delivery	0.775	6	0.5836,0.7724	6,6
13	User Friendly Interface	0.7543	7	0.5685,0.7519	7,7
1	Visualization of Products	0.7093	8	0.5264,0.7141	9,8
11	Acceptable Download Times	0.7023	9	0.5286,0.6990	8,9
6	Multi-Format-Buy Support	0.6913	10	0.5178,0.6915	10,10
2	Free Shipping	0.6799	11	0.5102,0.6796	11,11
7	Less Screen Complexity	0.5691	12	0.4056,0.5901	12,12
9	Attractive Appearance	0.5622	13	0.4035,0.5793	13,13
8	Ideal/Efficient Checkout utility	0.4784	14	0.3376,0.4984	14,14

CONCLUSION

This paper considers QFD approach as QFD is strong decision making tool and decision making forms the basis in effective web design. In QFD, the prioritization of CNs and TRs is done. However, the paper only focuses on the CNs prioritization. Generation of CNs is of utmost importance in QFD. But, the researches carried out so far have mostly focused on QFD application; post the generation of CNs. Moreover, QFD involves uncertainty and vagueness and thus an option like fuzzy integration is highly asked for. Even the existing software's fails to provide this much-needed support. In this regard, the paper presents the development of one such novel software tool. The proposed tool fills these gaps by providing affinity support feature to generate CNs and facilitates the fuzzy support through Symmetrical Triangular Fuzzy Numbers (STFNs) to deal with uncertainty and vagueness. The tool is designed and built using VB.Net and MS-Access and the implementations are presented and discussed. The tool facilitates viewing output in graphical form and printing reports. The tool provides all the needed database operations.

An example is presented through the developed tool using a sample set of data to specify its effectiveness. Data was gathered using questionnaire and then are fed into the software tool. Through the filtering and affinity module, the collected data was processed to transform CVs into CNs. A total of 14 CNs

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

were finalized and were then grouped under four labels as 'Aesthetics,' 'Functionality,' 'Serviceability' and 'Security.' Two competitors 'F1' and 'F2' were considered for evaluation of Own Firm - 'OF'. The generated outcome was assessed by means of both crisp and fuzzy approach and the comparisons were discussed. The results indicate that using both the approaches 'Security' has appeared as most important factor followed by 'Functionality' and 'Serviceability'. It is also realized that the results produced by fuzzy approach proves handy as they are more precise and accurate as compared to crisp approach. Fuzzy approach presents values in range and thus provides broader view to the decision makers. This strongly assists in effective decision making leading to better website design and development. The existing approach doesn't include the correlations of customer needs and design requirements into computation of final results. The future efforts will involve implementing these correlations with the existing approach and evaluating their effect on overall computations especially on the fuzzy generated outcomes.

Chapter 35
The Use of Written Descriptions and 2D Images as Cues for Tactile Information in Online Shopping

Flor Morton
Universidad de Monterrey, Mexico

ABSTRACT

Despite the steady growth in the use of online platforms for purchasing products in the past few years, e-commerce faces important challenges such as the inability of physically experiencing a product, specifically the inability to obtain tactile information. In this chapter, through a qualitative exploratory study approach, the author explores the possibility of conveying tactile characteristics of a product to consumers in an online shopping environment through product presentation formats such as written descriptions and 2D images. The author highlights the potential for sensory marketing through first reviewing literature on the subject with a special focus on touch and the inability to touch in online commercial channels. The methodology is presented along with the findings of the exploratory study. A concluding discussion of findings is presented and the potential for future research in the area of image processing to enhance 2D images ability to provide tactile information is discussed to conclude the chapter.

INTRODUCTION

According to a study of the Pew Research Center (2016) roughly 79% of Americans say they purchase online, in 2015 they were spending around 350 billion dollars annually online. In Mexico, although at a lower rate, the use of e-commerce is constantly growing. For instance, from 2013 to 2015 the estimated number of sales through e-commerce raised from 9.2 billions of dollars to 16.2 billion dollars, respectively (AMIPCI, 2016). The principal product categories purchased online are fashion products, such as clothing and accessories, sought primarily by females under 35 years old, (Treviño & Morton, 2016).

Despite steady growth, e-commerce faces some challenges related to the forms available to consumers for evaluating products. For instance, marketing literature has found that touch is a direct form in examining products (Peck & Childers, 2003b). However, in today's online environment consumers are unable to physically experience the products and, for example, use their sense of touch for product evaluations and they must rely mainly on written descriptions and visual cues obtained through 2D images such as pictures and videos to obtain information of the products.

Despite the importance of the tactile information for consumers' evaluations and the effects of the information obtained through the haptic system on other consumer's variables such as perceptions and behaviors (Grohmann, Spangenberg, & Sprott, 2007; Guéguen & Jacob, 2006; Krishna & Morrin, 2008, Peck & Shu, 2009), almost no research on whether it is possible for consumers to obtain tactile information in an online shopping context through images, videos, or other types of stimuli has been conducted. Hence, the purpose of this work is to explore how consumers try to compensate for the missing sensory -specifically tactile- experience in an online shopping environment. That is, the characteristics of products can be discovered through the available sources of information that can provide effective somewhat equivalent information.

This book chapter contributes to the marketing literature which recognizes the importance of touch for consumers, but presents a research opportunity of exploring how to compensate touch in an online environment. Additionally, this chapter contributes to the image processing literature by exposing a relatively unexplored business application of the use of 2D images. Particularly, the chapter will explore the possibility of conveying tactile characteristics of a product to consumers in an online shopping environment through 2D images. Furthermore, practical implications of this research are also discussed.

This chapter is structured as follows: First, the chapter presents a literature review on sensory marketing with a special focus on touch and the inability to touch in online commercial channels. The research questions guiding the study are also presented. Second, the methodology of the exploratory study is described. Third, findings of the exploratory study are presented. Finally, conclusions and future research are discussed with a particular call for future research in the area of image processing and establishing the importance to develop techniques that enhance 2D images ability to provide tactile information.

BACKGROUND

Sensory Influences on Consumption

An increasing area of interest in the field of consumer behavior is the role that human senses play in the consumption context. Some of the research in this field of study has focused on the influences of vision on consumers' behavior and perceptions. For example, it has been found that the shape of the package or container can influence serving size and consumption (Wansink & Van Ittersum, 2003). Also, previous findings suggest that more attractive packages are perceived as larger in volume than less attractive packages with the same volume (Folkes & Matta, 2004). There is also evidence suggesting vision can bias product taste perceptions (Hoegg & Alba, 2007). Research focused on smell found this sense can influence information processing, store evaluations, memory of product information, consumption, and satisfaction. For example, researchers quantify that ambient scent influences consumer processing and decision making; specifically, consumers spend more time processing information and are more holistic in their processing (Mitchell, Kahn & Knasko, 1995). Likewise, other findings reveal evaluations of a store

EBSCOhost - printed on 2/8/2023 2:15 PM via . All use subject to https://www.ebsco.com/terms-of-use

and its products as well as purchase intentions are positively influenced by pleasant or neutral ambient scents (Spanenberg, Crowley & Henderson, 1996). Other results suggest that evaluations of the store environment, impulse buying, and satisfaction are increased when scent and music are complimentary in their arousal characteristics (Mattila & Wirtz, 2001). Product scent is more effective than ambient scent in increasing long-term memory of product information according to another study (Krishna, Lwin & Morrin, 2009). Even more relevant to our study, researchers have looked at the congruence between scent and touch properties of a product, findings suggest that congruency between these two properties improves haptic perceptions and product evaluations (Krishna, Elder & Caldara, 2010).

Research focusing on the influence of the sense of touch on consumers has been gaining relevance among consumer researchers because of the importance that this sense has on the consumption process. As previously mentioned, this book chapter focuses on this particular human sense and how alternative channels for consumption such as e-commerce face a challenge of providing the tactile product information and characteristics that influence consumer's perceptions and behavior.

Marketing Literature on Touch

In this section, some of the studies that marketing scholars have made about touch are presented in order to provide an overview of what has already been studied on this topic. From this literature review three general studied variables in the touch and marketing research were found, including: individual differences, perception, and consumer's response/behavior.

Touch and Individual Differences

Previous researchers concentrated on the individual differences in haptic information processing. For example, Peck and Childers (2003b) identified differences among people in their level of preference to use the sense of touch, since these differences could explain why some people are more haptic oriented than others, and reveal the effects of this predisposition on consumer's behavior. The authors developed the concept of need for touch (NFT) and a scale to measure it. Specifically, NFT refers to "a preference for the extraction and utilization of information obtained through the haptic system" (p. 431). According to these authors, NFT has two dimensions: (1) autotelic, in which touch is hedonic oriented and an end of itself; and (2) instrumental, which refers to outcome-directed touch. Moreover, motivation to obtain haptic product information can be influenced by factors such as: product characteristics, individual differences, and situational characteristics (Peck & Childers, 2003a). For example, it has been found that tactile input has a positive influence on product evaluations; in particular, for products with characteristics best explored by touch, such as clothes (Grohman, Spangenberg, & Sprott, 2007).

Additionally, previous research indicates variables such as gender and fashion innovativeness can have an influence on NFT (Cho & Workman, 2011). Consistent with these findings, Citrin, Stem, Spanenberg and Clark (2003) found gender has a significant effect on the need for touch in product evaluation. Specifically, women were shown to have a higher need for touch than men.

Other studies confirm there are differences between consumers high in NFT compared to those with lower levels. For example, consumers with high levels of NFT prefer sales channels where product touch is available, such as physical stores (Cho & Workman, 2011). In particular, there has been found a negative relationship between need for touch and the use of Internet for product purchasing (Citrin, Stem,

Spangenberg & Clark, 2003). Suggesting that high need for touch individuals may not easily adapt to non-touch shopping scenarios, such as the Internet (Peck & Childers, 2003a).

Touch and Perception

The influence of touch on consumers' perceptions as also been addressed in marketing field literature. Interestingly, Peck and Shu (2009) observed when consumers touch a product, even if only in their imagination, perceived ownership of that product increases. As a result, product valuation also increases, especially if the product provides neutral or positive (pleasurable) sensory feedback. These findings provide important considerations with respect to touch and imagination, suggesting that touch can be imagined in a context where tactile input is not available such as the Internet.

Need for touch has also been studied in the area of fashion and clothes; studies in this area have surveyed the impact of visual and tactile attributes. Specifically, visual product aesthetics are considered to serve to make inferences about other sensory characteristics such as tactile attributes; a positive relationship between a person's NFT and the importance or centrality of visual aesthetics has been found (Workman & Caldwell, 2007). Interestingly, attitudes, product evaluations, and purchase intentions have been found to be significantly more impacted or influenced by tactile than by visual information, particularly for products salient on haptic properties (Balaji, Raghavan, & Jha, 2011). Therefore, it is not surprising the negative relationship between need for touch and the use of Internet for product purchasing (Citrin, Stem, Spangenberg & Clark, 2003). Nevertheless, it would be interesting to find ways to provide tactile cues on Internet stores that could diminish this negative association.
